edge of the circular plate at which the arm CG now stands is noted, and the arm CG is to be moved round through 90 degrees of the circular plate upwards; when the arm CG is arrived at this second position, it is in the line of the greatest inclination of the stratified rock. The arm which bears the spirit level EF is then to be raised, by turning it on the centre of the quadrant, and when the bubble stands in the middle of the level, the arm will indicate, on the limb of the quadrant, the degree of inclination of the stratified rock. The magnetic needle in the box OO will, at the same time, show the magnetic azimuth, formed by the vertical plane, which contains the angle of greatest inclination; and this magnetic azimuth is to be converted into true azimuth by applying the number of degrees that the needle varies from the true meridian, at the particular time and place where the observation is made. The box OO has both the top and bottom made of glass, so that the needle may be observed both when the instrument is placed on the upper surface, and when the instrument is applied to the under surface of an inclined plane. When the instrument is not in use, the arm CG, with the quadrant and compass, are unfixed, and taken off from the circular plate, by withdrawing the catch of the bolt which is seen at *d*. The compass box OO is turned round an axis, which is seen below the spirit level EE, so that the compass-box comes into plane with the quadrant, and then the quadrant, compass-box, and arm, CG, pack into a flat box. The circular plate ACS is now separate from the other parts of the instrument, and lies flat in another part of the box made for packing the instrument. Lord Webb Seymour's account of this instrument is published in the *Transactions of the Geological Society*, Vol. III. 1816. (v.)

KOOKIES, or LUNGTAS, the name of a barbarous race, who live among the mountains to the north-east of the province of Chittagong, in Bengal. They are but little known to the inhabitants of the plains, with whom they rarely have any intercourse, except when they occasionally visit the markets on the borders of the jungles in the Runganeeah and Aurungabad districts, to purchase salt, dried fish, and tobacco.

Of all the various tribes which have yet come to the knowledge of the British in these mountains, the Kookies are perhaps the least civilized. Their chief employments are war and the chase; and, like all mountaineers who are of roving habits, and inured to fatigue, they are of an active muscular make, but not tall. They have the peculiar features of all the natives of Eastern Asia, namely, the flat nose, small eye, and broad round face. Their political union seems to be extremely imperfect, being divided into a number of distinct tribes, totally independent of each other, though they all acknowledge the authority of three different Rajahs. The power of these rulers, however, is very limited, excepting in the tribe with which they live, where it is absolute. The dignity is hereditary, and it belongs to the Rajah, in cases of general danger, to summon all the warriors to arms. Each tribe is under the command of its own chief, who is abso-

lute both in war and peace, and has the power of life and death. This office is elective; though, in general, the chieftain is succeeded by his nearest relation.

Kookies.

The Kookies are armed with bows and arrows, spears, clubs, and *dans*, a species of hand-batchet, which, in close combat, is a most destructive weapon. They have shields of cow-hide, and use various devices, in order to render themselves hideous to their enemies. Their villages are built on the steepest and most inaccessible hills, by way of precaution against any sudden attack. As a farther security, they are surrounded with a thick bamboo pallisade, and the passages leading into them strictly guarded both day and night, more especially if there is any suspicion of danger. But, in all cases, they are extremely unwilling to admit strangers within the limits of the fortification. Every village belongs to a tribe, which consists seldom of less than 400 or 500 inhabitants, and sometimes of 1000 or 2000.

This barbarous race is involved in perpetual hostility, not only from the quarrels of their Rajahs, but from the depredations committed on each other by the different villages, and their constant refusal to give up the guilty persons. In these cases a petty and destructive warfare ensues, which is carried on with all the secret stratagems and barbarous devices of savages. Their favourite plan is to approach their enemies secretly and by night marches; after they come within sight of their prey, they lurk in ambuscade till dawn, when they commence their attack with a great shout, striking their spears against their shields, and, in all cases where they are successful, they massacre indiscriminately man, woman, and child. On some occasions where they spare the children, they adopt them into their own families; and the only slaves among them are the captives thus taken.

The Kookies are of the most vindictive disposition, and, in all cases, they require blood for blood. To such a length do they carry the principle of revenge, that if a tiger should happen to kill any of them, the whole tribe sets out in pursuit of him, and they never rest until they kill this or some other tiger in retaliation. They are much occupied in the chase, and as they are restrained by no prejudice of cast or sect, they shoot indiscriminately all sorts of animals. Part of their attention is also directed to agriculture; but in this the women perform the chief part of the drudgery. They have no coins among them, and their trade is, in consequence, carried on by means of barter. They have an idea of a future state of rewards and punishments. But their notions are confused and superstitious; and they imagine that the surest road to the favour of the Deity is by destroying the greatest number of their enemies.

The *Asiatic Researches*, Vol. VII. contains an *Account of the Kookies, or Lungtas*, by John Macrae, Esq. whose information was derived from a native of the Runganeeah district, who, when a boy, was carried off by the Kookies, and succeeded, after a captivity of 20 years, in returning to his family.

Laccadives
Lagrange.

LACCADIVES, an archipelago of low islands lying off the Malabar, or western coast of India, between the 8th and 13th degrees of N. lat. There are nineteen considerable ones; but as most of them are surrounded with reefs and steep rocks, with a great depth of water close to them, the approach to them is very dangerous. Between these islands there are many channels, through which ships from India, bound to Persia or Arabia, frequently sail. The safest of these is called Mamale, or the Nine degrees channel, which runs between the islands of Senhili-par and Kalpenny. The largest of these islands is about 7 miles in length, and $2\frac{1}{2}$ in breadth. Most of them are inhabited by a race of Mahometans called Moplays. They do not yield grain, but produce an infinite quantity of cocoa nuts, from the husk of which they form the Coir cables, which are more elastic and durable than hemp, as the sea-water, instead of rotting, preserves them. These islands are well supplied with fish, and carry on a trade with the small shells called *cowries*, which pass as coin all over India. They are nominally dependent on Cannanore; but their poverty has been always their chief security. They were discovered by Vasco de Gama, in 1499; but have been little frequented by Europeans.—*Edinburgh Gazetteer, or Geographical Dictionary.*

LAGRANGE (JOSEPH LEWIS), a mathematician and astronomer of the first rank, born at Turin, 25th January 1736, was the son of Joseph Lewis Lagrange, treasurer at war, and Maria Theresa Gros, only daughter of a rich physician at Cambiano.

He was the eldest of eleven children, but nine of them died young. His family was of French extraction on both sides, and his French biographers have dwelt with pleasure on the minute particulars of their emigration, in order the more fully to authenticate their own claim to the honour of calling him their natural as well as adopted countryman. It was his great-grandfather that first settled at Turin, in the service of Emmanuel II., who married him to a Roman lady of the family of Conti. They had at one time acquired considerable affluence; but his father had ruined himself by his expenses and speculations; and Lagrange used frequently to observe, that he owed his own success in life to his father's misfortunes, since, if he had been rich, he should never have applied to the mathematics as a profession. The classics were at first his favourite study at the College of Turin: he began his scientific education with reading the works of the ancient geometricians, and at first preferred their methods of investigation to the more modern analysis; but being convinced, as it is said, by a paper of Halley in the *Philosophical Transactions*, of the superiority of the algebraical mode of representation, he applied with redoubled ardour, at the age of seventeen, to the study of the later improvements in the methods of investigation; and in his subsequent works, he abandoned, wherever it was practicable, all geometrical considerations, and seems

to have valued himself on having produced a complete system of mechanics, free from the incumbrance of any diagram whatever. When he was only nineteen, he was made Professor of Geometry in the Royal School of Artillery, but not before he had exhibited, in his first publication, a specimen of the improvements which he was throughout his life to contribute to the mathematical sciences.

The friendships which he formed with his pupils, most of whom were his seniors, led to the establishment of a society which afterwards received the sanction of the royal authority, and to the publication of their memoirs, in which Lagrange not only took the most active part as a contributor of original papers, but also by materially assisting in the demonstrations of Foncenex, and promoting the researches of Cigna and Saluces. Foncenex was soon rewarded by being placed at the head of the maritime establishment which the king was then forming; and Lagrange received in a short time a still more flattering remuneration, in the panegyrics, which were liberally bestowed on him by his great rivals Euler and Dalember: the former procured him, in 1759, the compliment of being made a foreign member of the Academy of Berlin, having become well acquainted with his merits by an epistolary intercourse, which began as early as the year 1754, when Lagrange communicated to him his first ideas of the solution of isoperimetrical problems, which Euler had the delicacy to allow him time to complete, before the publication of his own further researches on the subject.

In 1764, he obtained a prize from the Academy of Sciences at Paris for a memoir on the difficult subject of the libration of the moon, having treated it by an original method, derived from the principle of virtual velocities, which he afterwards applied so successfully to other branches of mechanics. Soon after this time he found an agreeable relief to the monotony and retirement of his life at Turin, in accompanying his friend the Marquis Caraccioli, who was appointed Ambassador at the Court of London, as far as Paris, where he had the delight of becoming personally acquainted with a number of the most distinguished mathematicians of the age, who were capable of appreciating his merits, especially with Clairaut, Dalember, Condorcet, Fontaine, Nollet, and the Abbé Marie; but indisposition prevented his going on to England, as he had intended, and he returned to Turin after a short stay in France. A second prize, on the subject of the satellites of Jupiter, was awarded him in 1766; and the same tribute was again paid to his merit on three subsequent occasions. It was in this year that he was invited to Berlin, as a successor to Euler in the place of Mathematical Director of the Academy, Euler having been induced to remove to Petersburg, by a better prospect of providing for his numerous family. The appointment of President of the Academy, held by Maupertuis, had been given but in part to Euler; the whole was offered to Dalember, who declined it; but both he and

Lagrange.

Lagrange. Euler united in recommending Lagrange as the fittest person for the situation. It was, however, with some difficulty that he obtained his sovereign's leave to quit Turin; and the favour was at last granted to him partly in pique, on account of the terms of the invitation, which expressed the desire of the "greatest king in Europe" to have the greatest mathematician at his court.

At Berlin he pursued his career of study in tranquillity and without interruption, upon a competent income of about L. 300 a year, with the advantage of such demonstrations of the royal protection, as were still more important than income to his rank in society. The king seems to have preferred him to Euler, as more tolerant in his opinions, though by no means joining in all the innovations of the day, and rather avoiding every discussion relating to them, as well as any great familiarity with his patron. He was made, in 1772, one of the eight foreign associates of the Parisian Academy. He is said to have married more for the sake of complying with the universal custom of his friends and colleagues at Berlin, than for any desire of female society; and he invited a relation of his own from Turin, who became his first wife; but she was soon after carried off by a lingering disease. He was about this time very closely employed on his greatest and best work, the *Mécanique Analytique*; but it was with some difficulty that the Abbé Marie found a bookseller at Paris, who agreed to undertake its publication, and only upon condition of engaging himself to divide the loss, in case of failure in the sale. He also procured the valuable assistance of Mr Legendre as a corrector of the press.

Upon the death of Frederic, in 1786, Lagrange no longer felt the same interest in remaining at Berlin, though he was not treated by the new court with any thing like disrespect. While the ministers of Naples, Sardinia, and Tuscany, were making him offers on behalf of their respective sovereigns, Misa-beau persuaded the French ambassador at Berlin to recommend Mr de Vergennes to invite him to Paris; but it was in reality through Mr de Breteuil's interest, and at the suggestion of the Abbé Marie, that he was ultimately induced to settle there, in 1787, having received a grant of an income equal to that which he had enjoyed at Berlin, under the name of a veteran pensioner of the Academy, with a vote in its deliberations. He was kindly received by Marie Antoinette, on account of his connexion with Germany; and, until the Revolution, he had the use of apartments in the Louvre.

It was at this period of his life, when his success had been the most gratifying, and his fame had become perfectly established, that he appeared to suffer under a degree of melancholy or apathy, which was absolutely morbid. He confessed that all his enthusiasm was extinguished, and that he no longer felt the least relish for mathematical researches. He had not even the curiosity, for two years, to open the printed volume of his *Mechanics*, which he had never seen except in manuscript. It is a consolation to think, that this annihilation of his energies was only partial and temporary: he amused himself in the mean time with metaphysics, "with the his-

tory of religion," and of languages, and with medical and botanical, and especially chemical studies; and the alarms and agitations of the Revolution, which soon followed, instead of overwhelming his broken spirits, seem to have roused his dormant powers, and to have revived his satisfied ambition, exciting him to new labours and new triumphs.

In 1791, his name appeared on the list of the foreign members of the Royal Society of London. Mr Maurice has asserted, that all the scientific bodies of Europe, *except* the Royal Society, received him with open arms: if the remark was intended as a censure of that society, it is right that its injustice should not pass unnoticed.

Notwithstanding the public embarrassments which attended the Revolution, Lagrange's pension was confirmed by the National Assembly, upon the proposition of Mr Duscjour, in the most flattering manner: and when the depreciation of the currency materially reduced its amount, he received a partial indemnification, by being appointed a member of a committee for examining useful inventions, and afterwards a Director of the Mint, in conjunction with Berthollet and Mongez: but this employment he found too laborious, and resigned it six months afterwards. He was greatly interested, at this period, in the establishment of the new system of weights and measures: he was so violently bent on *decimation*, that he scarcely forgave Borda for having made a measure of a quarter of a metre, and he thought so little of the advantage of integral subdivisions, that he sometimes declared he should have preferred the number 11 to 12, for the very reason that it admitted no subdivision at all, and caused all lesser quantities to be expressed in units comparable to each other only. This opinion seems, however, to have been advanced rather as an exaggerated objection to the introduction of 12, which was suggested by some more ardent innovators, than as seriously attributing a real advantage to the employment of a prime number.

When the Academies were suppressed, the Jacobins purified the commission of weights and measures by striking out the names of many of its most distinguished members, while they retained that of Lagrange, probably because he was of no political party whatever, and had always been particularly cautious in expressing his sentiments of the events of the day. In October 1793, however, a decree was passed which ordered all persons, not born in France, to leave the country. Guyton, who was a member of the Committee of Public Safety, advised him to claim an exemption from its operation, by a requisition of that committee, on the pretext of his being employed in preparing a report on Dr Hutton's *Treatise on Gunpowder*; and he actually received an injunction from the committee, requiring his stay, "in order to complete the calculations which he had undertaken respecting the theory of projectiles." He was attempting to reunite the experiments of Dr Hutton with a more correct theory than had before been applied to them; but he published nothing of importance on the subject. After the murder of Bailly and Lavoisier, he had agreed to return to Berlin, and to resume his former situation

Lagrange.

there; and he was on the point of obtaining a passport, and even a public mission from Hérault de Sechelles. But the establishment first of the *Normal School*, in which he was a professor, and then of the *Ecole Polytechnique*, induced him to remain at Paris, and again directed his activity into its ancient channels. In the Normal Schools the masters were mixed with their pupils, in order that the facilities of conversation might produce a developement of the subjects discussed in the most elementary manner that was possible: but the conversation was by no means supported in the form of incessant questions and answers: Lagrange's explanations were often interrupted by moments of silence, in which his inventive faculties were deeply engaged in reflection, and the whole of his powers were concentrated on a new train of ideas. It was amidst these discussions that the *Theory of Analytical Functions* originated: a work certainly not destitute of the marks of great mathematical talent, but which, when considered as a substitute for the method of fluxions and its kindred doctrines, resembles very much the suggested introduction of an undecimal in preference to a duodecimal scale of notation, with which the author had before amused himself.

Upon the re-establishment of the Institute, Lagrange was made one of the original members; and he was the first on the list of the Board of Longitude, which was then first instituted at Paris. He received about this time a compliment highly grateful both to his love of fame and to his filial affection, in the person of his father, then past 90, and continuing to reside at Turin. By the direction of Talleyrand, who was Minister for Foreign Affairs, the Commissary of the Directory in Piémont, attended by the generals of the French army, and several other persons of distinction, went in procession to congratulate this venerable person on the merits of his son, whom he had not seen for more than 30 years, whom they declared "to have done honour to mankind by the brilliancy of his genius, and whom Piémont was proud to have produced, and France to possess as a citizen." The old man lived to the age of 95, and was sincerely regretted by his son.

Under the Consular and Imperial government, Lagrange was made a Senator, a Grand Officer of the Legion of Honour, a Count of the Empire, and a Knight Grand Cross of the Order of Reunion, in addition to the personal marks of friendship and intimacy which Bonaparte habitually conferred on him at the meetings of the Institute, and on other occasions.

He applied with so much zeal to the republication of the first part of his *Mechanics* in 1811, and of his *Analytical Functions* in 1813, that his health is supposed to have suffered from the fatigue; which, in conjunction with a predisposition, not uncommon in advanced life, may very possibly have been the immediate cause of a fit that attacked him in the beginning of the latter year. In the month of March he was subject to frequent returns of fainting, accompanied by some fever. On the 8th of April he had a last conversation with Lacépède, Monge, and Chaptal, all the parties being aware that it was to be the last. He felt the approach of death, but he declared that it was in that form neither vain-

Lagrange.

ful nor even disagreeable. He spoke with proper gratitude of the favours he had received from Bonaparte, who afterwards provided very liberally for his widow and his brother. The interview lasted more than two hours, and though his memory often failed him with respect to names and dates, yet his language was correct and energetic. He survived this effort only two days, and died on the morning of the 10th April 1813. He was buried at the Pantheon, or the church of St Gèneviève, and his friends Lacépède and Laplace paid the last honours to his memory in a funeral oration.

Lagrange was habitually of delicate health, and extremely temperate in his diet and mode of life limiting his food almost entirely to vegetables, and taking his exercise very punctually in the open air. At the age of 56 he married the young and handsome Miss Lemonnier, who appears to have felt the splendour of his celebrity and the goodness of his heart, as affording much more than a compensation for the great inequality of their ages. He was deeply sensible of her affectionate attachment, which he considered as the greatest happiness of his life and on account of which alone he regretted its termination. He had no children, and he was perfectly contented to be without them. In the midst of the most brilliant societies he was generally absorbed in his own reflections; and especially when there was music, in which he delighted, not so much for any exquisite pleasure that he received from it, as because, after the first three or four bars, it regularly lulled him into a train of abstract thought, and he heard no more of the performance, except as a sort of accompaniment assisting the march of his most difficult investigations, which he thus pursued with comfort and convenience. He was less fond of the theatre, from which he often returned without knowing what piece had been represented. His manner in conversation was gentle and timid: he was more in the habit of interrogating than of giving his opinion, and his favourite expression was, "I don't know".... He was not, however, easily induced to change his sentiments when they were once fixed, having generally adopted them upon mature consideration. As a writer, whenever any controversy occurred, he was always calm in defending himself, and respectful in speaking of his antagonists. Notwithstanding that his person was striking and characteristic as well as pleasing, he would never consent to have his portrait painted, thinking it unworthy of a man of intellectual excellence to wish to be remembered for the external form of his features. But a sketch of him was once obtained by stealth at a sitting of the Institute, and a mask of his face was taken after his death. His works bear witness that for 54 years he occupied either the first or very nearly the first place among all the mathematicians of his age, and of all ages. "Of all the inventors," says Laplace, "who have the most contributed to the advancement of human knowledge, Newton and Lagrange appear to me to have possessed in the highest degree that happy tact, which enabled them to distinguish general principles among a multitude of objects enveloping them, and which is the true characteristic of scientific genius. This tact, in La-

Lagrange. grange, was united with a singular elegance in the method of explaining the foundations of the most abstract truths of analysis." Lagrange was a great admirer of Euler, who perhaps excelled him in the adroitness with which he employed the most refined artifices of calculation, though his views and methods were less original and less powerful. D'Alembert was highly esteemed by Lagrange, as a man of abundant ingenuity and talent, though less accurate in his conclusions, and in his modes of reasoning, than either Euler or Newton. Newton he envied almost as much as he admired, for having found a system of the world in existence, and the principles of its modification not yet understood: but when it is remembered that the places of the heavenly bodies are now ascertained to seconds more nearly than they were to minutes during the life of Newton, it cannot be thought that Newton left too little for his successors to accomplish.

1. His first publication, at the age of 18, was, *A Letter to C. J. Fagnano*, 23d June 1754. It contains series for fluxions and fluents of different orders, somewhat resembling the binomial theorem of Newton.

2. The series of his papers in the *Miscellanies of Turin* is continued from 1759 to 1785. The first is *On Maxima and Minima*. *Misc. Taur.* I. 1759, p. 18. It is founded on the principles laid down by Maclaurin, and is illustrated by the case of the successive transmission of an impulse through a series of elastic bodies, comprehending the combination of a number of variable quantities. 3. *On an Equation of finite differences, and on the Theory of recurring Series*, p. 33. The equation is resolved by an exponential integral, and the sum of the series is obtained by the principles of fluxions: the same mode of calculation is also applied to the laws of chance. 4. *Researches on the nature and propagation of Sound*. End of the volume. The investigations of Taylor and of Newton were true and correct as particular solutions only of the problems of chords and of undulations, though mistaken for general solutions, and as such successfully combated by Cramer, whose reasoning, though certainly too far extended, is here approved by Lagrange. Daniel Bernoulli very successfully defended them both, not only as particular solutions, but as capable of being rendered universal by proper modifications and combinations. Euler had proposed a more general construction for the case of chords; D'Alembert insisted that this method required a limitation to figures exempt from angles and from abrupt changes of curvature, and Lagrange is inclined to admit his exceptions. But, after all, the question is merely a metaphysical refinement, since no abrupt changes can ever occur in the actual form of a chord; and a chord affording a harmonic of unlimited acuteness will approach without limit to a mathematical angle. The author begins, in the essay, with considering the motions of a finite number of bodies, and then proceeds to the affections of a fluid, which he reduces to the same equations as are applicable to the motions of chords, and these he integrates in D'Alembert's manner. He lastly examines the phenomena of the grave harmonics observed by Tartini,

and explains them very satisfactorily from the analogy of the beats of discordant sounds. 5. *New Researches on Sound*. *Misc. Taur.* II. 1760-1. p. 11. The same subject is here continued, and extended to the divergence of sound, which had before been examined by Euler. The author now admits that there is no inconsistency in the demonstration of Newton and Cramer, which deduce the same velocity from different laws of the supposed motion, since the velocity is really uniform in all cases. The oscillations of a heavy chain are computed, and some remarks are made in conclusion respecting the sounds of flutes. 6. *On the Maxima and Minima of indefinite integrals*, p. 173. This essay contains the foundation of the method of independent variations, which has excited so much attention for the universality of its application and the utility of its results. It was received with distinguished applause by Euler, as fulfilling his own wishes for the extension of a similar method; and it was Euler who more fully explained its principles, and gave it the name of the method of variations, which has since been generally applied to it. In fact, however, the foundation of the method had long before been laid by Leibnitz, under the name of differentiation from curve to curve; and he had proved that the process of integration, with respect to one kind of variation, might be applied to the differentials or fluxions taken in another manner, without the necessity of first obtaining the fluent: and Euler had employed this consideration in treating of the geometrical properties of curves affording maxima or minima: but his method is less simple and less general than that of Lagrange, who first pointed out the universality of the principle, that the variation of the fluxion is equal to the fluxion of the variation, and showed its utility in many cases of such integrations, as leave the expression concerned still a fluxion of another kind: and in the mechanical application of the method, he made the fluxion of the ordinate of a vibrating chord represent its inclination to the axis at any given time, while its variation indicated its velocity or its change of place in successive intervals of time, and the fluxion of a revolving solid to relate to the magnitude of its different parts, while its variation depended on its rotatory velocity. The steps of the method are generally simple and easily understood, at least they may and ought to be rendered so; but the merit of the invention is not the less, because it admits of a very ready application, and because it might have occurred to a less distinguished mathematician; as indeed something nearly resembling it seems to have been employed by Fontaine in 1734, under the name of the fluxiodifferential calculus, in the investigation of a tautochronous curve. 7. It was particularly in demonstrating the law, which is called the law of the least action, that Lagrange completed the theory of variations, where Euler had felt its deficiency; and the application of the method to several *Mechanical Problems* constitutes the second part of the *Memoir*, p. 106. The author takes occasion also to correct an error of D'Alembert, who had imagined that there was no necessity that the different strata of a given density, in a body like the earth, supposed to be in a state of

Lagrange.

fluidity, should all be level, which, however, is here shown to be a necessary consequence of D'Alembert's own equations. 8. *Addition to the memoir on Sound*, p. 323; admitting the difficulty raised by D'Alembert, respecting the continuity of the figure of a chord, and acknowledging that the initial figure must not be supposed angular; while, in fact, as Mr Fourier has lately demonstrated, and as had been remarked many years ago in this country, an infinite series of harmonic curves may approach infinitely near to two right lines meeting in an angle. 9. *Problems relating to the integral calculus*, *Misc. Taur.* III. 1762-5, p. 179. A miscellaneous paper, containing remarks on the resolution of equations, containing fluxions of different orders; on some cases of the motions of fluids; on the vibrations of chords; on the properties of small oscillations in general; on loaded threads; on central forces; and on the theory of Jupiter and Saturn. 10. *An arithmetical problem*, *Misc. Taur.* IV. 1766-9, p. 44. This paper, dated at Berlin, contains a complete resolution of all equations of the second degree, having whole numbers for their roots; a problem, like most of those of Fermat, of more curiosity than utility, but well calculated to exercise the powers of minds like those of Euler, Lagrange, Legendre, and Gauss. The question, which is the particular subject of this paper, was proposed as a challenge by Fermat to his contemporaries in England, and correctly answered by Wallis, though without a very satisfactory demonstration. 11. *Integration of an Equation*, p. 98. A case in which the whole equation is integrable, though its parts, even when properly separated, are incapable of perfect integration. 12. *On the method of variations*, p. 163. In answer to Fontaine, and to Le Séjour and Jacquier, who had attacked him in their Integral calculus. 13. *On the motion of a body attracted by two fixed centres*, p. 188, 216, including the effects of different supposed laws of attraction. 14. *On the figure of columns*, p. 123. This memoir contains an attempt to demonstrate that the cone is a more advantageous figure for the strength of a column than any conoid, and the cylinder than any cone. But the calculations are founded on the erroneous supposition, that the column must bend before it breaks; and, even upon this hypothesis, it appears possible to assign a stronger form than a cylinder, since the summit and the base of the cylinder must certainly contain some useless matter. 15. *On the mean of a number of observations*, p. 167; showing the advantage of taking the mean, from the theory of probabilities. 16. *On the impulse of fluids*, *Mém. Taur.* 1784-5, I. p. 75. The author observes, that this impulse will be measured by a column of twice the height due to the velocity, when the whole impulse of the jet is received by an obstacle, but of the simple height, when a limited surface is exposed to the force of a larger stream. 17. *On the integration of some irrational fluxions*, II. p. 218, involving the square root of an expression ascending to the fourth power of the variable quantity.

18. Some of the later of these papers are subsequent in date to those which are found in the *Memoirs of the Academy of Berlin*; but the order of enumeration is of little consequence. The first communication of Lagrange to the Academy, of which he

Lagrange.

was made director, is *On tautochronous curves*, *Mém. Berl.* 1765, p. 364. The paper is dated 1767; and it contains a completion of Fontaine's investigation of the subject. 19. *On the expected transit of Venus* 1766, p. 265. The author has here analytically investigated the curves of immersion and emersion for the different parts of the earth. But, as Mr Delambre observes, in order to arrive at the very easy and tolerably accurate solution previously given by Delille and Lalande, he is obliged to employ in succession several elaborate expedients, founded on some very subtle principles, accompanied by various transformations of his ordinates, while, by a trigonometrical calculation of a few lines, we may obtain a more complete formula, comprehending even the terms which he has neglected, and which, although very small, are not absolutely insensible. At the same time, he has certainly applied his formula to the calculation of the parallax of the sun, in a very convenient manner, which had accidentally escaped both Delille and Lalande, though it follows readily from the trigonometrical calculation. 20. *On indeterminate Problems of the second degree*, 1767, p. 165. This is the first of a numerous series of papers, relating to this difficult branch of analysis, which, notwithstanding its practical inutility, has afforded sufficient scope for the exertion of talent, to give celebrity to the names of Diophantus and Fermat among the most ingenious of mathematicians. 21. *On numerical equations*, p. 311. This subject was also much cultivated by the author at a subsequent period: he here finds an equation for the differences of the roots, and exhibits the result in the form of a continued fraction. 22. *Continuation of the memoir on numerical equations*, 1768, p. 111. The method of continued fractions is still further improved. 23. *On the resolution of indeterminate problems in whole numbers*, p. 181. 24. *On the resolution of literal equations by series*, p. 251. The contents of these memoirs have been principally merged in the author's later productions. 25. *On the force of springs*, 1769, p. 167. It is demonstrated in this interesting paper, that the force of a hair-spring approaches to the law of a circular pendulum, the more nearly as its length is greater. 26. *On Kepler's problem*, p. 204. An application of the methods explained in the last volume, especially of a very elegant formula for the reversion of series. 27. *On elimination*, p. 303. A refined and general method of exterminating a quantity from an equation, which, however, is somewhat intricate, even in the simplest cases. 28. *Remarks on isochronous curves*, 1770, p. 97. Chiefly in answer to Fontaine, who had attacked him, and who had claimed the invention of the test of integrability of an expression containing several variable quantities. Lagrange observes, that he might very possibly have rediscovered it, but that it was published by Nicolas Bernoulli in 1720; by Fontaine, not till 1738. 29. *On arithmetical theorems*, p. 123, relating to the decomposition of a number into squares. 30. *On the resolution of equations*, p. 134. 31. *On a theorem respecting prime numbers*, 1771, p. 125. A demonstration of the property of prime numbers discovered by Mr Wilson, and published by Waring; and of some other theorems of Waring. 32. *On equa-*

Lagrange. *tions*, p. 138. In continuation. 33. *On a new mode of differentiation and integration*, 1772, p. 185. The novelty consists in considering the characteristic of a fluxion as a quantity multiplying the letter to which it is prefixed, and inferring by induction that the result of the combinations obtained will in general remain unaltered by the supposition. The grounds of this method have been of late more fully explained by Arbogast and others. The results are here applied to interpolations, and to differences of various orders. 34. *On the form of imaginary roots*, p. 222.

In general reducible to $A + \sqrt{-1}B$. 35. *On astronomical refractions*, p. 259; without any practical applications. 36. *On equations of partial differences*, p. 353; especially on finding multipliers to make them integrable. 37. *On undisturbed rotation*, 1773, p. 85. A more direct method of investigation than that of Euler or D'Alembert; but without any new results. 38. *On the attraction of elliptic spheroids*, p. 121. The author observes, that Maclaurin's prize essay is a masterpiece of geometry, comparable to the best works of Archimedes, though D'Alembert had once doubted of the accuracy of some of his propositions. Thomas Simpson's was the first analytical solution of the problem, but it was indirect, and depending on series only. In this paper the method of demonstration only is varied. Legendre and Laplace subsequently continued the inquiry. "But Mr Ivory," says Delambre, "has lately shown us, that a very simple consideration may in some cases supersede a multitude of calculations, and even afford us theorems to which the most prolix computations could scarcely have conducted us." 39. *On triangular pyramids*, p. 149. An analytical determination of the content, and of the figures that may be inscribed in the pyramids, when their six sides are given. 40. *Arithmetical researches*, p. 265; on the integral roots of equations of the second degree. 41. *On particular integrals*, 1774, p. 197. Laplace had already pointed out the occasional occurrence of integrals, not included in the general and direct expression obtained by the usual modes of integration. Such values are here deduced from the variation of the quantities originally considered as constant, which often affords us an equation of a different form, and leads to values not comprehended in the regular expression of the integral. 42. *On the motions of the nodes of the planetary orbits*, p. 276. Euler, Lalande, and Bailly had found some expressions for the temporary change of position of the nodes; the equations are here integrated, and the total changes determined. 43. *On recurring series varying in two ways, or on partial finite differences*, 1775, p. 183. With an application to the theory of chances, upon Laplace's principles. 44. *On spheroids*, p. 273. A demonstration of Maclaurin's theorem (*Fluxions*, Art. 653) concerning the attraction of a compressed spheroid or an amygdaloid; derived from the formulæ contained in the former papers. 45. *Arithmetical researches continued*, p. 323. Demonstrating some theorems of Fermat with which Euler had not succeeded: yet leaving others still unattempted. 46. *On the mean motions of the planets*, 1776, p. 199. Showing that

all their changes are periodical. Laplace had detected an error in the author's reasoning when he attributed secular equations to the motions of Jupiter and Saturn, the expressions, containing the terms in question, being compensated by others which he had neglected. 47. *Cases of spherical trigonometry solved by series*, p. 214. Without any apparent advantage. 48. *On integration by continued fractions*, p. 236. Gives an example of the binomial theorem converted into a continued fraction, which, however, exhibits no particular elegance nor simplicity. 49. *On the number of imaginary roots of equations*, 1777, p. 111. Harriot was the father of the doctrine of equations. Newton made great improvements in it, but his rule remains imperfect with regard to the higher equations, even with the additions of Maclaurin and Campbell. In the present paper the theorem of Waring is demonstrated, without any material attempt to extend it. 50. *On the Diophantine analysis*, p. 140. It is remarked that Fermat left all his propositions undemonstrated, except this theorem, that the sum of two biquadrate numbers can never be a square. 51. *On escapements*, p. 173. An investigation of the best forms of pallets for the dead beat and the recoiling escapements. 52. *On determining the orbits of comets by three observations*, 1778, p. 111, 121. The first part of this memoir is historical and critical, and the author allows due credit to the ingenuity of Newton's method: his own does not appear to have been of any practical utility. 53. *On the theory of telescopes*, p. 163. Comparing the general theorems of Cotes and Euler, and applying the method of recurring series to their demonstration; with a rule for determining the magnitude of the field. 54. *On the expression of the time in a conic section*, p. 181. After Lambert, who determines it from the chord of the arc described, the sum of the revolving radii, and the great axis: the theorem is here analytically demonstrated. 55. *On particular integrals*, 1779, p. 121. Examples from some mechanical curves. 56. *On geographical projections for maps*, p. 161, 186. The methods here proposed for the construction of maps have been found too intricate for adoption. 57. *On the theory of the libration of the moon*, 1780, p. 203. In the prize essay on the moon's libration, the author had made the first application of the method of variations: the investigation is here continued, and it is observed that the moon cannot be of homogeneous matter, nor its form such as would afford equilibrium to a fluid covering it, since the effects of the ellipticity, so determined, would be much less perceptible than they are. 58. *Report on a quadrature of the circle*. *Hist. Ac. Berl.* 1781, p. 17. This paper only requires to be noticed as a specimen of the author's condescension. 59. *Theory of the motion of fluids*, *Mém.* p. 151. An application of D'Alembert's principles to the phenomena of running fluids, and to the motion of waves; but founded on an arbitrary assumption with respect to the depth affected by the waves. 60. *On the secular variations of the elements of the planets*, p. 199. The theory of perturbations is here examined by two methods, either comprehending the general form of the orbit, or regarding the local effects only. 61. *Report on a*

Lagrange. *mode of finding the form of the earth*, *Hist.* 1732, p. 35. A proposal of no value whatever. 62. *On the secular variations of the planets*, *Mém.* p. 169. A continuation of the former memoir, with all the details of the application, and a determination of the change of the place of the ecliptic, together with a demonstration of the permanency of the general arrangement of the system, depending on the exemption of the mean distances from all variations not periodical, while the other elements are liable to greater alterations. 63. *On the periodical variations of the planetary motions*, 1783, p. 161. A sequel to the memoirs on the secular variations. 64. *Additions respecting the secular variations*, p. 191. Completing the examination, and extending it to the case of Jupiter and Saturn, which had before been investigated by Laplace. 65. *On the correction of the errors of astronomical approximations*, p. 224. The errors here considered arise from the employment of the powers of the arcs described in the equations concerned, these arcs increasing without limit: they may be avoided by means of approximations founded on the supposition of the variation of the elements. Laplace had before employed a method still more refined. 66. *On a particular mode of approximation*, p. 279. Resembling that which Briggs employed for making logarithms. 67. *On a new property of the centre of gravity*, p. 290. Relating to the mutual distances of the bodies. 68. *A direct and general determination of the motion of a comet*, p. 296. In this third memoir the problem is reduced to equations of the 8th or 7th degree. 69. *Theory of the periodical variations of the planetary motions*, 1784, p. 187. Continuation of the memoir of the preceding year, containing the independent variations of the eccentricities and inclinations, for the six principal planets; with a numerical application of the formulae demonstrated in the first part. 70. *On the integration of equations of linear partial differences*, 1785, p. 174. Entering into further details of the method laid down in a former paper, which is here applied to the problem of trajectories, a problem once proposed by Leibnitz as a trial of strength to Newton, who was not fully aware of the nature of the difficulty intended to be combated: it was, however, solved in England by Taylor, though indirectly. Nicolas Bernoulli and Hermann gave a more complete solution, and Euler added still more to the generality of the investigation. The author observes that the problem is a mere curiosity; there is, however, one case in which a trajectory of the kind here considered is actually applicable to a natural phenomenon of common occurrence, which is that of a wave diverging from a point in a gradually shelving shore; for the figure or direction of the collateral parts of such a wave may be shown to be the orthogonal trajectory cutting an infinite number of cycloids beginning at the given point. 71. *On the motion of the aphelia of the planets*, 1786, i. A geometrical investigation, in the manner of Newton, intended as an appendix to the *Principia*. 72. *On the theory of sound and waves*. This paper is also intended to complete the demonstrations contained in the same work. The volume, in which both these interesting memoirs appear, seems to have been pub-

lished out of the regular order, from some circumstances connected with the death of Frederic; and it is wanting in many of the British libraries. 73. *Note accompanying a memoir of Duval le Rot*, 1786-7, p. 253. On the secular equations of the Georgian planet. 74. *On a question relating to annuities*, 1792-3, p. 235. The case of an annuity supposed to commence after a death, and to cease at a given age. 75. *Additions to former memoirs*, p. 247. On recurring series (n. 43); on elliptic spheroids (n. 38); on interpolations, in Mouton's manner, comprehending the inequality of the distances of the observations; on the secular equation of the moon (n. 64). After Laplace's great discovery of the cause of the secular acceleration, Lagrange found that it might have been easily deduced from his own calculations, almost in the same form, if he had not accidentally neglected the application, from having assured himself, in 1783, that the results of a similar computation were nearly insensible in the case of Jupiter and Saturn. It was in 1787 that the discovery of Laplace was announced. The acceleration here computed is $10''.5$ for the first century after 1800. Mayer found it $9''$ from a comparison of observations. 76. *On a general law of optics*, 1803, *Math.* p. 3. A demonstration of the foundation of the method long used by English opticians for determining the magnifying powers of telescopes of all kinds, which form an image of the object-glass beyond the eyeglass, by measuring the diameter of that image. The author hazards, in this paper, the very singular assertion, that the illumination of the object must be the same in all telescopes whatever, notwithstanding the common opinion, that it depends on the magnitude of the object-glass; and his reasoning would be correct, if the pupil of the eye were always less than the image of the object-glass in question; since, as he observes, the density of the light in this image is always inversely as the magnifying power; but he forgets to consider that the illumination on the retina, when the whole pencil is taken in, is in the joint ratio of the density and the extent; a consideration which justifies the common opinion on this subject, and shows that a most profound mathematician may be grievously mistaken in his conclusions, if he proceeds to calculate upon erroneous grounds. It deserves, however, to be remembered, that the brightness of any given angular portion of a magnified image must always be somewhat less than that of an equal portion of the object seen by the naked eye: because it can be no greater if the pencil fills the pupil, and will be less in proportion as the pencil is smaller than the pupil, besides the unavoidable loss of light at the refracting surfaces.

77. The later works of Lagrange have principally been published at Paris, and most of them in the various Collections of the Academy. The earliest of these are the prize memoirs, and first the essay, *On the libration of the moon*, which obtained the prize in 1764. *Ac. Par. Prix.* IX. 1772. It is in this memoir that the method of variations was first practically applied to a mechanical problem. 78. *On the inequalities of the satellites of Jupiter*, in 1776. Including the consideration of their mutual perturbations, and consequently a case of the problem of

Lagrange.

Lagrange. six bodies. The author never resumed the subject, but its investigation was completed by Laplace. 79. *A new method of solving the problem of three bodies*, in 1772. 80. *On the secular equation of the moon*, in 1774. *M. Sav. Etr.* VII. for 1773. An unsuccessful attempt, with conjectures respecting the existence of a resisting medium, and even doubts of the accuracy of the foundation of Halley's discovery. 81. A prize memoir, *On the perturbation of comets passing near planets*. *M. Sav. Etr.* X. Par. 1785, p. 65. Finding the path directly, without regard to the conic sections, and employing three different modes of computation for the different parts of the orbit. 82. *On forming tables by observations only*, *Mém. Ac. Par.* 1772, i. p. 513. The method of recurring series is principally employed, and the author observes that the problem is more useful than difficult, giving an experimental example in the equation of time, for which he obtains from the results of the tables an expression very near the truth. Delambre remarks that this is only a continuance of the system adopted by Ptolemy and the other ancient astronomers, showing what we might have done in a circuitous manner by pure mathematics, if Newton and the laws of gravity had not existed; and he thinks the paper only valuable as a specimen of Lagrange's talent for overcoming difficulties, which he might more easily have avoided. 83. *On the nodes and inclinations of the planetary orbits*, 1774, p. 97. With details of the calculations for all the planets. 84. *On the variation of the elements of the planets*. *Mém. Math. Inst.* 1808, p. 1. The object of this paper is to show, as Poisson had done before, that all the changes of the system are periodical. The method is more general, but less simple than that of Laplace, who first discovered the principle by induction. The lunar acceleration is given as an example. Mr Poisson has extended his calculations to quantities of the second order, which do not enter into Lagrange's investigations. 85. *On the variation of independent quantities in general in mechanical problems*, p. 257. The author observes that many of the modern improvements of mathematics depend on the doing away the distinction between constant and variable quantities, which was so valuable when it was first enforced by Descartes. 86. *A second memoir on the variation of independent quantities*, 1809, p. 343. Simplifying the general application of the doctrine.

87. *Lectures on arithmetic and algebra*. *Séances des Ecoles Normales*, year III. 1794-5. The first lecture relates to the elements of arithmetic, the second to the lower orders of equations, and the third to the higher. All these lectures, under the name of conversations, were taken down in short-hand by some of the students, and afterwards corrected by the professors.

88. *An essay on political arithmetic*. Roederer, *Collection de divers Ouvrages*. Paris, an. IV. 1795-6.

89. In the *Journal de l'Ecole Polytechnique*, we find an *Essay on numerical analysis, and on the transformation of fractions*, Vol. II. 1798, p. 95. It contains the elementary theory of continued fractions, and the mode of reducing them. 90. *On the principle of virtual velocities*, p. 115. Chiefly relating to

pulleys. 91. *On the object of the theory of analytical functions*, VI. 1800, p. 232. A detailed explanation of the grounds of the theory laid down in the separate publication on this subject. 92. *Analysis of spherical triangles*, p. 270. Giving all their essential properties in a concise form. 93. *Lectures on the calculus of functions*, XII. 1804. Published also separately in 8vo. A commentary on the theory of functions, and a supplement to it, contained in twenty lectures. 94. *Two more lectures*, XIV. 1808; at the end, chiefly relating to the method of variations. 95. *On a difficulty respecting the attraction of spheroids*, VIII. xv. Remarks which may serve as a commentary on a passage of the *Mécanique Céleste*.

96. *On the origin of comets*. *Connaissance des Temps*, 1814. 97. *On the calculation of eclipses, as affected by parallax*, 1817. From the *Berlin Almanack* for 1782. This memoir, as Delambre observes, is singularly attractive to a person previously unacquainted with the methods which are employed; but though the formulæ first introduced are direct and rigorously accurate, the whole investigation ends in an approximation which wants both these properties.

98. The most important of all the works of Lagrange are those which have appeared in separate volumes; and among these we may reckon his *Additions à l'Algèbre d'Euler*, 8. Lyons, 1774, Vol. II. German, 1796. English, 1797. They relate chiefly to continued fractions, and to indeterminate problems, and constitute the most valuable part of the whole work, which, in its abridged form at least, is far inferior to Maclaurin's *Algebra*. 99. *Mécanique analytique*, 4. Par. 1788, 2d edit. Vol. I. 1811, Vol. II. by Prony, Lacroix, and Binet, 1815. This work exhibits a uniform and elegant system of mechanical problems, deduced from the simple principle of virtual velocities, which was well known to former authors, but never so extensively applied. It has been remarked, that many parts of it may be read with advantage, even by those who are not competent to enter into any of the computations, exhibiting such a history of the progress of the science, as could only have been sketched by a master. The new edition, begun at the age of 75, comprehends all the improvements contained in the author's later memoirs on various subjects. 100. *Théorie des fonctions analytiques*, 4. Par. 1797, 1813. The abstract theory of analytical functions has been very fashionable among modern mathematicians; but the improvements which it contains are chiefly of a metaphysical nature, if they can with propriety be called improvements. The notation is less simple than that which is in common use, and has been abandoned by the author in some republications of the works in which he had at first employed it. The calculations, too, are often more intricate than others which afford the same conclusions. 101. *Résolution des équations numériques*, 4. Par. 1798, 1808. The refined and abstruse speculations, contained in this volume, are more calculated to promote the advancement of the abstract science of quantity, than to be applied, as the title would seem to denote, to the purposes of numerical computation. The methods investigated are in general laborious and complicated, though instructive.

Lagrange. and capable of extensive application; and for equations, of which all the roots are real, the author himself recommends Mr Budan's method, as preferable to his own. The second edition contains a number of very interesting notes, which are full of ingenuity and novelty.

The author of so immense a series of laborious investigations must certainly have been a most extraordinary man. He had acquired the character of an illustrious mathematician almost in his boyish years; and he continued to apply the force of his powerful mind, for more than half a century, to the almost uninterrupted pursuit of his favourite sciences. It seems, however, that his earliest were also his greatest successes; and all that followed was as little as could well be expected, from a continued employment of the means which he possessed at the beginning; for, in fact, the whole taken together appears to bear a stronger character of great industry, than of great sagacity or talent.

"It was formerly usual," says Delambre, "for mathematicians to inquire in every investigation, for some general considerations, which might be capable of simplifying it, or of reducing it to a problem already resolved, and to endeavour by these means either to abridge the calculation, or sometimes to supersede it altogether. But since the discovery of the infinitesimal calculus, the facility and universality of this method, which often renders the possession of ANY TALENT IN THE CALCULATOR WHOLLY UNNECESSARY, has made it more usual for mathematicians to direct their chief attention to the perfection of this all powerful instrument. But at the present day, when researches of this kind appear to be completely exhausted by the labours of Euler, Lagrange, and their industrious contemporaries, it might perhaps be more advisable to return to the ancient method, and to follow the example of" Newton, surely, and of "Daniel Bernoulli, who, as Condorcet observes, was entitled to the praise of moderation in the introduction of his calculations. Lagrange was in the habit of employing his sublime talents in a different manner: he liked to make every thing dependent on his analysis, though, in some instances, he united both methods in the highest degree, as his invention of the calculus of variations bears witness. His reducing the theory of sound to that of the vibration of chords, is a specimen of a very ingenious simplification; as well as his mode of computing the planetary motions by the variation of the elements of their orbits, which is also applicable to all other cases of the operation of small disturbing forces. But it must be confessed, on the other hand, that he has sometimes created difficulties where none existed, by applying his profound and ingenious methods to the solution of elementary problems, which may be obtained from a construction of the simplest kind; and the powerful agents which he employs, on many trifling occasions, remind us only of the man in the fable, who came to borrow the club of Hercules, and the thunder of Jupiter, for the purpose of destroying a flea;" or of the modern mathematician, who, without any fable, or any figure of rhetoric, proposed to adjust a standard measure, by placing it at a distance, and viewing it with a good telescope. The habit of rely-

ing too confidently on calculation, and too little on common sense, will perhaps account for the mistakes of Lagrange, which have been already noticed, respecting the forms of columns, and the illumination of optical instruments: nor are they the only instances of the kind which may be produced from the modern history of the sciences. It seems, indeed, as if mathematical learning were the *euthanasia* of physical talent; and, unless Great Britain can succeed in stemming the torrent, and in checking the useless accumulation of weighty materials, the fabric of science will sink in a few ages under its own insupportable bulk. A splendid example has already been displayed by the author of the article *ATTRACTION* in this *Supplement*, and to do justice to our neighbours, it must be allowed, that they have received the boon with due gratitude, and acknowledged it by merited applause: "All the analytical difficulties of the problem," say Legendre and Delambre (*M. Inst.* 1812), "vanish at once before this method; and a theory, which before required the most abstruse analysis, may now be explained, in its whole extent, by considerations perfectly elementary." It is indeed only when a subject is so simplified, that the investigation can be considered as complete, since we are never so sure that we understand the process of nature, as when we can trace at once in our minds all the steps by which that process is conducted. It is not without some reason that a similar disposition, to revel in the luxury of mathematical sport, has been sometimes objected to Laplace, a man of equal analytical acquirements with Lagrange, but possessed apparently of greater sagacity, and certainly more successful in his application of mathematics to physical researches, although he, also, seems, on some occasions, to have suffered his habits of abstract reasoning to lead away his attention from the true conditions of the problem; particularly in his first supplement respecting capillary attraction, which concludes with an equation so erroneous, that he has been obliged to abandon it in silence. (See the article *COHESION*.) Another instance of ill applied computation has been noticed in the article *CHROMATICS*; when Laplace attempted to deduce the laws of extraordinary refraction from the principle of the minimum of action, he seems to have forgotten that the demonstration of that principle, in his own great work, rests expressly on a condition which is here wanting, that "the forces concerned must be functions of the distances," and of course independent of the directions. These imperfections, however, would not deserve to be noticed as materially affecting the general merits either of Lagrange or of Laplace, but they may be considered as accidents, which ought to warn us, against relying too implicitly on authority, however high, when it appears to militate against clear simple reasoning, and sound common sense.

Delambre, *Mém. Inst.* 1812, ii.—*Journal de l'Empire*, 28, Apr. 1813.—Virez et Potel *Précis Historique*, 4. Paris, 1813.—Cossali *Elogio*, 8. Padua, 1813.—Maurice in *Biographie Universelle*, XXIII. 8. Paris, 1819. (A. M.)

LALANDE (JOSEPH JEROME LE FRANÇAIS [de]), a most zealous and accomplished astronomer, born at Bourgen Bresse, 11th July 1732, was the son of

Lagrange
||
Lalande.

Lalande. Peter Lefrançois, and Marianne Mouchinet, his wife.

His parents were in easy circumstances, and his education being somewhat too indulgent, the natural quickness and impetuosity of his temper was too little restrained. His earliest taste, like that of most other children, seems to have been for romantic tales, and he was fond of making little stories with the materials that he possessed, but their subjects were chiefly religious. He was in the habit of living much with the Jesuits, and he imbibed from them a predilection for the pulpit; at the age of ten he used to amuse himself with making sermons, and preaching them to a select congregation. The comet of 1744, however, with its long tail, took more forcible possession of his imagination, and he watched it with the most unremitting attention. Having been sent to Lyons, to continue his studies under the Jesuits there, he acquired a taste for poetry and eloquence, and was then inclined to devote himself to literature and to the bar; but an eclipse of the sun recalled his attention to astronomy. His parents wished him to follow the profession of a magistrate, and sent him to Paris with that view; but he accidentally lodged in a hotel where Delisle had established an observatory, and this circumstance led him to become acquainted with that professor, and to attend his lectures. These lectures were by no means popular; and the want of a more numerous audience made it easy for the professor to accommodate his instructions to the fixed attention and rapid progress of his new pupil, who became singularly attached to his master, and to all the methods which he employed. Lalande attended, however, at the same time, the physico-mathematical lectures of Lemonnier, who was more in credit as a teacher, and who also took great pains for his improvement.

In the meantime he had completed his legal studies, and at the age of eighteen he was called to the bar as an advocate. His family was anxious for his return to Bourg; but just at that time Lemonnier obtained leave to nominate him as a substitute for himself on an astronomical mission to Berlin, where he was to make observations on the lunar parallax, corresponding with those which Lacaille was sent to the Cape to obtain. He was favourably received by Maupertuis, who introduced him to Frederic and his court; and was made a Member of the Academy of Sciences at Berlin, when he was about nineteen.

He remained a year in that city, observing at night, and passing his mornings in the study of the integral calculus, under Euler's direction; and his evenings in the society of Voltaire, Maupertuis, D'Argens, and other men of talents. It was not likely that the intercourse with such persons should confirm the principles which he had imbibed from the Jesuits; his moral conduct, however, does not appear to have been influenced by his change of sentiments. After his return to Bourg, he pleaded a few causes to oblige his friends; but the success of his operations at Berlin obtained him speedily a place in the Academy of Sciences at Paris; for, in 1753, before he was twenty-one, he was chosen to

fill up a vacancy in the department of astronomy, which had been open for some years. He soon after offended his friend Lemonnier, by rejecting too harshly an unfounded objection of that astronomer to his method of computing the effect of the earth's ellipticity on the lunar parallax, which differed from Euler's formula. Lacaille, who drew up the report of a committee appointed on the occasion, decided in Lalande's favour; but Lemonnier remained dissatisfied, and would not see him for twenty years. He had some similar discussions, at a later period, with Dusejour, who was a little too severe in criticizing some of his approximations, as if they had been intended to be rigidly accurate; but their personal friendship remained unaltered.

For more than fifty years he continued to be a constant and voluminous contributor to the *Memoirs* of the Parisian Academy, as well as to other scientific collections. His investigations were always judiciously directed to the advancement of astronomy; but they can scarcely ever be said to have exhibited any marked features of talent, or of address, beyond what might be expected from the industry of a man of good ordinary abilities, confining himself almost entirely to one subject. He was always anxious to call the public attention to astronomy as a science, and to himself as an individual. Thus, on occasion of the transits of Venus in 1761 and 1769, he addressed a circular letter to most of the governments of Europe, on the importance of obtaining a multiplicity of collateral observations, and he received in reply several invitations, from sovereigns whose countries were more favourably situated for the purpose than France, to come and make the observations in person. He thought it, however, unnecessary to leave Paris on the occasion; he contented himself with being the first to announce to the public the result of the most satisfactory comparisons; and his countrymen seemed to give him almost the whole credit of every thing that had been done by others, in conformity with his suggestions. He was much mortified, however, in not receiving from Father Hell an account of the observations made at Wardhus: and he was afterwards greatly inclined to dispute their accuracy, because Hell made the parallax smaller than he did by $\frac{1}{2}$ of a second: while the mean of both results, which is 8, 6'', agrees extremely well with the most modern computations: but, in the end, he did justice to the importance of Hell's observations.

He was constantly in the habit of passing a few months every year with his family in the country, and he occasionally amused himself, in the course of these visits, with mineralogical excursions, and with chemical studies. He delivered, about the year 1758, an oration, before a public assembly at Lyons, on the advantage of monarchy above every other form of government; he even adhered to a similar opinion, and expressed it openly, in times when nothing but his celebrity, as a man devoted exclusively to science, could have made it safe for him to declare it.

After having published the Astronomical Tables of Halley, he felt the necessity of a new collection, and determined to begin with those of Mercury, which he found the most imperfect. He pursued, for this

Lalande.

purpose, a regular course of observations at the Palais Royal, where he used to go before sunrise, in the winter mornings, to see the planet in the twilight. Having occasion to refer to the observations recorded by Ptolemy, he found it necessary to refresh his acquaintance with the Greek language, which he had in some measure neglected. But, with all his labour and diligence, his tables of Mercury exhibited, in 1786, an error of 40 minutes in the time of a transit: the circumstance mortified him extremely; but it led to a revision of the tables, and he afterwards succeeded in making them much more perfect. It must be recollected, that, in the time of Hevelius, a transit was anxiously expected for four whole days before it occurred.

He next undertook to improve the tables of Mars and Venus: his tables of these planets were, on the whole, less accurate than those of Mercury, though more exempt from great occasional errors. He had computed their perturbations in the *Memoirs* of the Academy; but he never thought it worth while to compare his formulas with observation. The irregularities of Jupiter and Saturn were much more discouraging; he was obliged to confine himself, in discussing them, to the most modern observations; and he did not appear sufficiently to appreciate the empirical equations of Lambert, though they greatly diminished the errors of Halley's tables.

When Maraldi had given up the management of the *Connaissance des Temps*, Lalande and Pingré were candidates for the appointment. Lalande succeeded in obtaining it; but he had the modesty to confess that the work would have been more accurately performed by Pingré, if his connexion with the church had not, according to the rules of the Academy, incapacitated him for the situation. He made the work, however, much more popular, as a miscellaneous publication, than Pingré was likely to have done; and he was less prejudiced than Pingré in the choice of his tables. He remained editor of the work from 1760 to 1775; it was conducted by Jeaurat from 1776 to 1787, and from 1788 to 1793 by Méchain: Lalande then undertook it once more; Méchain being engaged in some measurements with Delambre, the Academy having been abolished, and its members dispersed.

Lalande had been disposed to call in question the assertion of Newton and of Voltaire, that no comet could possibly come into contact with the earth; and he had proved that the effect of perturbations at least rendered their reasonings somewhat inconclusive. A short memoir on the subject, which was to have been read at a public sitting of the Academy, was accidentally omitted, as not very important, from the pressure of other business. This circumstance alarmed the sensibility of the public of Paris, who fancied that Lalande had foretold some dreadful catastrophe, which the Government was afraid to announce; and when the memoir was published, they insisted that its contents had been modified, to lessen the alarm. Dusséjour made some objections to the author's reasoning: but the whole affair was soon forgotten.

A memoir on the length of the year was honour-

ed with a prize by the Academy at Copenhagen. Delambre, however, thinks the determination not so good as the earlier one of Lacaille, though much better than Mayer's, which was more commonly adopted. Lalande took great pains also with the subject of the sun's rotation, employing in his computations of the places of the spots an easy approximation, instead of Dusséjour's more laborious methods; but being careful to compare with each other the most distant observations of the same spot. From the existence of this rotation he thought it reasonable to infer that the sun had also most probably a progressive motion, which would naturally be produced by any single impulse capable of occasioning a rotation. He had some discussions with Dr Maskelyne, respecting the mode of computing the equation of time, in which Maskelyne appears to have had the advantage.

In the year 1762, Delisle resigned in his favour the Professorship of Astronomy in the College de France, which he kept for nearly 40 years. He allowed the most attentive of his pupils to board with him at a cheap rate, doing his utmost on all occasions to promote their success in their studies and in life. Thus he brought forwards Méchain and Dagelet, and afterwards his own nephew, who completed, with so much diligence and accuracy, the *Description of the Heavens*, which he had himself projected, and which had been begun by Dagelet before his unfortunate expedition. He was made a Fellow of the Royal Society of London in 1763.

His health was generally good, though his constitution was delicate. He had an attack of jaundice in 1767, which was attributed to intense application; but he completely recovered from its effects by an attention to diet, and by the use of horse exercise. He then intended to leave all his property to the Academy; but he afterwards gave up his family estates to his relations, and lived on his appointments only, refraining from all kinds of luxuries, in order to be the more able to do acts of liberality to his friends, whom he always sought to oblige in the most delicate manner, and often without making his services known. He had a pension from Russia in the time of the Empress Catherine; it was suspended by Paul, but restored in 1805 by Alexander.

He was not particularly successful as an observer, but used to refer to the works of his contemporaries, Bradley and Lacaille, though not exactly according to the expression of one of his biographers, "as Ptolemy had done to those of Hipparchus;" for Hipparchus must have been dead two centuries before Ptolemy was born. On the occasion of the disappearance of the ring of Saturn in 1774, he went to Béziers, in order to profit by the superior serenity of the air there, the climate of that country being supposed to be the best in France; but his observations were less valuable than others made at Paris and in London.

In the year 1798, he undertook an astronomical expedition to Gotha. He had once meditated an aerostatical voyage there; but his companion took care that their dangers should terminate in the Bois de Boulogne. He was received with much interest

Lalande.

Lalande. at Gotha by an assembly of astronomers, that was collected from different parts of Germany. The object of the congress was perhaps not unmixed with personal vanity; but it had no political design to promote, unless the general adoption of the new French measures could be considered as a political object. Lalande was by no means a revolutionist: he was sufficiently free from any prejudices of education; but he openly condemned the political opinions of the day; and, in 1792, he even exposed himself to great personal danger, in order to save the life of Dupont de Nemour, after the 10th August; and he was equally useful to some of the clergy, whom he concealed in the buildings of the Observatory at the College Mazarin, making them pass for astronomers. He had also the courage to publish accounts of Lavoisier and Bailly a short time after their deaths.

The attentions of the German astronomers gave him sincere pleasure. He was at all times extremely sensible to compliments, and even to flattery, though very regardless of satire. He used to call himself a sponge for praise, and an oil-cloth for censure. He professedly believed himself endowed with all the virtues, modesty not excepted. He was so fond of notoriety, that he once undertook to exhibit the variations of the light of Algol to the public of Paris on the Pont Neuf; but the police interfered, thinking it right to prevent a disorderly assemblage.

Though Lalande can only be classed in the second rank as an inventive astronomer, or a mathematician, he certainly stands in the first as a professor and a popular writer. His methods of calculation have in most instances been already superseded by others more convenient or more exact; those which related to particular phenomena for want of sufficient precision, and those which were more general for want of being readily applicable, without continual repetition, to a sufficient number of concurring observations. It has been observed, that he may perhaps have been often too zealous in the pursuit of his favourite objects; but that, if he had possessed more circumspection, and less vivacity of character, he would have been more exempt from criticism, but he would have rendered less important services to science and to mankind.

His last illness was of a consumptive nature, and he seems to have accelerated its termination by attempting too much to harden himself. He died 4th April 1807, nearly 75 years old, and in the perfect possession of his faculties. His last words, when he dismissed his attendants to rest, were, "I have need of nothing more," and in a few minutes he was dead. Had he survived a few hours, he would have received a letter from Dr Olbers, announcing the discovery of a new planet; for which that distinguished astronomer afterwards received the fourth prize medal upon the institution founded by Lalande in 1802, for the most important astronomical discovery made in the course of the year.

Of his voluminous and diversified publications a simple enumeration of the subjects will perhaps be thought too long for perusal, though not improper for inser-

tion in a work, which ought to comprehend a complete literary history or bibliography of the sciences.

1. We find, in the *Memoirs of the Parisian Academy of Sciences for 1751*, an account of his *Observations at Berlin*; which also appears in the *Memoirs of Berlin for 1749*; and a Latin translation in the *Acta Eruditorum for August 1752*. 2, 3. 1752-53. *An Essay on the Lunar Parallax*. 4. 1754. *A transit of Mercury*. 5. *Elements of Mars*. 6. 1755. *Longitude of Berlin*. 7. *Lunar Eclipse*. 8. 1756. *Transit of Mercury*. 9. *Lunar parallax continued*. 10. 1757. *Observations at the Luxembourg*. 11. *Transit of Venus*. 12. *Secular equations and mean motions*. 13. *A gnomonical problem*. 14. *Meridian altitudes*. 15. 1758. *Perturbations of Mars by Jupiter*. 16. *Motions of the planetary nodes*. 17. *Change of latitudes of the stars*. 18. 1759. *Comet of 1682 and 1759*. 19. 1760. *Sun's diameter*. 20. *Perturbation of Venus by the earth*. 21. *Eclipse of 1760*. 22. 1761. *Solar parallax*. 23. *Interpolation*. 24. *Transit of Venus observed*. 25. *Solar parallax*. 26. *Transit computed*. 27. *Observed at Tobolsk*. 28. *In Denmark*. 29. *Compasses, and the variation*. 30. *Perturbation of Mars by the earth*. 31. *Planetary nodes*. 32. 1762. *Equation of time*. 33. *Obliquity of the ecliptic*. 34. *Hourly motion in transits*. 35. *Nodes of Jupiter's satellites*. 36. *Diameter of Venus*. 37. *Comet of 1762*. 38. 1763. *Eclipses of Jupiter's satellites*. 39. *Solar eclipses for a spheroid*. 40. *Triangles, rectilinear and spherical*. 41. 1764. *Transit of 1769*. 42. *Lunar libration*. 43. 1765. *Motion of Saturn*. 44. *Eclipses of Jupiter's satellites*. 45. *The third satellite*. 46, 47. 1766. *Theory of Mercury*. 50. 1768. *Opposition of Jupiter*. 51. *Transit of 1769*. 52. *Orbit of Saturn*. 53. 1769. *Lunar observations*. 54. *Comet of 1769*. 55. *Transit of Venus*. 56. *A solar eclipse*. 57. *Transit of Venus*. 58, 59, 60. *Comparisons of observations*. 61. 1779. *Solar parallax*. 62. *Sun's diameter*. 63. *Appearances in the transit*. 64. *Chappe's observation*. 65. 1771. *Theory of Mercury*. 66. *Astronomical observations*. 67. *Solar parallax*. 68. 1772. *Transit of Venus*. 69. *Tides*. 70. 1773. *Comets*. 71. *Saturn's ring*. 72. 1774. *An opposition of Saturn*. 73. *Saturn's ring*. 74. *Disappearance of the ring, at Begiers*. 75. 1775. *Opposition of Mars*. 76. *Elements of Mars*. 77. *Same latitudes and longitudes*. 78. *Opposition of Jupiter and Saturn*. 79. *An eclipse of Saturn*. 80. 1776. *Spots and rotation of the sun*. 81. 1777. *Observations at Paris and Madrid*. 82. *An observation of Mercury*. 83. *Longitude of Padua*. 84. *The solar spots, continued*. 85. 1779. *Third satellite of Jupiter*. 86. *Theory of Venus*. 87. *Herschel*. 88. 1780. *Obliquity of the ecliptic*. 89. *Precession of the equinoxes*. 90. *Fourth satellite of Jupiter*. 91. 1782. *Duration of the year*. 92. *A transit of Mercury*. 93. 1783. *An eclipse of the sun*. 94. *Inclination of the orbits*. 95. 1784. *Elements of Jupiter*. 96. *Ellipticity of the earth*. 97. 1785. *Motion of Venus*. 98. 1786. *Secular equations of the sun and moon*. 99. *Mass of Venus*. 100. *Equation of Mars*. 101. *Mars in quadrature*. 102. *Orbit of Saturn*. 103. *Theory of*

Lalande.

Lalande. *Mercury, fifth memoir.* 104. *Satellites of Jupiter.* 105. *Fifth of Saturn.* 106. 1787. *Ferne's measurement.* 107. *Herschel's.* 108. *Jupiter's third satellite.* 109. *Conjunction of Venus.* 110. *Motion of Saturn.* 111. *Inclination of Saturn.* 112. *Answer to Lemoigner, on lunar observations.* 113. *Solar eclipses of 1787.* 114. *Eclipse of 1666.* 115. *Caspian sea.* 116. 1787. *Eclipse of 1765.* 117. 1788. *Eclipses applied to longitudes.* 118. *Conjunction of Venus.* 119. *Lunar parallax, fourth memoir.* 120. *Moon's diameter.* 121. *Jupiter's fourth satellite.* 122. *Satellites of Saturn.* 123. *Light of Algol.* 124. *Height of the Seine.* 125. 1789. *Impact.* 126. *Observations of 8000 stars, first part.* 127. *Motion of Venus.* 128. *Astronomical observations.* 129. *Observation of Mercury.* 130. *Tides.* 131. *Catalogue of stars, second part.* 132. 1790. *Disappearance of Saturn's ring.* 133. *Interior of Africa.* 134. *Mém. Inst. I.* 1798. *Orbit of Mercury.* 135. *II.* 1797. *Ocullations of Aldebaran.* 136. *Solar eclipse of 1706.* 137. *Solar eclipse of 1748.* 138. *V.* 1803. *Zodiac at Strasbourg.* 139. *Eclipses calculated.* 140. *Opposition of Mars.* 141, 142. *Motion of Venus.* 143. *Motion of Mercury.* 144. *VI.* 1806. *A transit of Mercury.*

145. The earliest of his separate publications appear to have been two little volumes, intended for provincial circulation only, entitled *Etrennes Historiques*, 24. Par. 1755-6. 146. Another little article of his miscellaneous works was a *Discours qui a remporté le prix de l'Académie de Marseille*, en 1757. *Mars.* 1757. The subject was the spirit of justice, as tending to the glory and the stability of a government. 147. We have then *Three letters on platina.* *Journ. des Sav.* 1758. Jan. Jun. 1760. Feb. 148. *Letter on a new sun dial.* *Journ. Sav.* Jun. 1758. ii. 139. The lines being invisible when the sun does not shine.

149. *Tables astronomiques de Halley*, 2 v. 8. Paris, 1759. Containing several new tables, and an elaborate history of the comet of 1759, of which the author had computed the perturbations, according to the theory of Clairaut. 150. *Congissance des tems*, 16 vols. 8vo. Par. 1760-1775. 15 vol. 1794-1807. This work contains, besides, the *Ephemeris*, an important selection of the most useful astronomical papers. On one occasion, for temporary reasons, these papers were published in a separate volume. 151. *Exposition du calcul astronomique.* 8. Paris, 1762. A companion to the almanac.

152. *Oraison funèbre de Maurice Comte de Saxe*, 8. Par. 1760. 153. *Art du Papetier*, f. Par. 1761. 154. *Pancheminier*, 1762. 155. *Cartonnier*, 1764. 156. *Chamoiseur*, 1764. 157. *Tanneur*, 1764. 158. *Mégissier*, 1765. 159. *Maroquinier*, 1766. 160. *Hengroyeur*, 1766. 161. *Corroyeur*, 1767.

163. *Letter on Delisle's calculations*, *Journ. Sav.* Apr. 1761. 164-5. In the 54d volume of the *Philosophical Transactions* for 1761 and 1762, we find several papers of Lalande; two *On the transit of Venus*; 166. one *On Norwood's measurement of the earth*; 167. *An Account of a comet*; and, 168. *An account of ocullations of the fixed stars by the moon.* 169. In the *Transactions* for 1769, another paper on the transit of Venus.

VOL. V. PART II.

170. *Discours sur la douceur*, 1763. This essay was intended as a sort of exercise for the author's own moral improvement; and he made it a rule to read it over and over every year, in order to assist him in commanding his temper. He may possibly have derived some little advantage from the practice, but he never acquired enough of self-command to refrain from wounding the feelings of another, by any pointed remark that might suddenly occur to him.

171. *Astronomie*, 2 v. 4. Paris, 1764. 3 v. 1771, 1792, Vol. IV. 1780, not reprinted. This compilation far excelled, in utility, all former works of the kind, and will always be considered as exhibiting the most perfect picture of the science, such as it existed from 1760 to 1790, with all the details of practice and computation. Lemoigner called it, with some truth, the great newspaper of astronomy. The *Treatise on the Tides*, which constitutes the fourth volume, is chiefly a collection of observations, not sufficient even for the basis of a complete theory: an abstract of it may be found in the *Mém. Acad. Dijon*, II. 1774. 172. *Figure du passage de Venus de 1769*, Paris, 1764. Together with an explanatory memoir. 173. *On the equation of time. Recueil pour les astronomes*, 1765.

174. He undertook the mathematical department of the *Journal des Savans*, from 1766. 175. *On the coins of Piedmont*, *Journ. Sav.* Dec. 1767. 176. *Voyage d'un François en Italie*, 8 vol. 12. A correct guide and faithful repertory for travellers, containing some scientific information, besides maps of the principal cities. 177. *Dissertation sur la cause de l'élévation des liqueurs dans les tubes capillaires*, 8. Par. 1770. 178. *A dictionary of astronomy*, in the *Encyclopédie d'Yverdun*, 56 v. 4. 1770-6. 179. *Abégé d'astronomie*, 8. Par. 1773, 1795, translated into various languages. 180. *Notes on the Mondes of Fontenelle*, 24, Paris, often reprinted. 181. *Notes on Bouguer's Traité de Navigation.* 182. *Mémoire sur le passage de Venus*, 4. Par. 1773, with a life of Dr Bevis. 183. *Réflexions sur les comètes qui peuvent approches de la terre*, 8. Par. 1773. 184. *Lettre à Cassini sur l'anneau de Saturne*, 8. Toulouse, 1773; a violent attack, which was speedily suppressed by the author. 185. *Ephemerides*, 3 vol. VII. VIII. IX. Paris, 1774, 1792. This was a continuation of Lacaille's computations, containing also some detached articles of importance; for instance, *Hampstead's catalogue*, in the eighth volume. 186. *A celestial 12-inch globe*. Paris, 1775.

187. The *Astronomical articles* in the *Supplement* of the *Old Encyclopédie*, about 1776: those of Dalember, in the body of the work, having been little more than extracts from Lemoigner. 188. To the *Encyclopédie Méthodique* Lalande contributed a *Dictionary of Astronomy*, making about one-third of the *Mathématiques*, 3 vol. 4to. They were principally extracted from his own astronomy; and the article *Cadran*, which is very elaborate, was originally intended for a fifth volume of that work.

189. *Traité des canaux de navigation*, f. Paris, 1778. This volume is principally descriptive, and especially of the canal of Langnedoc. 190. *Letter on the variation of the compass, as connected with the temperature of the earth*, *Journ. Sav.* 1780. Sept.

Lalande
||
Lambert.

191. *L'opéra d'Astronomie de Lacaille*, 8. Par. 1780. With some Notes. 192. *Astronomie, in Bibliothèque des Dames*, 12. Par. 1786, 1796.

193. Letter on the name of the planet Herschel, Journ. Sav. 1789. Objecting to "Uranus." 194. *Description d'une machine de M. Ramsden*, 4. Paris, 1790. The dividing engine, translated. 195. Account of nine Lalandes, Journ. Sav. Nov. 1791. 196. Journey to Mannheim in 1791. Journ. Sav. 1791. 197. On the zodiac at Strasburg, Journ. Sav. 1791.

198. *Abrégé de Navigation*, 4. Paris, 1793. With a full catalogue of works relating to the subject, and many useful tables. 199. *A Journey to Mont Blanc*, performed in 1796. *Mag. Encycl.* II. iv. 483. 200. *Histoire Céléste Française*, I. 4. Par. 1801. Containing the catalogue of stars begun by Dagelet, and continued by Michel Lefrançois Lalande, the nephew of the editor. 201. Continuation of Montucla's *Histoire des Mathématiques*, 2 v. 4. Par. 1802; making the third and fourth of that elaborate work, but not equally well digested and discussed with the original part. 202. *Tables de Logarithmes*, 18. Par. 1802. 203. Four memoirs on Ceres, Journ. Phys. 1802. 204. Some articles in the *Nurologie des hommes célèbres*. He wrote, at different times, accounts of the lives of Vieq d'Azyr, Delisle, Commerson, Ferron, Me. Lepaute, and Dubocage; and he had undertaken a life of Bucholz, a short time before he died: Commerson had complimented him by making a genus Lalandia, transgressing in his favour the classical canon of the Botanists, to reserve such honours for the reward of merit in their own department.

205. *Bibliographie Astronomique*, 4. Paris, 1803. With a history of the Progress of Astronomy from 1781 to 1802. This useful volume was printed at the public expence, under the auspices of François de Neufchateau. The author possessed a very extensive collection of astronomical books, and it has been regretted that he did not insert a more complete account of some of the most rare; but the work is already sufficiently voluminous. Some other productions are attributed to him in the *Dictionnaire des Anonymes*; but they would probably have added little to his fame, had they been acknowledged.

(Delambre, *Mém. Inst.* VIII. 1807. H. P. 30, and *Biographie Universelle*, XXIII. 8. Paris, 1819. Ma. C. de Salin, *Magaz. Encycl.* 1810, ii. P. 288; including a sketch by himself, written in 1804.)

(E. x.)

LAMBERT (JOHN HENRY), a natural and moral philosopher of great talent and originality, born 29th August 1728, at Mulhausen in Upper Alsace, was the son of a French refugee in a very humble station, and one of a numerous family.

His early studies were only assisted by the instruction he obtained at a small free school in his native town. His father, who was a tailor, could scarcely even afford him leisure from mechanical labour; he was obliged to read and write in the night, and in order to procure candles, he made little drawings for sale, while he was watching the cradle of his infant sisters. Having learned to write a good hand, he obtained some employment as a

copying clerk in the chancery of the town, which Lambert he gave up, when he was only 15, upon being appointed book-keeper at some iron-works in the neighbourhood. At 17, he became secretary to a Doctor Iselin, who was the editor of a newspaper at Bâle, and who became his firm friend through life. He had now time to render himself familiar with the works of Wolf, Locke, and Malebranche, to which he was in a great measure indebted for the correct logical method that he ever after followed in his researches; having, however, confirmed and improved it by the study of the mathematics, to which he devoted himself with great zeal, and which, after all, constitutes the best practical school of genuine logic.

In 1748, he removed to Coire, having been recommended by Iselin, as private tutor to the family of the President Count Peter de Salis, whom he undertook to instruct in history and religion, as well as in languages and science. The library of his patron was extensive; he profited by it in all its departments; and his residence at the house of an accomplished statesman, frequented, as it was, by the best informed persons of different countries and with different pursuits, could not but greatly contribute to the extension of his knowledge, and the unimprovement of his taste. He even amused himself with some poetical exercises in various languages, which must, at least, have been of advantage to his style in prose. He felt the importance of his literary and scientific pursuits to himself and to the world, and in 1752, he determined to keep a journal of all his studies, which he continued throughout his life; he began to publish a variety of fugitive pieces, on different subjects, in the newspapers and in other periodical works of the day, some of which attracted the notice of his learned countrymen, and, in 1754, he was made a member of the Physico-medical Society, then lately established at Bâle, to the Transactions of which he contributed many interesting papers. In 1756 he went to Gottingen with two of his pupils, and in 1757 to Utrecht. The next year the party returned to Coire, by way of Paris, Marseilles, and Turin. At Paris he paid a visit to D'Alembert, who does not appear at that time to have appreciated his merit very highly, though he afterwards rendered him some services with the King of Prussia; but he became more intimately acquainted with Messier the astronomer.

In 1759 he quitted the family of the Count de Salis, and went to settle at Augsburg, having a small salary as a member of the Electoral Academy of Bavaria. From 1761 to 1763 he was again at Coire and in its neighbourhood, being employed in fixing the boundaries between the country of the Grisons and the Milanese territory. Towards the end of 1763, having had some disputes with the Bavarian academicians, he went to Leipzig, and the next year to Berlin, where he was made a member of the Royal Academy of Sciences, and where he continued to reside during the remainder of his life, receiving many marks of favour from the discriminating liberality of Frederic; thus, in the year 1770, he was made superior counsellor of the Board of Works, with an additional salary. He contributed a num-

Lambert. ber of valuable memoirs to the collection of the Academy, and in 1774 he undertook the direction of the *Astronomical Almanac*, for which he was admirably qualified. He was also a constant writer in the journal published by Nicolai, under the title of the *Universal German Library*; and he kept up a very extensive correspondence on various subjects of literature and science.

He was regularly in the habit of writing or reading from five in the morning till twelve; and again from two till midnight; a degree of application unquestionably far beyond that which would have been best calculated for producing the maximum of valuable effect.—Perhaps, if he was paid for writing by the ream, he may have earned as much from the booksellers as he would have done by a more judicious economy of his powers; but a nervous system, attenuated by the daily study of 17 hours, could never have been capable of being employed in any very elevated flights of genius, or in the invention of any sublime or exquisite novelties either in science or in literature: and it is only wonderful that he did any thing so well, as almost to form an exception to this general remark. He was indeed supposed to have injured his health by continued application, and he died consumptive at 49, the 25th September 1777. He had never been married. His person was of the middle size, with an interesting and expressive countenance; he was animated and lively in conversation, and liked discussion, but not disputation. He had no literary quarrels; and his criticisms were not offensive, even when they ceased to be flattering. His morals were strictly correct, but his manners were not altogether in unison with those of the society to which his talents had elevated him: he is said to have been timid, awkward, slovenly, and fond of low company; but upright, patient, unostentatious, and compassionate; essentially modest, but as ready to assert his own merits, as to admit his defects. He had a happy facility in managing the instruments of computation, especially in the arrangement of converging series; and he had a peculiar talent for expressing the results of observation by an analytical formula; having first thrown them into the form of a geometrical diagram to assist his invention; a process which he employed with regard to the probabilities of life in London; and to the inequalities of Jupiter and Saturn. In short, after Euler, Lagrange, D'Alembert, and Daniel Bernoulli, there are few mathematicians and natural philosophers of any age who can be put in competition with him, and still fewer who benefited the public by so many diversified labours.

It would be hopeless to attempt to pursue his indefatigable pen through all its wanderings; and a complete catalogue of his works would be as useless as it is unattainable. A man who wrote so incessantly must have written many things which were destined to oblivion from their first production. It will be sufficient to mention the most remarkable of his works, without any very strict regard to the priority of their publication.

1. In the *Acta Helveticae of the Society of Bâle*, 11. 1752, we find an *Essay on the force and measurement of heat*, a subject which the author resumed in the

latter part of his life. 2. *A general series*, somewhat resembling Taylor's. *Act. Helv.* 111. 1758. 3. *Metéorological observations*. *Ibid.* 4. He also published a paper *On the vibration of chords* in the same collection.

5. *Les propriétés les plus remarquables de la route de la lumière par les airs, et en général par plusieurs milieux réfringents*. 8. Hague, 1759. German by Tempelhof. Berl. 1773. This work does credit to the ingenuity and mathematical abilities of the author, though its results may be obtained in a simpler manner by some methods more recently invented.

6. *La perspective libre*. 8. Zurich, 1759. Another edition, in German. The second German edition, 2 v. 8. Zurich, 1773, contains some additional matter, especially a system of geometry, depending, as it is said, upon the ruler alone, without any other instrument. Such a system must, however, have been extremely limited in its application, much more so than Mascheroni's *Geometria del Compasso*.

7. *Photometria, sive de mensura et gradibus luminis colorum et umbræ*. 8. Augsb. 1760. This original and interesting volume includes and surpasses the greater part of Bouguer's experimental determinations. It contains the important discovery that a luminous surface emits its light with equal intensity in all directions; together with some improvements in the theory of twilight, and an investigation of the comparative light of the sun and moon, and stars and planets.

8. *Insigniores orbitæ cometarum proprietates*. 8. Augsb. 1761. We here find the elegant theorem for expressing the relation of the area of a sector to the sides of the triangle inscribed in it. This theorem had been demonstrated with respect to the parabola by Euler, in 1740; but Lambert first extended it to the other conic sections; and he certainly reinvented the whole, without being aware of what Euler had done. It may be found, together with a concise demonstration, and a further account of this work, in the translation of Olbers's *Essay on Comets*, which has lately been published in the *Journal of the Royal Institution*.

9. *Cosmologische Briefe*. 8. Augsb. 1761. A French translation of these *Letters on the Universe* appeared in the *Journal Helvétique of Neuchâtel*, 1763-4; an extract was published by Merian, with the title of *Système du Monde*. 8. Bouillon, 1770; Berlin, 1784; and a translation by Darquier appeared at Amsterdam, 8. 1801. The whole work is written in a popular style, and adapted to the taste of general readers. The author's favourite idea was to make the sun a sort of planet, revolving round some other great body; and he supports the opinion by an argument derived from the supposed insufficiency of the laws of gravity, as relating to the solar system, for explaining some of the inequalities of the motion of Jupiter and Saturn, which have, however, since been reduced to the general analogy by Lagrange and Laplace.

10. *Zusätze zum traité de nivellement Von Picard*, 12th August 1761, explaining some improvements on Picard's level, executed by Brander, an ingenious artist whom Lambert also assisted in the improvement of Gunter's sliding rule. 11. He published an

32. *Remarks on the velocity of sound.* M. A. Berl. 1765; an unsuccessful attempt to reconcile the theory with observation; it was reserved for Laplace, by a single happy suggestion, to remove the whole difficulty. 33. *On pneumatics, as applied to painting.* Ibid. 34. *Trigonometrical observations.* Ibid.

35. *De Topici Schediasma*, 1768. 36. *Remarks on the divisors of numbers.* Nov. Act. Erid. 1769. 37. *Anmerkungen über des Branderschen micrometers.* Augsb. 1769. Branders micrometers were of glass. 38. *Experiments on Hygrometry.* M. Acad. Berl. 1769; relating to evaporation, and to the indications of hygrometers, especially those of catgut. 39. *Supplementa tabularum logarithmicarum*, 8 Berl. 1770. With a valuable introduction in German, on the abridgment of computations. 40. *Anmerkungen über die kraft des Schiesspulvers*, 8 Berl. 1770. In this investigation of the force of fired gunpowder, the author attacks several points in the theory of Robins, published a few years before.

41. *Hygrometric*, 4. Augsb. 1770. 42. *On directors for the light of lamps.* M. Acad. Berl. 1770. 43. *On ink and paper.* Ibid. 44. *Analytical observations.* Ibid. relating to the general theorem resembling Taylor's, which was further discussed by Euler, and modified by Lagrange. 45. *On Taxometry, or the measurement of order.* Ibid. considered as comparable in degree; and expressible by numbers. 46. *Architectonik*, 2 v. 8. Riga, 1771. A logical and metaphysical treatise on the most simple basis of philosophical and mathematical knowledge, written in 1763. The last part, which relates to magnitude, is the most approved; but the whole work was never much read, being partly superseded by the more ostentatious novelties of the day. 47. In the *Berlin Memoirs* for 1771, we find papers on Meteorology. 48. *On the atmospheric influence of the moon.* 49. *On achromatic telescopes of one kind of glass only.* 50. *On the apparent paths of comets.* 51. *On the grounds of superstitious belief, as compared with probability.* 52. *Ueber das Farbenpyramide*, 8. Berl. 1772. A description of a pyramid of wax, intended for the illustration of all the possible varieties of combination of the primitive colours. 53. *Astronomisches Jahrbuch*, 8. Berl. 1774-9. An accurate and extensive ephemeris, with many original communications annexed to it. 54. In the M. A. Berl. 1772, a paper *On Friction* supposed to follow the law of the resistance of fluids, with some remarks on that resistance. The opinion of the uniformity of the force of friction, which was even at that time general, was somewhat too hastily rejected by the author: but his computations may still be of use in some cases. 55. *On the fluidity of sand as resisting motion.* 56. *On hygrometry continued.* 57. *On the density of the air*, with respect to sound and to refraction. 58. *M. A. Berl. 1778 A Ballistic scale*: for determining the paths of projectiles in the atmosphere. 59. *Physical observations*, relating to Meteorology and to Optics. 60. *On the satellite of Venus*: at-

LAMP, is a name applied to various contrivances for furnishing artificial light. We shall, in addition to what is said under this head in the *Encyclopædia*, offer some remarks on the various kinds of Lamps for ordinary purposes, on Lamps for Light-Houses, on Lamps for Streets, and on the Safety Lamp.

Substances
used for
burning

Lamps are usually fed by expressed oils from vegetable or animal substances. In Britain, whale oil, boiled from the subcuticular fat of the whale, is used for common lamps.

Tallow is one of the most common substances employed for giving light. The spermaceti, which is found near the nervous substance of the spinal marrow in a particular kind of whale, is also used. There is a substance resembling spermaceti, formed by the decomposition of the muscular flesh of animals in moist places, which has been employed. Bees-wax, a vegetable substance collected by the bee, and which, in some of its qualities, resembles the essential oils, is one of the best materials for giving light.

In no region of the globe are human beings found

to exist without a supply of oil derived from animals or from vegetables; and in the more fertile regions several different plants, peculiar to each region, are cultivated on account of the fixed oil which is extracted from their seeds for use. These oils vary in quality. The oils fit to be employed in food are the most valued. Of the rest many have the qualities which fit them for burning in lamps.

At Paris, oil of rape-seed, and oil of poppy-seed, are clarified for the lamp by filtering through cotton, wool, and other processes. In the south of France and Italy the inferior kind of olive oil is used in lamps, and sometimes the oil of the plant called *Arachis hypogæa*, or earth-nut. In Italy, lamp oil has been pressed from the stones of the grape. In Piemont, walnut oil is used for lamps. On the eastern and south coasts of the Mediterranean, and in China, the inferior kind of oil of sesamum. In tropical countries, cocoa-nut oil, which, in the temperature of heat of Britain, is solid and white like tallow. It is burnt in lamps made of the shell of the cocoa-nut, and of bamboo. Much of the oil used in China is obtained by expression from the seeds of the tree called by botanists *Camellia oleifera*, which is extensively cultivated for that purpose; as is the shrub called *Croton sebiferum*, for the solid oil or tallow that the Chinese press from its fruit. Essential oils, extracted from plants by distillation, are too volatile, and, in consequence of their volatility, are too easily inflamed.

Petroleum and naphtha issue from the earth in several places, and these sources are generally in secondary strata, and originate from fossil vegetable matter in a state approaching to that of pit-coal. A source of petroleum existed some years ago near Colbrook Dale, and at St Catherine's near Edinburgh. The greatest natural deposits of petroleum and bitumen are in the Island of Trinidad, and in the Dead Sea in Judea. Naphtha is the most liquid of the oils proceeding from fossil vegetable matter, and possesses qualities very fit for burning in lamps. It is employed for this purpose at Genoa, where the streets are lighted with naphtha from Amiano in the adjacent territory. Naphtha, obtained in the state of a clear colourless liquid, by distillation from pit-coal, has of late been employed for burning, in street lamps, in London.

Alcohol or spirit of wine, being more clean than oil, is convenient for feeding a lamp that serves to heat a liquid in a small vessel; but the flame is blue, and therefore is not suitable for giving light.

In a spirit lamp, the surface of the spirit must be covered to exclude the air, for the spirit would catch fire if its surface were exposed.

Sulfuric ether is too easily inflamed, and too costly to be used for feeding lamps.

In a lamp, for the purpose of giving light without a considerable quantity of heat, it is required that only a small portion of the oil shall be inflamed at once; therefore, by means of the wick, a small portion of oil, minutely divided so as to expose a large surface, is subjected to the action of the heat. The heat decomposes the oil, and the gas resulting from the decomposition is burnt by the atmospheric air which surrounds the wick. In the gas lights, which,

The Wick

Lamps.

within the last few years, have come into use in many manufactories and cities in Britain, the operations of producing the gas and inflaming it, which take place at one time in the wick of a lamp, are performed separately. The gas is obtained from pit-coal, oil, or wood, but best from pit-coal or from oil, by heating these substances strongly in a retort; and when extricated, is conveyed away in pipes to the place where it is to be inflamed. The capillary attraction of the filaments of the cotton which compose the wick, raises up a small portion of oil into a situation where it may be exposed to the degree of heat necessary for producing flame.

In lamps of the most common structure, the wick should not be elevated too high above the surface of the oil, for, in that case, the capillary action by which the oil rises between the filaments of the cotton will not be able to raise it to so great a height. If the wick is too little elevated above the surface of the oil, there will not be a sufficient quantity of the oil converted into the gas, whose combustion constitutes the flame, and the flame will be too small.

Many lamps used by the Greeks and Romans, have been found in the ruins of ancient towns. These ancient lamps are of pottery, painted and sculptured with various ornaments, and of bronze. The surface of the oil in the reservoir is nearly on a level with the lighted part of the wick, which emerges from a projecting beak at the side of the reservoir.

Varieties in
the Structure of
Lamps.

The lamp commonly used in rooms at Florence consists of a round reservoir, with four beaks projecting from four opposite points of its circumference: through the middle of the reservoir a vertical stalk passes; and on this stalk the lamp may be raised or slid down. The stalk is fixed in a foot that rests on the table. The whole is made of brass.

A lamp, which affords a faint light, is made of a waxed wick, an inch long, passed through the centre of a thin round piece of cork, and of a piece of card placed above the cork. Some oil is placed on the surface of water in a glass tumbler, and the cork, with its wick, is laid upon the surface of the oil. This lamp, called a *veilleuse*, is commonly used in Paris for burning in bedrooms during the night, as rush lights are in London.

The lamp with a hollow cylindrical wick, which receives a current of air, both on the outside and the inside of the cylinder, is called, in England, an Argand lamp, from the name of one of the first makers. The principle of this lamp is described in the *Encyclopædia*. The wick in Argand's lamp, as first constructed, was raised by a rack and pinion; but the method now employed to raise the wick consists in a spiral notch, which goes round outside of the interior tube. The inside of the ring to which the wick is attached has a tooth which fits into this notch.

At fig. 2, Plate XCIV., is a representation of the most usual form of the Argand lamp. A is a reservoir, which is air tight at top, and has the neck immersed in oil, so that oil flows out of it only when the external air is admitted to ascend through the neck: it contains a short column of liquid, from the top of

which the pressure of the atmosphere is excluded, and therefore the column is sustained by the weight of the atmosphere pressing on its base, on the same principle as a bird-cage fountain. Lamps.

Oil is introduced into the reservoir A, by taking it off, and holding it with the neck uppermost. The sliding tube Q is pushed so as to uncover the hole *t*, and the oil is poured in by the hole *t*; when this is done, the hole is again covered by the sliding tube, and the reservoir A is replaced in F. When the lamp is to be lighted, the hole *t* is opened by depressing the sliding tube by its handle *z*, and the oil will flow out of A till it rise in F, and in the annular cavity that contains the wick to the level of the top of the hole *t*. When the oil in F is lowered by the burning of the lamp, so that the surface of the oil in F is below the upper part of the hole; then a bubble of air ascends into A, and a quantity of oil descends into F, till the surface of the oil rises again to cover the upper part of the hole. It sometimes happens that the air in A is heated by the warmth of the room, and then too great a quantity of oil descends into F, in consequence of the expansion of the hot air in the upper part of A, so that the oil, not being all consumed in the wick, falls down through the tube *g*, and may even run over from the cup P. This is a considerable inconvenience attending oil reservoirs of the construction here mentioned. The hole *t* is closed by drawing up the sliding tube Q, when the lamp is not burning, in order that the lamp may be inclined, without making the oil descend from the reservoir.

The cylindrical part, where the flame is produced, is composed of three tubes, *d*, *f*, *g*. The tube *g* is soldered to the bottom of the tube *d*, just above *o*, and the interval between the outer surface of the tube *g* and the inner surface of the tube *d*, is an annular cylindrical cavity closed at bottom, containing the cylindrical cotton wick immersed in oil. The wick is fixed to the wick tube, which is capable of being moved spirally; within the annular cavity is also the tube *f*, which is capable of being moved round, and serves to elevate and depress the wick. P is a cup that screws on the bottom of the tube *d*, and serves to receive the superfluous oil that drops down from the wick along the inner surface of the tube *g*. The air enters through the holes *o o*, and passes up through the tube *g* to maintain the combustion in the interior of the circular flame. The air which goes to perform the combustion on the exterior part of the wick enters through the holes *m*, with which *r n* is perforated. When the air in the chimney is rarified by the heat of the flame, the column of the atmosphere, of which the chimney is the base, becomes lighter than the surrounding columns; and the surrounding columns, pressing with their excess of weight, enter the lower part of the chimney, and pass upward, with a rapid current, to restore the equilibrium between the adjacent columns of the atmosphere.

In some lamps, above the orifice of the tube *g*, and nearly at the height of the top of the flame, there is placed a circular plate of metal, of the same diameter as the tube: this has the effect of turning the

Lamps current of air into that part of the flame where smoke would otherwise be produced. The same effect is obtained by the contraction of the cylindrical glass chimney at R G: the contraction of the chimney was commonly employed in Paris before it was used in England.

The oil flows from the reservoir A and F through N, and occupies the cavity between the exterior surface of the tube g, and the inner surface of the tube d. The oil rises in the annular cylindrical cavity between these two tubes to the level of the opening l. The part m is a short tube, which receives the circular wick, and slides freely on the tube g. The tube g has a hollow spiral groove on its exterior surface, into which enters a pin k, connected with the wick-tubes n s. The wick-tube has a catch, which works in a perpendicular slit in the tube f, and, by turning the tube f, the wick-tube will be raised or lowered, r n fits on the tube l' r n is fitted to receive the glass chimney R G: one of which is seen at s; a wire s is attached to the tube f, and is bent over the edge of the tube d, and descends along the outside of the tube d. The part n r that supports the glass chimney, is connected, by four other wires, with the ring y, which surrounds the tube d, and is capable of being moved round. When n r is turned round, it carries round along with it the ring y the wire s, and the tube f, and thereby operates the elevation and depression of the wick.

The glass chimney which rests on R N is wider at bottom, and then is contracted at R G, for the purpose of making the air rush upon the external part of the circular flame in a denser current.

In the most simple construction of lamps the surface of oil in the oil reservoir is nearly on a level with the flame, because the capillary attraction of the wick can only raise the oil a little above the surface of the reservoir. The surface of the reservoir also is considerable, that the lamp may burn for a sufficient length of time, before it has consumed so much oil as to reduce the level of the oil below the reach of the action of the capillary attraction of the wick. Mechanists have contrived and executed lamps of various forms, with the view of removing the inconvenience of the shadow of the reservoir which is inherent in the common lamp with one lateral beak.

One of the contrivances for diminishing the bulk of the part in which the wick is immersed, and for obtaining a supply of oil, is the bird-cage fountain reservoir described above, as being usually applied to argand lamps. This kind of reservoir is described by Cardan, and a lamp fed by it is mentioned by several writers under the name of Cardan's lamp.

Baptista Porta, in treating of oil reservoirs of the kind just now mentioned, proposes that, for large lamps with many wicks, the reservoir should be placed above and without the room, and should communicate with the lamp within by a pipe. In this way, the oil would not be liable to be pressed out too rapidly by the expansion of the air in the reservoir occasioned by the heat of the room, and several methods have been contrived for the purpose of placing the luminous part of the wick on the up-

per end of a stalk, so that very little of the sphere of rays, proceeding from the lighted wick, may be intercepted by the opaque part of the lamp. The following are some of these methods:

A lamp, called the Amiens lamp, commonly used in Paris by the poorer classes, is in the form of a candle. The lighted part of the wick is at top; the lower part of this cylinder, which is of tin, has a valve opening upwards, and is moveable up and down in another cylinder, which has a valve opening upwards. This valve is plunged in the reservoir of oil, when the wick is in want of oil, the oil is pumped up by moving vertically the tin cylinder which contains the wick. Lamps of this kind are described in the *Transactions of the Academy of Sciences* for 1755, p 139, and for 1760, p 118.

A lamp for reading is made by Carcel of Paris in which the oil is raised to the wick by means of a pump. The pump is moved by watch-work, composed of wheel and pinion, and a spring, which is wound up when the lamp is to be lighted.

In the Xth Vol of the *Philosophical Transactions*, St Clair, in a letter to Hooke, describes a lamp, in which the oil floats on water. A tube passes from the upper part of the vessel down to the water, and through this tube water is dropped, by means of which the surface of the oil is always maintained at the same level, whilst it is consumed by the flame in the wick.

In the lamp constructed by Mr Kier of Kentish Town, the oil is raised to the wick, and sustained by a column of a solution of salt in water. This liquid, being of a greater specific gravity, a column of it counterbalances a longer column of oil. The solution of salt is made of such a specific gravity, that it will support a column of oil four-thirds of its own height. This is nearly the specific gravity of the heaviest saline solution that is known to exist in any great body of natural water, namely, in the Dead Sea, the weight of the waters of this sea, of distilled water, and of oil, being in the relative proportions of 120, 100, 92. To have an idea of this lamp, imagine a syphon with two upright branches, and the junction of the branches at the bottom. The shortest branch has a bulb at top. The longest branch has a bulb near its lower extremity. The shortest branch is filled with a solution of salt, whose upper surface is in the superior bulb. The longer branch contains the oil, and in its upper extremity the wick is placed. In the lower bulb the surface of the oil rests upon the surface of the solution of salt.

The bulbs serve as reservoirs, prolonging the action of the machine; by means of the bulbs and the greater specific gravity of the solution, it is effected, that the abstraction of a considerable quantity of oil by the combustion in the wick occasions but a small depression in the upper surface of the solution; the height of the sustaining column of solution will become shorter in proportion as the column of oil which it counterbalances is consumed; but this diminution of the height of the column of oil will be slow, and therefore the column of oil will for a considerable time be of sufficient length to reach the wick. Suppose an inverted syphon, of

Lamps.

equal diameter throughout, the shorter leg of which contains a column of solution of salt, whose height is 7.5, and this counterbalances a column of oil, whose height is 100, in the longer leg; if now the column of oil in the longer leg be diminished in height by 10, the counterbalancing column of solution will diminish to 67.5, being 7.5 shorter than at first. But if the syphon, instead of being of equal diameter, has two dilatations or reservoirs, whose horizontal section is ten times the area of the tube of the syphon, one of the reservoirs being placed at the top of the short branch, so as to contain the upper surface of the solution of salt, and the other at the bottom of the long branch, so as to contain the surface where the oil rests upon the solution, then, if the same quantity of oil, as in the former example, is taken from the top of the longer leg of the syphon, the column of oil will only fall one-tenth of what it did in the undilated syphon of equal diameter, and the solution of salt will diminish one-tenth of what it did in the syphon of equal diameter.

The oil reservoir and the wick remain stationary, and do not descend as the oil is consumed. This descent takes place in two lamps now to be mentioned, because in these two lamps the oil reservoir swims in liquid that acts as a counterpoise.

In the lamp contrived by the Chevalier Edelkrantz of Stockholm, the oil reservoir floats in mercury, and the column of oil is maintained at the requisite height by the counterpoise of a column of mercury; in proportion as the oil is consumed, the oil reservoir and the wick which is connected with it sink.

The general structure of this lamp may be understood by conceiving a flask, with a long narrow neck, and enlarged at the under part. The flask is heavy enough to swim, when it is placed in mercury, with part of its under part immersed. The bottom of the flask is open. The flask being placed in mercury, is made to float with its neck perpendicular. Oil is poured in at the neck till the flask is full. Then the surface of the mercury at the bottom of the flask and within the flask will be depressed by the weight of the column of oil that rests upon it; and the surface of the mercury on the outside of the bulb or lower part of the flask will stand higher than the surface of the mercury within the flask. The height which measures the difference of level of the two surfaces of mercury, will be the height of a column of mercury of equal weight with the column of oil that is in the flask; and as mercury is about 14.5 times the weight of oil, the difference of level of the two surfaces of mercury will be $\frac{1}{14.5}$ of the height of the oil in the flask. In proportion as oil is abstracted from the upper end of the tube by the combustion in the wick, the height of the column of oil is thereby diminished, and the two surfaces of mercury will come nearer together, till the flask sinks a little in the mercury. As the area of the horizontal section of the lower part of the flask is much greater than the area of the section of the neck, and as the specific gravities of mercury and oil are very different, it follows, that, to restore the equilibrium after the abstraction of a column of oil from the wick, the sur-

face of the mercury within the lower part of the flask will rise by a much shorter column.

In the lamp invented by Mr. Barton, Comptroller of his Majesty's Mint, a solution of salt in water is used as a counterpoise to the oil. The combination consists of a light flask, open at the bottom, floating in a solution of salt, so that, when oil is poured into the flask, the surface of the oil in the neck of the flask stands at a higher level than the surface of the saline solution, in which the flask swims. The wick is at the upper end of the neck of the flask, and as the area of the horizontal section of the bulb or lower part of the flask is much greater, suppose 20 times greater, than the area of the section of the neck of the flask, it will happen, that when a column of oil an inch high is abstracted from the neck of the flask, the height of the rise of the surface of the solution in the bulb or lower part of the flask will be only $\frac{1}{20}$ th of an inch. This lamp is represented at fig. 3, Plate XCIV.

T is the oil reservoir, from which the oil passes upwards to the wicks *m, w, w*. The oil reservoir is open at bottom, at *h*. This is preferable to the mode of making the reservoir with a perforated bottom, that screws off, for the purpose of cleaning the reservoir. The fluid B, in which the oil reservoir is immersed, is a solution of salt in water. This liquid is contained in a vessel RMO, which can be unscrewed at O, for the purpose of taking out the oil vessel. N and Y are two floats fixed to the oil reservoir and its tube. The column of the solution of salt *c, h*, presses against the oil at the open bottom of the reservoir, and maintains a column of oil in the tube to the height *e*; to this point *e* the wick descends, and raises the oil to the flame by the capillary attraction of its fibres. The specific gravities of the oil and the solution of salt must be inversely as the heights *c, h*, and *h, e*, that is, the specific gravity of the solution of salt must be made to bear to the specific gravity of the oil the same proportion that the perpendicular height *c, h*, bears to the perpendicular height *e, h*. As the oil is consumed, the water enters the hole at the bottom of the oil vessel, the surface of the water at *c* sinks, and the oil reservoir, with the tube and wicks attached to it, sink also. The upper part of the vessel R should be of a capacity a little less than the capacity of the oil reservoir, so that, when the water has displaced the oil, and filled the oil reservoir, the float Y may be at the bottom of the enlarged part of the water vessel R. To prepare the lamp, the exterior vessel is filled with solution of salt by the opening at *l*; the solution passes into the oil vessel by the open bottom *h*, and the oil vessel rests on the bottom of the exterior vessel. The oil is then poured in through the tube *c*. The oil passes into the oil reservoir, expels the water, and floats the oil reservoir, raising the surface of the water in R.

An inconvenience affecting Barton's lamp is, that the solution of salt, by the gradual evaporation of the watery part, becomes more dense, and capable of supporting a higher column of oil than it did at first. The lamp of Edelkrantz, which floats on mercury, is not liable to this inconvenience, because the mercury does not alter its density by evaporation.

Lamps.

Both these floating lamps have the inconvenience, that the oil is made to run over at the wick by any accidental shock which depresses the floating part of the lamp.

Several lamps have been constructed in which the oil is raised by the principle of the fountain of Hero, of Alexandria, which is known as being employed to raise water in the mines of Chemnitz, in Hungary. In Hero's writings, the application of this machine to raise oil to a lamp is described. Lamps of this construction were made some years ago in Paris by Girard de Marseille. Of this kind is the hydropneumatic lamp made by King, tin and japan manufacturer, of Snowhill, London. This lamp is formed externally like a column, 18 inches high, and 4 inches in diameter; it is made to contain oil enough to last for five or six hours. An idea of its general principle may be formed by means of the diagram at fig. 5, Plate XCIV. in which there is a descending tube, with a bulb, at A, at top. The upper part of this bulb is open. The tube, at its lower part, is curved upwards, and dilated into a second bulb, B. The tube contains oil, the upper surface of which is in the upper bulb A, and its other surface is in the lower bulb B. From the top of the lower bulb B, a tube proceeds to the top of another bulb, C, placed higher than the upper bulb A, of the first tube. This third bulb, C, contains oil, and from the bottom of this third bulb the oil rises in a tube. At the upper end, W, of this tube, the wick is placed. The whole machine is closed, and air-tight, except at the openings of A and W, and at these openings the pressure of the atmosphere acts. Thus the column of oil contained in the first tube and bulbs A, B, presses, with its own weight, and the weight of the atmosphere, on the confined air contained between the second bulb, B, and the third bulb, C, and raises up a column of oil from that third bulb. The top of this column, so raised, is at a higher level than the top of the oil in the first tube, because the bottom of the column, which is raised, is at a higher level than the bottom of the column in the first tube. The whole machine is a syphon, in which a first column of oil, of the perpendicular height AB, supports a second column of oil, CW, not of a greater height than the first column, but, by means of the column of air, BC, interposed between the two columns of oil, it is effected that the extremity, W, of the second column of oil, is much higher than the upper surface, A, of the first column of oil. In the lamp constructed on this principle by King there is a plug and valve, which serve for introducing the oil, and other particular contrivances. When the oil is to be poured in, the lamp is inverted.

A lamp, of which the reservoir for the oil is in the form of a hollow ring, was contrived by Count Rumford, and is described by him in *Nicholson's Journal*, Vol. XIV. 1806, p. 23. The lamp is in the centre of the ring, with which it communicates by three straight tubes, in the direction of radii of the ring. The stoppers which close the apertures by which the oil is poured into the ring have a small hole, which allows the atmosphere to press on the surface of the oil in the ring, and thereby permits it to flow freely to the wick. This small

hole may also be placed in some other part of the ring, and not in the stopper. The ring supports an hemispherical shade of roughened glass, or of gauze. These glass shades are made rough, not by grinding, but by laying a coat of powdered glass on the smooth surface of the shade, and then exposing it to the heat of a furnace, so that the powdered glass becomes adherent, and produces a rough or frosted surface. This method of frosting glass is practised in some glass-houses situated in that district of Staffordshire called the Potteries. Lamps of this construction may be suspended from the ceiling, or placed on a stand, and are now frequently used in rooms and shops in London and Paris. They are called in London French lamps.

Hooke, in his treatise entitled *Lampas*, published in 1677, describes eight contrivances for supplying oil to a lamp equably, and as long as there remains any oil in the reservoir. This he effects by different methods of counterbalancing the oil. These inventions display Hooke's ingenuity and great knowledge of mechanics, but require nice workmanship, and are not applicable to practical purposes. These counterpoises of Hooke also serve to form a vessel so that the whole liquid may be drawn from it in an equable stream, by tapping the vessel at the top, and to make the descent of the surface of a liquid and its discharge constant and equable, in a clepsydra for showing the hour.

Porter's automaton lamp, constructed in London in 1784, is something similar to some of Hooke's contrivances for producing an equable supply of oil to the wick, as long as there remains any oil in the reservoir. It does not require such delicacy of execution as his counterpoised lamps. Porter's lamp is a tin box, the vertical and longitudinal section of which is a rectangular parallelogram, elongated horizontally, of which call AB the two upper angles, CD the two lower. This parallelopipedal box is suspended on an axis near the upper surface of the box, at a place which may be denoted by X. The axis is nearer A than B; at A is the wick, and a tube going down to the bottom of the box, along the side of the box AC. When the box is full of oil, then the space XB, behind the axis, being full of oil, counterpoises the shorter space XA. AB, the long side of the box, is horizontal; and the line drawn from the axis of suspension down to the centre of gravity is perpendicular to AB. But, when the surface of the oil falls below the axis, then the box turns on its axis, the side A falls, and B is elevated; A being heavier, by reason of the wick and wick tube, and the side AC assumes a lower position, in proportion as the oil is consumed; the line drawn from the axis down to the centre of gravity becoming more and more oblique to AB. The operation of this lamp depends upon the position of the axis X, and the weight of the wick-tube, which must be accurately proportioned, the one to the other, by trial.

LAMPS FOR LIGHT-HOUSES.

Light-houses are now generally lighted with Argand lamps, which have hollow cylindrical wicks placed before reflecting mirrors. Several of these

Lamps for Light-houses.

Lamps for
Light-
houses.

lamps are fixed on a frame, and protected from the weather by glass windows. The lamps of light-houses are fed with oil, and in some places with pit coal gas, as in a light-house near Trieste, afterwards mentioned.

In many of the light-houses on the British coast, the frame on which the lamps are fixed is made to revolve by means of clock-work, so that to a spectator, situated in the circle of which the light-house is the centre, the light appears at its brightest at the end of a stated period of time, which is generally one or two minutes. The revolving of the light enables seamen to distinguish the light-house from the light of lime-kilns or other fires upon the coast. This distinction is of great importance, for shipwrecks have happened in consequence of mistaking the light of lime-kilns for the light of a light-house. The light is, in some light-houses, made of a red tinge to distinguish it from some other light-house not far distant. The red colour of the light is produced by placing windows of red glass before the lamps. Red is the only colour that can be given to the light in this way. When stained glass of other colours is placed before the lamp, it is not found to produce a change in the colour of light seen at a distance; the blue or green colour of the glass becomes insensible when seen through a great body of air which has itself a blue colour.

LAMPS FOR LIGHTING STREETS.

Till within the last six years, the street lamps, used in London and in other parts of Britain, consisted almost uniformly of a deep inverted bell-shaped glass lantern blown of one piece, and suspended by the edge in an iron ring; with a tin conical cover perforated to give issue to the smoke, and within the lantern, a flat oil vessel with two or more wick holders or beaks, projecting from its circumference. Many districts of London are lighted with lamps of this form; other districts employ several kinds of street lamps of a different form. The first of these new kinds were made under the direction of Lord Cochrane, and employed to light the streets in the parish of Saint Anne, Soho, London.

The lanterns which serve to protect the light from wind and weather in the new lamps in one district of London, are composed of four lateral panes and a bottom of glass, joined together by sheet iron, so that the lantern is in form of a truncated pyramid, inverted like the lanterns of the street lamps in Paris. In lanterns of this form some light is intercepted, and a shadow is thrown on the street by the metal that unites the panes. This defect does not occur in the lanterns of street lamps most commonly used in England, and made of one piece of glass blown into the form of a spheroid. The spheroidal lanterns deflect the light more, because they are more unequal in thickness, but this is a smaller inconvenience: the lanterns blown of one piece of glass are more easily cleaned. Many of the lanterns for gas lights are also made of panes in the above mentioned form; some are cylindroids blown of one piece with a hole in the bottom to admit air. In some of the new lamps, in London, which have lanterns of one piece of glass, the form of the lantern is

Lamps for
Lighting
Streets.

nearly cylindrical; in others, the lantern is not so deep as the lanterns of the old form. The new lamps have reflectors placed above the light, for the purpose of reflecting the light downwards on the foot pavement. These reflectors are of various forms, in some of the lamps, the four plane surfaces of the inside of the pyramidal cover of the lantern are made bright, and serve to reflect the light downwards. In other lamps the ceiling of the lantern is a reflector in form, having a small portion of a large curved surface with a chimney in the middle to give issue to the smoke. Others have two, and sometimes three, concave conoidal reflectors, whose vertices meet over the light, the axes of two of the reflectors being parallel to the direction of the street: at the point where the reflectors meet there is a chimney through which the smoke ascends. The reflectors require to be frequently wiped in order to keep them bright.

The oil vessels of the new lamps in London are of various forms; the beak, or part of the oil vessel under the wick, is made as narrow as possible, for as it is very near the flame, its shadow thrown on the street by the rays diverging from the flame is several feet in breadth. If the beak be an inch broad, and situate an inch under the flame, the shadow of the beak on the pavement, under the lamp, will be ten feet broad, if the flame is situate ten feet above the pavement. In some of the new lamps, the reflector placed above the light is made with its concavity so disposed at the edges, that the reflected light is thrown upon that part of the pavement which is under the oil holder. In Major Cochrane's lamps, the oil vessel consists of a bird-cage shaped reservoir, which allows a supply of oil to come down to the wick, when the surface of the oil in which the wick is placed has sunk to a certain point. The wick is double, consisting of two pieces of flat cotton web; between the wicks is a slit through which a current of air ascends to the flame, and on the outside of each wick is another slit; these slits admit currents to the exterior surface of the wicks. Each time that the lamp is trimmed two pieces of wick are inserted, just sufficiently long to last the time that the lamp is required to burn. Naptha distilled from pit coal is burnt in these lamps, and the light is brilliant like the light of coal gas. But the gas lights have the advantage of being unincumbered by the opaque substance of the oil vessel, which intercepts light, and casts a shadow on the street.

The street lamps in London are fixed at the end of iron rods which project from the walls of the houses. The lamp is, over the middle of the foot pavement, ten feet from the ground. There is a row of lamps on each side of the street, the principal street being fifty feet in width. In Paris, where many of the principal thoroughfare streets are not above twenty-five feet in breadth, the lamps are suspended over the middle of the street. A strong rope is made fast to the walls on each side of the street, and to this rope a smaller rope with the lamp is attached. The smaller rope passes over pulleys, and comes down into an iron box, where it is fixed on a hook. The iron box is unlocked, and the lamp is let down and lighted with a candle. The light is

Lamps for
Lighting
Streets
||
Safety
Lamp.

placed before a silver-plated reflector. In Vienna the street lamps are fixed on the upper end of a post. The lamp is taken out of the lantern by means of a pole, and lighted at the foot of the post. This saves the inconvenience which results to passengers from the mode of lighting lamps, by a man with a ladder and torch, as practised in Britain. In most of the towns of Italy the streets are but sparingly lighted. The lamps are fixed at the end of iron rods which project from the walls of the houses. In some of them the light is placed in the focus of a parabolic reflector, or at the meeting of the vertices of two concave conoidal divergent reflectors situated above the light. The French, when masters of Italy, made regulations to improve the lighting of the streets.

In England whale oil is used as the combustible material in the street lamps; of late naphtha, obtained from the distillation of pit coal, has been used in a district of London which is lighted with Major Cochrane's lamps. This naphtha is a clear and colourless liquid, and is found to give a good light; it requires to be prepared with particular attention; that made at the gas light work is said to be too easily inflammable. In Paris rape seed oil, and poppy seed oil, are used: these expressed oils are made in the north-eastern part of France and in Flanders. In the south of Europe olive oil of inferior quality and walnut oil are used. Street lamps lighted with the gas distilled from pit coal are now (1821) employed in the principal streets of London, Edinburgh, Glasgow, Liverpool, Manchester, Birmingham, Sheffield, and other cities in Britain. The use of coal gas for giving light had made very little progress in France in 1818, being scarcely employed even in Paris, and we believe not at all at Lyons, although pit coal is abundant and commonly used as fuel there. In 1818, pit coal gas was used for lighting a light-house on the Adriatic in the dominions of the House of Austria near Trieste; the gas being obtained from the coal wrought in the adjacent country.

SAFETY LAMP.

This lamp was constructed for the purpose of giving light in mines where fire damp prevails. In many of the collieries of Britain, Flanders, and other countries, fire damp, consisting of carburetted hydrogen, issues from different parts of the strata of coal when the coal is worked; and when the fire damp is mixed with a certain proportion of atmospheric air, it explodes by the flame of the miner's candle, burning the workmen severely, and often depriving them of life. Vegetable substances, in the slow decomposition which takes place in them, in the process of putrefaction, give out inflammable gas. This is seen when the leaves of plants fall into water and become putrid, inflammable gas then rises to the surface in bubbles, and is inflamed if a light be applied to the surface of the water. Vegetable matter gives out inflammable gas also in the rapid decomposition occasioned by fire. The flame of vegetable substances consists of the inflammable air resulting from their decomposition, and burning with the addition of the air of the atmosphere. Pit coal consists of the remains of large quantities of ve-

getable substances, and the fire damp of coal mines may be considered as the produce of the putrefaction which the vegetable matter has undergone, or of some decomposition that the coal is still undergoing. Sir Humphry Davy found that, on breaking some masses of coal under water, inflammable gas was given out. In some places blowers of fire damp issue out at the surface of the earth. A quarter of a mile from Pietra Mala in the Apennines, on the road from Bologna to Florence, there is a blower of inflammable gas issuing from the ground, and proceeding from strata of schistus, and perhaps of coal; Sir H. Davy analysed this gas, and found it to be carburetted hydrogen, like the fire damp of the coal mines. Another blower of the same kind exists on the side of a mountain near the shore of the Gulf of Adalia, in Lycia, on the south coast of Asia Minor. In mines wrought to obtain metals and salt, where there are no strata of vegetable matter like coal, it does not appear that the fire damp occurs.

The merit of that very ingenious and most useful contrivance the *Safety Lamp* is wholly due to Sir Humphry Davy. After having made many experiments for the purpose of forming a lamp to give light in coal mines affected with fire damp, without occasioning explosions which frequently prove fatal to the miners, he found that wire gauze, of which the apertures occupy more space than the cooling or radiating surface of the wire, so as to be permeable to air and light, offered a perfect barrier against explosion; because, although the gas was inflamed within the inclosures formed by the wire gauze, yet the heat being communicated to the numerous surfaces of the wire, the gas on the outside of the wire inclosure was not inflamed. Wire gauze is the best material for safety lamps, as it affords the greatest extent of radiating surface, and by cooling, prevents all explosions that require a temperature higher than the temperature of the atmosphere. An example of the radiating and cooling action of wire is seen in the fire guards of wire, which are hung upon the ribs of fire places in rooms to prevent sparks from being thrown into the room. These fire guards, although they are very near the fire, do not become hot. The apertures of the wire gauze must be smaller, and the wire, which is the radiating and cooling surface, must be in greater quantity; in proportion as the gas in which the lamp is to be used is more inflammable. The fire damp in coal-mines is in almost all cases carburetted hydrogen; and for excluding explosion from a lamp in that gas, it is found that the wire gauze should contain 784 apertures in a square inch.

The wire gauze should be of iron or copper. Fine brass wire is improper, because it is too easily combustible by reason of the zinc it contains. The iron wire should not be tinned, tin being too easily combustible. The body of the lamp should be of copper riveted together, or of mussy cast-brass or cast-iron. The screws should fit tight; no aperture, however small, should be suffered to exist in the body of the lamp; and the trimming wire should move through a long tight tube.

The safety lamp is represented in Plate XCIV. fig. 4. A is the cistern containing the oil; B the

Safety
Lamp.

Safety
Lamp.

brass rim to which the bottom of the wire gauze cylinder is fastened by a screw to prevent it from being separated from the lamp; C is the safe feeder through which oil is poured into the lamp; E the safe trimmer, a wire which passes through a safe tube, for the purpose of raising and trimming the wick; F the wire gauze cylinder. The longitudinal suture where the two edges of the piece of wire gauze that forms the cylinder meet, must be well doubled and fastened with wire. If the cylinder is of twilled wire gauze, the wire should be of iron or copper, at least of the thickness of $\frac{1}{16}$ of an inch; if of plain wire gauze, the diameter should not be less than $\frac{1}{60}$ of an inch. The number of apertures in a square inch should not be less than 784. The wire gauze cylinder F is closed at top by a circular piece of wire gauze, and above this is placed a second top, G, which fits on the cylinder like a cap. In the figure the circular wire gauze top of the wire gauze cylinder is seen at G through the wire gauze of the cap. The circular top of this wire gauze cap is $\frac{1}{2}$ of an inch above the top of the wire gauze cylinder F. I I are thick wires surrounding the wire gauze cylinder, to preserve it from being bent by external force. K is a ring to hang up the lamp, or to hold it by. The most convenient size for the safety lamp is a span, that is, from 8 to 10 inches high, the wire gauze cylinder being 2 to 2 $\frac{1}{2}$ inches in diameter.

The wire gauze, when choaked with coal-dust, requires to be cleaned by means of a brush, in order to transmit the light.

In figure 4, a lens of glass, L, is placed before the light, sometimes a piece of tin is placed within the cylinder to act as a reflector.

The light of the safety lamp, without a reflector, was found to be nearly equal to the light of a common miner's candle.

Flame produced by the combustion of explosive gases may be extinguished by colder metal. The temperature of metal, even when heated to a white heat, is less than the temperature of flame, and therefore red hot wire gauze in sufficient quantity, and of the proper degree of fineness, will abstract sufficient heat from the flame of carburetted hydrogen or fire damp to extinguish that flame.

Flame, in all cases, is considered to be the combustion of an explosive mixture of inflammable gas and air. If a piece of wire gauze is held over the flame of a lamp, it prevents the flame from passing. The air that passes through is very hot, and is in the state of an explosive mixture, for it will be inflamed if a lighted taper be presented to it. But it is cooled below the exploding point, by passing through the wires, even if the wires are red hot; it is also cooled by being mixed with a considerable quantity of air comparatively cold. The temperature of visible flame is very high, as is seen by the fusion of a small filament of that difficultly fusible metal platinum, which happens when the filament is held in the flame of a candle. A considerable mass of heated metal is required to inflame fire damp. An iron wire of $\frac{1}{32}$ of an inch in diameter, and 8 inches long, red hot, when held perpendicularly in a stream of fire damp, did not inflame it. But wire of

the same size, when six inches of it were red hot, and when it was held perpendicularly in a bottle containing an explosive mixture, so that successive portions of the gas were heated by the wire, produced an explosion.

The action of the safety lamp may be exhibited in the chemist's laboratory, by pouring some ether into the bottom of a large jar; the vapour of the ether mixing with the air, produces an explosive atmosphere. When the safety lamp is lighted and placed in the jar, the explosive mixture from the ether will burn within the wire gauze lamp, without inflaming the gas that is without it.

The workman who has only a single gauze lamp, and finds the temperature of the wire increasing rapidly by the fire damp from a blower, can easily diminish the heat by standing between the current and the lamp, that is to say, to the windward of the lamp, or by sheltering the lamp from the current by interposing his clothes; or, by bringing the lamp nearer the orifice from which the fire damp issues, he may extinguish it. There never can be any occasion for the workmen to place the lamp in the exact place, when two currents, one of common atmospheric air, and the other of fire damp, meet each other.

When the fire damp is inflamed in the wire gauze lamp, coal-dust thrown into the gauze cylinder burns with strong flashes, but the explosion is not communicated to the external fire damp by this means.

Phosphorus, sulphur, pyrites, or gunpowder, would produce explosion, by being applied to the outside of the wire gauze cylinder; and sulphur, to produce this effect, must be applied in large quantities, and blown upon by a current of atmospheric air. But there is little danger of these substances being accidentally applied to the safety lamp in mines.

When a wire gauze lamp is made to burn in a very explosive atmosphere at rest, the heat of the wire gauze, when the fire damp is burning within the lamp, soon arrives at its maximum, and then diminishes. The coally matter also, from the decomposition of the oil, chokes the upper apertures of the wire gauze, and thus gradually diminishes the heat by diminishing the quantity of gas consumed. Wire gauze lamps which had been used by workmen for several months, and which had been often red hot in explosive atmospheres, were nevertheless still unimpaired and perfect.

Where the lamp is placed in a current of explosive gas a greater heat is produced, and in this case the radiating or cooling surfaces should be increased. Twilled gauze, or a double or triple fold of wire gauze on one side of the lamp, or a screen of metal between the lamp and the current, or a semicylinder of glass or mica within, answers the object of preventing the heat from rising to redness.

If the heat of the iron wire gauze rose to that of a strong welding heat, a circumstance which never could happen in a colliery, then the iron wire would burn, and the lamp would be no longer safe.

From a mine of Mr Lambton's there is a violent blower of fire damp conveyed to the surface, upon which the following experiment was made. A brass pipe was fixed upon the blower-tube, so as to make

Safety
Lamp.

Safety
Lamp.

the whole stream of fire damp pass through an aperture of less than half an inch in diameter. The fire damp when inflamed issued from this with great violence and noise, forming a flame of five feet long. This blow-pipe was exposed at right angles to a strong wind. The double gauze lamps soon became red hot at the point of action of the two currents; but the wire did not burn, nor did it communicate explosion. The single gauze lamp did not communicate explosion as long as it was red hot, and slowly moved through the currents; but when it was fixed at the point of the most intense combustion, it reached a welding heat; the iron wire began to burn with sparks, and the explosion then passed.

In other experiments on this blower of fire damp, single wire gauze lamps, with slips of tin-plate on the outside, or in the inside, to prevent the free passage of the current, and double lamps, were exposed to all the circumstances of the blast; but the heat of the wire never approached near the point at which iron wire burns, and the explosion was not communicated. The flame of the fire damp flickered and roared in the lamps, but did not escape without the limits of the wire gauze.

The sparks from a flint and steel mill, a machine which sometimes has been used to give light in mines affected with fire damp, would most probably inflame such a current as the blower above mentioned, because the sparks elicited from steel by the collision of flint, are small portions of the steel in a burning state, as may be seen by collecting these sparks on a sheet of paper, and viewing them with a microscope.

The lamp without flame, which is sold as an object of amusement and curiosity, consists of a fine wire of platinum of $\frac{1}{32}$ of an inch in diameter, coiled into a spiral, and placed round the wick of a lamp fed with the spirit of wine, and a little above the wick; when the flame of the lamp is blown out, the heat which the wire has acquired is sufficient to keep up the slow combustion of the vapour of the spirit of wine, and this combustion continues to keep the platinum in an ignited state. The principle of this lamp without flame may be usefully applied to the safety lamp. By hanging some coils of fine wire of platinum above the wick of the lamp, it is believed that the coal miner will be supplied with light in mixtures of fire damp, which, from the small proportion of atmospheric air, are no longer explosive; and should the flame of the lamp be extinguished by the quantity of fire damp, the glow of the incandescent platinum will continue to give light, and the incandescence will cease when the air becomes unrespirable. Sir Humphry Davy found that a spiral wire of platinum, of $\frac{1}{60}$ th or $\frac{1}{70}$ th of an inch in diameter, suspended within the safety lamp, yields light in a mixture of fire damp with atmospheric air, in which the atmospheric air is in so small a proportion, that the mixture is not explosive. In this situation the heat is not sufficiently great to produce combustion with flame, and combustion without flame takes place. The platinum wire, heated by the flame of the lamp, retains its heat after the flame is extinguished, and this heat is sufficient to occasion a slow combustion or combination of the

elements of the fire damp with the oxygen of the atmospheric air; this slow combustion produces sufficient heat to keep the platinum in a state of ignition. Platinum and palladium are the only metals found to produce this effect, because these two metals are of a slow conducting power and capacity for heat. This phenomenon takes place in mixtures of gas where there is common air enough to support the respiration of human beings.

At Wallsend and other extensive collieries near Newcastle, in Northumberland, the following regulations respecting the safety lamps are observed. A steady man is employed to take charge of the lamps, and he is responsible for keeping them in good order. A chamber is allotted him, in which he keeps oil, cotton, and spare lamps; the chamber is in a secure part of the mine, as near the workings as possible. The brass collar of the wire gauze cylinder is secured to the bottom of the lamp by a lock, which can be opened only by the lamp keeper; so that the workmen cannot separate the wire gauze cylinder from the bottom of the lamp. After finishing their day's work, the colliers bring the safety lamps to the lamp keeper's cabin. The lamp keeper unlocks the lamps, keeps the bottom, and allows the colliers to take the wire gauze cylinders home for the purpose of cleaning them. When the colliers return to their work next day, the lamp keeper having replenished the lamps with oil and cotton, lights the wicks, screws on the gauze cylinders, and examines them carefully; if any defect appears in the gauze, the lamp is set aside to be repaired. The lamp keeper's business, during the day, is to walk leisurely through amongst the workmen, carrying some spare lamps with him to replace those which happen to be extinguished.

(v.)

LANARKSHIRE, or CLYDESDALE, a county in Scotland, situated between $55^{\circ} 20'$ and $55^{\circ} 56'$ north latitude, and $3^{\circ} 25'$ and $4^{\circ} 22'$ west longitude; is bounded on the north by the counties of Dunbarton and Stirling, on the east by those of Edinburgh, Linlithgow, and Peebles, by Dumfriesshire on the south, and the shires of Ayr and Renfrew on the west. In length, from north to south, it is about 17 miles; its greatest breadth, from east to west, is 32, and it extends over 870 square miles, or 556,800 English acres, of which more than a third is fit for cultivation. It is divided into three Wards; the Upper, of which Lanark is the chief town, contains about two-thirds of its area, on the east, south, and south-west, the greater part mountainous; the Middle, having the town of Hamilton in its centre, stretches along the west and north; and the Lower, which contains the city of Glasgow, and a small tract around it.

This extensive district presents great variety of surface. Some of the mountains in the Upper Ward, where it is bounded by Dumfriesshire, are about 3000 feet high; and Tinto, on the northern boundary of the hilly district, is nearly 2300. Leadhills, a village on its southern extremity, is 1564 feet above the level of the sea. But in proceeding along the banks of the Clyde, north from Tinto, the face of the country softens down to gentle elevations and depressions, and for 12 miles the river winds slowly

Safety
Lamp
Lanarkshire.

Lanarkshire. through beautiful meadows. The Middle Ward is much less elevated, few of the heights being more than 700 feet above sea level; the town of Hamilton is only about 120; yet there are no plains of any extent except along the banks of the Clyde, and a considerable part of the surface is covered with moss, in many places of a great depth. Of the Lower, the greater part is a highly ornamented district, particularly the banks of the Clyde, which are thickly planted with villas, the summer residence of the wealthy inhabitants of the city of Glasgow.

Rivers.

The principal river, and, in a commercial point of view, the greatest in Scotland, is the Clyde, from which the county is frequently called *Clydesdale*. It has its rise in the ridge of mountains which separate Lanarkshire from Dumfries-shire, and flowing first north and then north-west, through the middle of the county, falls into the frith of the same name above Greenock, carrying with it the waters collected from 1200 square miles. The principal streams which join it on the south are Duneaton, Douglas, Nethan, Avon, and West Calder, and on the north the Medwin, Mouse, South and North Calders, and Kelvin which separates Lanarkshire from Dunbartonshire. The Clyde is navigable to Glasgow for vessels drawing nine feet of water, and two miles higher for smaller vessels. Most kinds of the fish found in the other rivers of Scotland are also abundant in the Clyde, particularly salmon. The celebrated falls have been described in the *Encyclopædia*, under the article CLYDE.

Minerals.

Sandstone and limestone are the prevailing rocks in the lower parts of Lanarkshire, and argillaceous schistus in the high grounds. In the Cathkin hills, near Glasgow, there is a number of basaltic columns, more than 40 feet high, inclined at an angle of about 70°. Ironstone abounds, and is wrought to a great extent at several large establishments. On the southern extremity are the well-known lead mines belonging to the Earl of Hopetoun, from which the village of Leadhills takes its name. In the same quarter gold was discovered in the time of James III., and afterwards collected in considerable quantities. But coal is by far the most important of its mineral treasures. It is supposed to stretch throughout an area of about 70,000 acres, and including the different seams to be about five feet thick. The field near Glasgow contains eight seams, one of them seven feet thick, the whole amounting to upwards of 30 feet. There are several good seams of cannel or candle coal in different parts of the county. This kind has been long used by the lower classes for lighting their houses, and it is known to yield more gas than common coal.

Estates.

The valued rent of Lanarkshire is L. 162,118, 10s. 10d. Scots; and the real rent of the lands, mines, and quarries, in 1811, was L. 298,019, 3s. 1d., and of the houses L. 286,071, 13s. 5d. Sterling. More than three-fourths of the county is the property of great landholders, and almost half the valued rent is divided among estates of upwards of L. 1000; but small properties are very numerous, the far greater number being below L. 100 of valued rent. These small estates, with many of the class

immediately above them, are cultivated by their Lanarkshire. owners; the large ones are let out to tenants on leases, except the inclosed grass lands, a great part of which is let out from year to year for grazing only.

The arable land is, for the most part, divided into Farms. to farms of a moderate extent, held on leases for 19 years; but it is not an uncommon practice to let the grazing lands for two or three crops only, for which a high rent is often obtained. In 1798, according to the *Agricultural Survey*, the sheep pastures in the mountain districts yielded a rent of from 6d. to 1s. 6d. the Scots acre, and the arable land in that quarter 8s. In the Middle Ward, the wastes were still less valuable than in the Upper, and its arable land was estimated at 14s. an acre. In the Lower Ward, the average rent was computed to be 25s. It is probable that all these sums may now be nearly doubled. Much of the arable land in the first division is dry and fertile; clay prevails in the second and third; and along the banks of the Clyde there are considerable tracts of an alluvial description.

As this county slopes to the west almost through- Climate out its whole extent, the Atlantic exerts a powerful influence on its climate. For about two-thirds of the year, the wind blows from the south-west and west; intense frosts are of short duration, and snow seldom lies long in the lower districts; but, from the general humidity of the atmosphere, and also of the soil, seed-time and harvest are often late. In regard to heat, there is a considerable difference between the Upper and Middle Wards, the thermometer on the same day commonly standing several degrees higher in the latter than in the former. Its range is from 11° to 85°. The quantity of rain that falls at Glasgow varies from 19 to 36 inches. Lanarkshire is, therefore, upon the whole, less favourable to the culture of corn than the eastern counties of Scotland.

The dairy is accordingly an object of considerable Dairies importance here, and is carried on in all its branches. Besides the dairies kept in and near the city of Glasgow, for supplying the inhabitants with milk, cream, and fresh butter, a great number of cows are kept in the Middle and Lower Wards, the milk of which is applied to the making of butter, new milk, and skim milk cheese, and the fattening of calves. The best cheese is similar in quality to the Dundee cheese of Ayrshire. Clydesdale has been long famous for its draught horses. See AGRICULTURE and DAIRY, in this Supplement.

Besides the grounds in the environs of Glasgow, Orchards from which the city is supplied with small fruits and culinary vegetables, there are considerable orchards in the county. Most of them are on the banks of the Clyde, from the lowest fall to the influx of the South Calder. The trees are chiefly apple, with a mixture of pear, and some plums. About 20 years ago, 300 acres were occupied with orchards, and their extent now is said to be greater. The produce is extremely precarious, but the land, which is for the most part on the steep banks of the river, is of little value for any other purpose. A much larger extent of the banks is occupied by coppice; and throughout the county a considerable space has

Lanarkshire. been allotted to plantations, which consist chiefly of Scots fir and larch.

Inland Navigation

Lanarkshire is traversed by good roads in all directions; and, besides the Clyde, the navigation of which has been much improved by deepening and confining the bed of the river, it has the advantage of possessing an inland navigation, by means of three canals. These are, the *Forth and Clyde Canal*, which enters it on the north, in the parish of Calder, and, after a course of eight miles, passes into Dunbartonshire at the aqueduct over the Kelvin;—at Stockingfield, a collateral branch proceeds to Port Dundas, at Glasgow; the *Monkland Canal*, from the coal-works in the parishes of Monkland, to the Forth and Clyde at Port Dundas; and the *Ardrossan Canal*, which is completed, from Port Eglinton, near Glasgow, to the village of Johnston, a distance of eleven miles, and is intended to be continued to Ardrossan, on the coast of Ayrshire, 22 miles farther.

The city of Glasgow, with its manufactures and commerce, has been described in the articles GLASGOW in the *Encyclopædia* and in this *Supplement*. The other towns are, Lanark, Hamilton, Rutherglen, Biggar, Strathaven, and Kilbride. Lanark, the county town, and a royal burgh, 32 miles south-west of Edinburgh, and 25 south-east of Glasgow, was a place of importance so early as the time of Alexander I. In 1811, the parish contained a population of 5667. Hamilton is situated on the Clyde, 38 miles west of Edinburgh, and 11 south-east of Glasgow, with a population of 5453. In the neighbourhood is the seat of the Duke of Hamilton, and three miles below is Bothwell Bridge, noted for the defeat of the Covenanters, June 22, 1679; see HAMILTON, in the *Encyclopædia*. Rutherglen is a royal burgh, on the Clyde, 24 miles above Glasgow. See this also in the *Encyclopædia*. Biggar is a little market town, on the borders of Peebles-shire, 27 miles south south-

west of Edinburgh. Strathaven and Kilbride are small towns near Hamilton; the former has been long noted for its veal. There is a number of villages in the vicinity of Glasgow, which, by their situation, belong to that city, and several of considerable extent, in different parts of the county. Among the latter may be mentioned, Crawford, Carnwath, Airdrie, Douglas, Leadhills, Wilsontown, and New Lanark. At New Lanark, there is the largest establishment for cotton spinning in Scotland. Mr Owen, whose arrangements for the comfort and instruction of his people have been eminently successful, is the principal proprietor. The cotton-manufacture, the iron-works, and the collieries, give employment to the greater part of the inhabitants of Lanarkshire. Every great establishment has a considerable village in the neighbourhood, where the workmen reside.

The county of Lanark sends to Parliament one Representative member, who is chosen by about 100 freeholders; tion, &c. and its three royal burghs have a share in the election of two members more; Glasgow and Rutherglen being joined with Renfrew and Dunbarton, and Lanark with Selkirk, Peebles, and Linlithgow. It has one Sheriff-depute, whose jurisdiction extends over all the county, and three substitutes, at Lanark, Glasgow, and Hamilton. Lanarkshire contains 47 parishes, of which 11 belong to the Presbytery of Lanark, 14 to that of Hamilton, and 13 to that of Glasgow, all in the Synod of Glasgow and Ayr; and 9 to the Presbytery of Biggar, in the Synod of Lothian and Tweeddale. The increase of the population has been uncommonly rapid, particularly that of the city of Glasgow. The following tables exhibit an abstract of the census of 1800 and 1811.

See Naismyth's *General View of the Agriculture of Clydesdale—Beauties of Scotland*, Vol. III.—The *General Report of Scotland*—and Playfair's *Account of Scotland*, Vol. I. (A.)

Lancashire.	LANCASHIRE , a great commercial and manufacturing county in the north-west of England.	but towards their base, and in the vallies which they form, it is for the most part of the nature of holme.
Situation.	This district, which is situated between 53° 23' and 54° 24' north lat. and between 2° 18' and 3° 7' west long. has Cumberland and Westmoreland on the north-east and north, Yorkshire on the east, Cheshire on the south, and the Irish Sea on the west. Its extreme length is about 74 miles, and its greatest breadth 44½, but the boundaries being very irregular, its outline is about 342 miles, which comprises an area of 1765 square miles, or 1,129,600 acres. Lancashire forms part of the northern circuit, is situated within the province of York, and diocese of Chester, and divided into 61 parishes. The other divisions are hundreds, of which there are six, namely, Lonsdale on the north, Amounderness, Blackburn, and Leyland in the middle, and Salford and West Derby on the south. Most of these are again popularly subdivided, according to their relative situation, or the names of their towns.	Loam and clay of various degrees of consistence prevail on the flat grounds, with portions of sand, gravel, and moss; and on the banks of the rivers, and at their estuaries, there are large tracts of an alluvial description. The under stratum of the heathy grounds is sandstone or freestone of different colours; a blue rock, popularly called whinstone, is more common in the Fell tracts of Furness. Limestone prevails on the north-west, and towards the eastern boundaries. This and the freestone rock occasionally come in contact with one another in a very remarkable manner, a striking instance of which occurs near the town of Chipping, at the termination of the high ridge of Longridge Fell. In some places towards the eastern border, coal approaches so near the surface, as to constitute the substratum of the soil, and may be seen cropping out at Townley Park, and on the rising grounds on both sides. Marl is frequently found below the soil in the low grounds, and also under the mosses. Much of the vale land consists of rich pastures and meadows; what part of it is under tillage is very productive, and in many instances of a quality to yield turnips and other green crops, as well as grain. A strong clayey loam, however, appears to be the predominant soil throughout the low grounds on the south and west, which, with the wetness of the climate, renders cultivation more difficult and hazardous, than in many other districts.
Extent.		
Divisions.		
Form and Surface.	The greater part of this county, from Rossall Point, on the north, to the Mersey, on the south, except where it is indented by the estuary of the Ribble on the west, lies tolerably compact in the form of an irregular square. To the north of Rossall Point, till it meets the county of Westmoreland, it is very narrow, with a sinuous boundary on all sides; and to the north-east there is a considerable tract called Furness, separated from the rest by extensive sands, where the river Ken, from Westmoreland, discharges itself into the Bay of Morecombe. Opposite the south point of Furness is the island Walney, and other seven, of which the largest is Old Barrow. On the north-east and north much of the surface is occupied with hills and moors, particularly in Furness, where the highest grounds have the name of <i>Fells</i> ; and also on the east, where it is bounded by Yorkshire; but the south and west quarters spread out for the most part into low and fertile tracts, though not without being interrupted by pretty large fields of moss. Chat-moss, near Worsley, and Pilling-moss, farther to the north, are the most extensive, but many other though smaller tracts occur in various parts. Along the coast there is also a considerable extent of sandy marsh-land, particularly towards the north, near Lancaster and Warton, at the estuaries of the Leven and Duddon, in the north-east or Furness district, and about the banks of the island of Walney.	The principal mineral substances are coal, copper, lead, and iron. The first, and in a manufacturing district by far the most important of these, is in great abundance in several parts of the county. The great coal tract commences below Prescott on the south, and, crossing the county in a north-east direction, passes into Yorkshire; but coal abounds farther to the south-east, near Manchester, and also to the north above Lancaster. Its quality, as well as the thickness of the beds, and the depth at which it is wrought, has considerable diversity; but it is chiefly of a bituminous description. Cannel coal is found near Wigan, and at other places, and sometimes in contact with the black coal, or a little mixed with it, as at the pits near Layton-hall. Copper is met with in the rough barren mountains, towards the northern extremity of the high Furness, or Fell-district, particularly at Coniston, Muckle Gill, and Hartriggs; but has not been found to the south of Lancaster Sands in such quantities as to be wrought with advantage. Lead occurs towards the north and north-east parts of the county, but in no great quantity. Iron is wrought to the north of Lancaster Sands, in the liberty of Furness. Though found in other quarters, it is not in much abundance, so as to make the working of it profitable. In the northern part of the high Furness tract quarries of blue slate have been opened. Sandstone is wrought in most parts of the county south of the Sands, and limestone, though it is found also in the Furness district, is most abundant on the Lancaster side. The main tracts of this rock are in the northern divisions above Lancaster, and near Chipping and Clitheroe, towards the borders of Yorkshire. More to the
Climate.	The climate of Lancashire is chiefly distinguished for its humidity. According to a register kept at Liverpool from 1784 to 1792, the least quantity of rain yearly was 24½ inches in 1788, and the greatest 54½ in 1792. At Lancaster, in the latter year, the quantity of rain was nearly 66 inches. Four inches have been known to fall in the course of a night. The mean heat at Lancaster, from 1784 to 1790, was 1° 8'. The prevailing winds are from the south, south-west, and north-east. As fogs are not frequent, nor the stagnant waters of any considerable extent, the climate is not insalubrious.	The great coal tract commences below Prescott on the south, and, crossing the county in a north-east direction, passes into Yorkshire; but coal abounds farther to the south-east, near Manchester, and also to the north above Lancaster. Its quality, as well as the thickness of the beds, and the depth at which it is wrought, has considerable diversity; but it is chiefly of a bituminous description. Cannel coal is found near Wigan, and at other places, and sometimes in contact with the black coal, or a little mixed with it, as at the pits near Layton-hall. Copper is met with in the rough barren mountains, towards the northern extremity of the high Furness, or Fell-district, particularly at Coniston, Muckle Gill, and Hartriggs; but has not been found to the south of Lancaster Sands in such quantities as to be wrought with advantage. Lead occurs towards the north and north-east parts of the county, but in no great quantity. Iron is wrought to the north of Lancaster Sands, in the liberty of Furness. Though found in other quarters, it is not in much abundance, so as to make the working of it profitable. In the northern part of the high Furness tract quarries of blue slate have been opened. Sandstone is wrought in most parts of the county south of the Sands, and limestone, though it is found also in the Furness district, is most abundant on the Lancaster side. The main tracts of this rock are in the northern divisions above Lancaster, and near Chipping and Clitheroe, towards the borders of Yorkshire. More to the
Soils.	The soils of this extensive district are necessarily various. The higher grounds, covered with heath and broken with rocks, have a sterile moorish soil;	More to the

Lancashire. south, that is, throughout the larger and more valuable portion of the county, it occurs but seldom, and not to a great extent.

Waters. Lancashire is naturally well supplied with waters, of which its inhabitants have industriously availed themselves in their manufacturing establishments, and in facilitating the transport of their products of all kinds. The principal rivers are the Mersey, the Irwell, the Ribble, and the Loyne or Lune. The Mersey, after receiving the Etherow and the Goyt from Cheshire, and the Tame from Yorkshire, becomes a large river at the town of Stockport, and after a winding course between this county and Cheshire, enters the Irish Sea a little below the town of Liverpool. By means of an artificial cut, it has been made navigable for vessels of 60 or 70 tons from Liverpool to the mouth of the Irwell, up which river the navigation is continued to Manchester.

Irwell. The Irwell, which has its source among the hilly ranges to the south of Haslingden, also receives several streams, and flowing through a part of Manchester, where it is advantageously employed by the different manufactories, especially those of spinning, dyeing, and calico-printing, falls into the Mersey a little below Flinton. The Ribble is a large river which intersects the county from east to west. It enters Lancashire from Yorkshire, above the town of Clitheroe, and flowing through the beautiful vale of Ribblesdale, joins the Irish Sea a little below the town of Preston, to which it is navigable for small vessels. The Loyne or Lune, also a large river, has its source in the fells of Westmoreland, and comes into Lancashire a little below Kirkby Lonsdale, and passing by the town of Lancaster, afterwards expands into a broad estuary, and empties itself into the Irish Sea. The Alt, the Douglas, the Wyer, the Winster, the Leven, the Crake, and the Dudden, are also considerable streams; and many others, though in a general description not worthy of notice for their size, afford the most important facilities to the manufactories established on their courses. There are several pieces of water in the county, known by the name of lakes, waters, meres, and tarns. Of these the most considerable is Coniston lake, or Thurston water, and Esthwaite water, both in Furness. With these may be mentioned the lake of Windermere, which, though not properly belonging to Lancashire, enters it by its southern point, and forms its boundary for eight or ten miles. Mineral springs have been found at Cartmel, Flukeborough, Wigan, Latham-house, near Ormskirk, and other places.

Of the canals by which a great part of this county is traversed in almost every direction, it would be difficult to give an intelligible description without references to a map, and the limits of this article admit only of noticing them very generally. The great importance of an interior communication by water had been recognized in this quarter a considerable time before any attempt was made to form one entirely artificial. The first object was to render some of the rivers navigable, as in the instance of the Mersey and Irwell, already mentioned, to effect which acts of Parliament were obtained in 1719 and 1720. But the droughts and tides which affect the navigation

of these and other rivers, have been found to occasion so much inconvenience, that more recently a preference has been given to channels of communication formed wholly by human labour. The first work of this description in Lancashire, and probably in England, was the Sankey canal, from the Mersey to near St Helen's, which, including its branches, extends nearly twelve miles. It was finished about sixty years ago. Besides this canal, the county is intersected by nine others, four of which communicate with the populous town of Manchester. Of these we can only notice the more considerable. The Duke of Bridgewater's Canal, in so far as it belongs to Lancashire, commences in the suburbs of Manchester, and terminates at Pennington, near the town of Leigh. Under the town of Manchester a portion of it passes into arched tunnels, from one of which coals are hoisted up out of the barges below, through a shaft, and delivered into a large coal-yard in the main street. Before it reaches the coal-works at Worsley, it is carried under ground for three quarters of a mile. The Lancaster canal commences at Kirkby Kendal in Westmoreland, and terminates at West Houghton, to the eastward of Wigan, after a course of 75½ miles. The principal object in executing this great work was to open a ready communication between the coal and limestone districts, and between the port of Lancaster and the populous towns on the north and south. It is on an average seven feet deep, and is navigable by boats of 60 tons burden. The Leeds and Liverpool canal is of still greater length. It extends between the towns of Liverpool and Leeds, along a line of 107½ miles, and communicating at the latter place with the Aire, which is navigable to the German Ocean, and at the former with the Mersey, which falls into the Irish Sea; the navigation is thus completed between the eastern and western seas. On this canal flats of 12 tons are employed in the coal trade between Leeds and Wigan, and passage-boats are in constant use between these towns. The other canals, though works of great importance when each is considered separately by itself, are much inferior to those we have mentioned.

A considerable portion of the territory of this county belongs in property to his Majesty, as Duke of Lancaster. The greater part of this consists of what is called *forest lands*, all of which are situated in the most northern parts. It is held in general on leases for thirty years, and yields but an inconsiderable revenue. A few other estates are also of a considerable extent, but, generally speaking, landed property is much subdivided, and hence Lancashire has a greater number of land-owners than any other county in England, Middlesex excepted; many of the estates not affording a rental of L. 200 a year, and not a few being below L. 50.

Lancashire does not excel in its agriculture. Only about a fourth of its surface is computed to be under corn and other tillage crops, the other three-fourths, subject to a deduction for wastes, roads, &c. being chiefly occupied in grazing and for the purposes of the dairy; and it has been estimated that it does not raise corn sufficient for the support of its population for more than three months in the year.

Lancashire. All the different sorts of corn, however, are cultivated, and where the soil is naturally fertile the crops are often abundant; but turnips and other ameliorating crops are not in general use, nor always, where grown to some extent, properly attended to. Potatoes, however, are cultivated not only upon a large scale but with great care and success; this root, with oatmeal, forming the principal food of the working classes. They were introduced into this county from Ireland, and are said to have been cultivated here long before they had found their way into most other parts of England. Lancashire was long noted for its breed of horned cattle, but a variety of other breeds have been introduced, particularly the Holderness, or short-horned, which are preferred to the Lancashire in the milk dairies near the town, and sometimes also in those at some distance, where the principal object is butter. The native breed is the kind more commonly kept for the cheese dairies, farther into the interior. A cow yields, upon an average throughout the year, from eight to twelve quarts of milk daily, or from four to six pounds of butter in the week, or from three to four hundred weight of cheese in the year. A considerable number of good horses are bred and reared, but its sheep stocks are inconsiderable, and seldom of a valuable description. Farms are in general small, and held either on short leases or without any lease at all, so that a tenant has no encouragement to invest capital in the improvement of the soil.

Manufactures and commerce

This district, however, is greatly distinguished by its manufactures and commerce, which afford employment to three-fourths of its crowded population. Of the former, that of cotton, which is here conducted in all its branches on the most extensive scale, has long been the most considerable. The town of Manchester, where it seems to have had its origin in England, is still its principal seat, though several of the other towns, such as Preston, Garstang, Blackburn, Clitheroe, Middleton, Burnley, Wigan, Bury, Bolton, and Ashton, have a considerable share of it, and, indeed, it is more or less spread over the greater part of the county. (See the articles COTTON MANUFACTURE and ENGLAND in this *Supplement*.) At Ravenhead, near Prescott, plate-glass and mirrors are made to a considerable extent; brass, pewter, and copper works, are carried on at Wigan and at St Helen's; Warrington has manufactures of sail-cloth, linens, and checks, with the making of pins and glass, and iron-founderies; and Rochdale and Ashton furnish a variety of the coarser articles of woolen.

From the great extent and variety of its manufactures, it is natural to infer that its commerce must

be upon a scale proportionally extensive, and it is so. Liverpool, as a commercial town, is now perhaps second only to London; and to this rank it has attained from a very low beginning little more than a century ago. In prosperous times, the enterprise of its merchants exchanges the products of British capital and industry with those of almost every climate; and, at all times, it carries on an extensive commerce with America and the West Indies, and with Ireland; to which has been recently added a large share of the East India trade. The ports of Preston, Poulton, Warrington, Ulverston, and Lancaster, the county town, are chiefly employed in the coasting trade.

As a considerable portion of the people of Lancashire are employed in working up goods for a foreign market, the condition of the labouring classes, in particular, is much affected by the changes which occur from time to time in that market, and which it is not always possible to anticipate. They are sometimes in the receipt of wages more than sufficient for their comfortable subsistence, and at other times many are thrown out of employment altogether, and the rest retained at wages confessedly inadequate to their support. This is true in an especial manner of its great staple, the cotton manufacture. From this cause, and perhaps also, owing to the inconsiderate habits and want of foresight, which such fluctuations are apt to engender, the poor-rates of this county amounted, in 1815, to about L. 400,000, whereas, 30 years before, they were little more than L. 50,000.

According to the census of 1811, the population of Lancashire was 828,309, which, taking it as before stated at 1765 square miles, gives for every square mile nearly 470 inhabitants. The number of males was 391,104; of females, 434,205. There were 23,305 families, chiefly employed in agriculture; 114,522 chiefly employed in trade, manufactures, and handicraft; and the families not comprised in these two classes were 24,072.

The returns for Manchester, in 1811, exhibit a population of 98,573; for Liverpool 94,376; and Wigan, Warrington, Oldham, Blackburn, Bolton, Rochdale, Preston, and Lancaster, contained each 10,000 inhabitants and upwards.

This county sends 14 members to Parliament, two for the shire, and two for each of the towns of Liverpool, Newton, Wigan, Preston, Clitheroe, and Lancaster.

See *Beauties of England and Wales*, Vol. IX., Dickson's *General View of the Agriculture of Lancashire*, 1815; and the article LANCASHIRE in the *Encyclopædia*.

(A.)

LANGUAGES.

Languages. **I**N the articles LANGUAGE and PHILOLOGY, of the *Encyclopædia*, a philosophical and critical account of the origin and structure of the most remarkable languages has been given at length, and in detail. The subject will at present be resumed in a point of view more strictly historical, and a classification somewhat more extensive of all the known languages of the ancient world will be attempted; some of the materials being almost necessarily derived from the *Mithridates* of Adelung and Vater, and the publications of Jamieson and of Townsend, together with the criticisms on those works inserted in the *Quarterly Review*.

The study of the affinities of various languages is so far one of the most important of all branches of human knowledge, as it affords, when properly applied, an unerring test of the truth or falsehood of historical evidence, without which it would sometimes be impossible to unravel the mysteries of contradictory testimonies, respecting the relations of the different races of mankind. We have, for example, no traditional evidence in support of any connexion between the ancient Egyptians and the Indians, while, on the other hand, a number of persons, who came with the English army from the East Indies into Egypt, were so strongly impressed with the resemblance of the Egyptian and Indian temples, which appeared even to excite the religious feelings of many of the natives who were among the troops employed, that a very general inclination has arisen from these circumstances, to consider the Egyptian mythology as merely a branch of the Indian. But if the Egyptian people had really been of Indian origin; that is, if the Egyptians and Indians had really been one people, at any later period than that, at which the whole of the Indian and European races were separated from their common stock, the languages of India and of Egypt could not but have exhibited some features of resemblance, which would have preserved the traces of the connexion; while, in fact, there is much less similarity between the Egyptian and the Indian, than between the Indian and the Greek, or the English and the Persian; so that etymology may here be adduced as confirming the evidence, or as justifying the silence, of history; and the resemblance of the mythological representations must be considered as in great measure accidental.

It is, however, only with regard to the languages of the ancient world that we can feel much interest in such an investigation. The American dialects might afford equally extensive subjects of speculation in a metaphysical and critical point of view; but the concerns of barbarians, unconnected and remote from all contact with literature or civilization, and destitute of all historical records, will scarcely be thought to require any great portion of attention from a philosophical inquirer; and there is ample

scope for the employment of all our faculties in the analysis and comparison of the various languages of Europe, Asia, and Africa. If, indeed, an extraordinary exertion of enterprise and industry, which can be expected from a few distinguished individuals only in the course of as many centuries, should make known relations, such as Alexander von Humboldt has appeared to discover, between the American and Asiatic nations, a new field would be opened for the gratification of our curiosity; but it can scarcely be expected that these points of resemblance can be sufficiently numerous, to afford any thing like demonstrative evidence, until the whole subject has been much more deeply and repeatedly discussed. In the mean time, a very brief enumeration of the names of the American languages is all that can be required, on an occasion like the present; except the insulated though interesting remark, that the countries separated by Behring's Straits exhibit, as might indeed be expected, strong resemblances, in some of their languages.

Of language in general this essay is not intended to treat, but merely of languages as they are distinct from each other. It is not, however, very easy to say what the definition ought to be that should constitute a separate language; but it seems most natural to call those languages distinct, of which the one cannot be understood by common persons in the habit of speaking the other, so that an interpreter would be required for communication between persons of the respective nations. Still, however, it may remain doubtful whether the Danes and the Swedes could not, in general, understand each other tolerably well, and whether the Scottish Highlanders and the Irish would be able to drink their whisky together without an interpreter; nor is it possible to say, if the twenty ways of pronouncing the sounds, belonging to the Chinese characters, ought or ought not to be considered as so many languages or dialects, though they would render all oral intercourse between the persons so speaking the language actually impracticable. But, whether we call such variations different languages, or different dialects, or merely different pronunciations of the same dialect, it is obvious that they ought all to be noticed in a complete history of languages; and, at the same time, that the languages so nearly allied must stand next to each other in a systematical order; the perfection of which would be, to place the nearest together those languages, in which the number of coincidences in the signification of words, throughout the language, are the most numerous.

It has sometimes been imagined, that all languages in existence present something like a trace of having been deduced from a common origin; and it would be difficult to confute this opinion by very positive evidence, unless every separate language had been very completely analysed and examined by a person

Languages. well acquainted with a variety of other languages, with which it might be compared. But, without such an examination, the opinion must remain conjectural only, and no more admissible as demonstrated, than the opinion of some empirics, that there is only one disease, and that the only remedy for it is brandy. In an essay on probabilities, lately published in the *Philosophical Transactions*, Dr Young has remarked, that "nothing whatever could be inferred, with respect to the relation of two languages, from the coincidence of the sense of any single word in both of them;" that is, supposing the same simple and limited combinations of sounds to occur in both, but to be applied accidentally to the same number of objects, without any common links of connexion; "and that the odds would only be three to one against the agreement of two words; but if three words appeared to be identical, it would be more than ten to one that they must be derived, in both cases, from some parent language, or introduced in some other manner," from a common source; "six words would give near 1700 chances to one, and eight near 100,000; so that, in these last cases, the evidence would be little short of absolute certainty."

The author of the *Review of Mithridates* observes, that, setting out from the establishment of a certain number of separate languages as species, "we may proceed to comprehend, in the description of one family, such as have more coincidences with each other than diversities, and to refer to the same class such families as exhibit any coincidences at all that are not fortuitous, imitative," that is, from onomatopœia, "or adoptive. In order, however, to avoid too great a number of classes, which would arise from an inadequate comparison of languages imperfectly known, it may be proper, in some cases, to adopt a geographical distinction, as sufficient to define the limits of a class, or to assist in its subdivision into orders. We are thus obliged to employ an arrangement of a mixed nature;" and, in fact, the tests of affinity here proposed depend so much on the progress of our knowledge, in the study of each language, that the results must unavoidably be liable to great uncertainty and fluctuation; so that we can reasonably expect nothing more than an approximation to an arrangement completely methodical.

"If," continues the Reviewer, "the resemblance or identity of a single word, in two languages, supposed to be exempt from the effects of all later intercourse, were to be esteemed a sufficient proof of their having been derived from a common stock, it would follow, that more than half the languages of the universe would exhibit traces of such a connexion, in whatever order we might pursue the comparison. Thus we find in a very great number, and perhaps in a majority of known languages, that the sound of the vowel *a*, with a labial consonant, is employed for the name of *Father*; and if this be supposed to be something like an onomatopœia, or an application of the first sounds which an infant naturally utters, the same reason cannot possibly be assigned for the still more general occurrence of the combination *nm* in the term *Name*, which is by no means likely to have originated from any natural association of this kind. But neither these points of resemblance,

nor any other that can be assigned, are absolutely universal; for besides the numberless varieties referable more or less immediately to *Abba*, *Father*, we have at least twenty different and independent terms for the same relation in the old world; *Tia*, *Isha*, *Plar*, *Hair*, *Rama*, *Diam*, *Bina*, *Kettem*, *Assanulagi*, *Medua*, *Thewes*, *Sünk*, *Iot*, *Anathien*, *Messce*, *Indaa*, *Nu*, *Nam*, *Monung*, *Dengabey*, *Ray*, *Tikkoh*, and *On*; and about as many for *Name*, besides those languages, in which the version of an abstract term of this kind is less likely to have been ascertained; *Ming*, *Tren*, *Diant*, *Sheu*, *Hessara*, *Shem*, *Tsarship*, *Ad*, *Nipta*, *Lüm*, *Sacheli*, *Assia*, *Wasta*, *Ngala*, *Tarra*, *Sünna*, *Ran*, *Hhili*, *Ding*, *Dhai*, and *Inghara*. "At the same time, therefore, that we venerate the traces of our common descent from a single pair, wherever they are still perceptible, we must not expect to find them in all existing languages without exception; and an *Etymologicon Universale*, considered as intended to establish such a perfect community of derivation, can only be regarded as a visionary undertaking. Nor must we neglect to unite, in some common arrangement of classification, those languages which have the words here specified, or any other radical words, in common, as incomparably more related to each other than the Chinese to the Cantabrian, or the Irish to the Hottentot."

"The gradations, by which a language is likely to vary in a given time, seem to be in some measure dependent on the degree of cultivation of the language and of the civilization of the people employing it. From Homer to the Byzantine historians, the Greek language remained essentially the same for 2000 years; the German has varied but little for 1500; and even the English, notwithstanding its mixture with French and Latin, has altered but three radical words, out of the fifty four which constitute the Lord's Prayer, in the same period. On the other hand, a few barbarians in the neighbourhood of Mount Caucasus and of the Caspian Sea, of modern origin, and ignorant of the art of writing, are divided into more nations speaking peculiar languages, radically different from each other, than the whole of civilized Europe. In such cases, little light can be thrown upon history by etymological researches, while, with regard to more cultivated nations, we obtain, from the examination of their languages, historical evidence of such a nature, as it is scarcely possible for either accident or design to have falsified."

According to the supposition of Professor Adelung, it seems not improbable that Tibet, on the east of Cashmir, may "have been the habitation of Adam immediately after his fall, and the country occupied by the descendants of Cain. In Tibet, and in the countries immediately beyond it, the languages of at least 150 millions of people are still principally MONOSYLLABIC, and from this peculiarity, as well as from the singular simplicity of their structure, they are supposed to constitute the most ancient class of existing languages, though it must be confessed that much of Adelung's reasoning on this subject is extremely inconclusive." Mr Townsend remarks very judiciously, that one of the canons of Rüdbeck is by no means admissible. "He states,

languages. that a language, which has numerous monosyllabic expressions, is a parent language. The English has more than 3700 monosyllabic expressions, and the Chinese has none but such; yet neither of them is, for that reason, to be considered as a parent language. Certain it is, that all languages, by abbreviations, have a tendency to become monosyllabic, and therefore a language, which abounds in monosyllables, is ancient, and these commonly are the most antiquated parts of every language. New compounds are incessantly created. These are abbreviated, and in process of time become monosyllabic. In deriving, therefore, a word in one language, from its correspondent expression in some other language, we must ever bear in mind, that, unless in the formation of new compounds, the least abbreviated is commonly the parent, and the most abbreviated its offspring. "Would it be possible for any one to persuade us that *Colaphus* was derived from *Cuff*, or *Blasphe'me* from *Blame*?" "A similar instance," says the Reviewer, "might be found in *Trachelos* and *Hals* of the Greeks and Germans; for certainly *Hals* is more like *Trachelos* than like *Collum*."

The Chinese, however, which is the principal, and probably the most ancient of the monosyllabic languages, is distinguished from almost all others by a more marked peculiarity, which is, that its written characters, instead of depicting sounds, are the immediate symbols of the objects or ideas, and are even imperfectly represented by the sounds, whatever difference of accent or tone may be exhibited by the most refined speaker; as indeed it may happen accidentally in our own language, that we may be at a loss to explain, without circumlocution, whether we mean to say *Son* or *Sun*; *Beer* or *Bier*; *Bear* or *Bare*; *Yon*, *Iwe*, *Yem*, or *U*; but in the Chinese the real cause of this essential characteristic appears to be, that the symbol was in fact originally intended as a hieroglyphic or picture of the object, though the resemblance, coarse as it probably was at first, has been generally altogether lost by the modifications which the character has conventionally undergone. And in this point of view the Chinese would require to be classed with the old Egyptian only, since we know of no other language which was habitually expressed in hieroglyphics and their immediate derivatives. It is not at all uncommon for the same sound in Coptic, as in Chinese, to have four or five senses all essentially different; as may easily be observed in turning over a dictionary; *noou*, for instance, means *Bad*, and *Them*, and a *Shower*, in two verses of St Matthew, v. 45, 46, and perhaps several other things.

Another ancient and extensive class of languages, united by a greater number of resemblances than can well be altogether accidental, may be denominated the INDOEUROPEAN, comprehending the Indian, the West Asiatic, and almost all the European languages. If we chose to assign a geographical situation to the common parent of this class, we should place it to the south and west of the supposed origin of the human race; leaving the north for our third class, which we can only define as including all the Asiatic and European languages not be-

longing to the two former; which may be called Atactic, or, perhaps, without much impropriety, TATARIC; and which may be subdivided into five orders, *Sporadic*, *Caucasian*, *Tartarian*, *Siberian*, and *Insular*. The AFRICAN and AMERICAN languages will constitute a fourth and a fifth class, sufficiently distinct from all the rest, but not intended to be considered as any otherwise united among themselves, than by their geographical situation. There is indeed little doubt, that some of the languages here called Tataric are essentially allied to others, which are referred to the Indoeuropean class; but they have been too little investigated, to allow us to make the selection that would be required for completing the classification.

The following tables are copied, with some considerable additions, from the *Quarterly Review*, where they stand as extracted, in great measure, from Adelung's *Mithridates*. The words *Heaven* and *Earth* are chosen as specimens, because they seem to be known in a greater number of languages than any others, except the name of *Father*, which is supposed to exhibit, in some cases, a fallacious similarity. The German orthography has been principally employed, except in such languages as are usually written in the Roman characters, the pronunciation of the consonants being more uniform than in English, and that of the vowels differing little from the Italian.

(The Hottentots have three particular clicking sounds, made by withdrawing the tongue from the teeth, the fore part, and the back part of the palate: they are respectively denoted by T', T'', and T'''. the two first appear to resemble the sounds sometimes used to express a trifling vexation, and to make a horse go on, or to call to poultry.)

These tables will at least serve, notwithstanding some imperfections and uncertainties, as a convenient synopsis for facilitating the reference to a brief sketch of the history of the different families of languages.

1. The strongest proof of the great antiquity of the Chinese language appears to be the great simplicity of its structure, and the want of those abbreviations and conventional implications which have been sometimes called the wings of languages. It is natural that, in attempting to express ideas at once by characters, the rude pictures of material objects should first have been principally, if not exclusively traced; thus the Egyptians had ☉,) for the sun and moon, and 1 for a country or field, and the

Chinese have still E 𠄎, 田 for these objects

respectively, the characters having been made square instead of round, which some of them were in their more ancient forms. The Egyptians represented a man by a figure kneeling, and stretching out his hand.

or in the enchorial character, thus 𠄎. (See the ar-

ticle EGYPT, Pl. LXXV. n. 79.) The Chinese figure may originally have been of the same form, but at present is more like a pair of legs only, 𠄎, while a

dog seems to have three or four legs; 𠄎, or 𠄎.

A thousand, according to Mr Jomard's ingenious conjecture, was copied from the lotus, with its seed vessel, having a great multitude of seeds, and the Chinese

𠄎 is certainly not altogether unlike the Egyptian 𠄎

(n. 202), nor is the character for light 光, which

seems intended to represent a radiant body, altoge-

ther different from the 𠄎 or 𠄎 so often found

among the hieroglyphics of Egypt, although it is not easy to believe, with Mr Palin, that the manuscripts found with the mummies agree precisely with a Chinese version of the Psalms of David, character for character. The successive introduction of figurative expressions and characters may easily be imagined, but it would be useless to enter at present into further details of this kind on grounds almost entirely speculative. The Chinese are said to have been, in the ninth century, a race of people resembling the Arabs; their physiognomy was contaminated, in the thirteenth and fourteenth, by a mixture with their conquerors, the Mongols; but their language remained unaltered. The dialect of Tonkin is sometimes called the language of Anam, and the Guan; on occasions of state they use the Chinese character, but more commonly a character of their own, probably resembling that of the Siamese. Dr Leyden observes, that at least twenty different nations employ the Chinese characters, though they read them quite differently, and he considers the Cochinchinese, the Cantonese, and the Japanese, as all essentially different from the Mandarin Chinese, though they have all some words in common. He gives us, as the names of the dialects of Chinese, constituting almost as many separate languages, 1, Kong, spoken at Canton; 2, Way; 3, Nam; 4, Chéu; 5, Séu; 6, Lú; 7, Lám; 8, Kuum, or Mandarin; 9, Siu, 10, Kunng; 11, Hyong sar, spoken at Macao; 12, San takk, 13, Nam kái; 14, Pún ngi; 15, Tong khán; 16, Fo khun; or Chinchow. There is also a language spoken by the Quan tó, between Tonkin and China, a people who consider themselves as more ancient than their neighbours. Notwithstanding, however, all this supposed diversity, we may trace a considerable resemblance in the spoken language, even as far as Corea. In all these dialects, the conversation is a sort of recitative, and the different notes give distinct meanings to the words; as, in fact, we distinguish in English the sense of M? from M! or simply M.; tones perfectly understood, though never written. The Chinese are without the sound of the letter r, and several other sounds common in Europe; the only way in which they express foreign words is, by putting together the characters of the nearest import, with a symbol of pronunciation annexed to them; thus, for Christus and Cardinalis they are obliged to write Kí lu su tu su and Kia ul fí na li su, with a mouth annexed to them. The names of places are generally distinguished by a square inclosing the characters which express them, and the names of men, in some books, by a line drawn on one side of the characters only. In this there seems to be a distant analogy to the ring which incloses proper names in the Egyptian inscriptions, but the names of places were not distinguished in this manner by the Egyptians. The dialects of Cambodia and Laos have received some mixture of Malayan from their neighbours;

Languages. in writing the former of these, sometimes called *K'hôhmen*, according to Dr Leyden, the Bali, or old Sanscrit character, is employed; and the latter has some analogy with the Siamese; indeed, both the Siamese and the Avanesse are disposed to derive themselves from Laos. It may be seen, from the specimens exhibited in the article *PALEOLOGY* of the *Encyclopedia*, b. 125, that at least some of the Chinese dialects have sounds agreeing in several instances with European words of the same import; but the agreement is scarcely precise enough to justify our inferring from it an original connexion between the languages.

2. The language of SIAM resembles the Chinese in its simplicity and metaphorical structure, though not so decidedly monosyllabic. It is obvious, however, that the distinction of monosyllabic and polysyllabic could not, in very ancient times, have been so positively laid down as at present, since it was usual, in almost all countries, to write the words contiguous to each other, in a continued series, without any divisions between them; and, even in modern printing, there is a happy invention, which often restores this agreeable obscurity, under the name of a hyphen, by the use of which we avoid the difficulty of determining whether we wish to employ one word or several. The Siamese call themselves *T'hay*; and a part of their country is distinguished by the appellation *Tai hai*, or Great *T'hay*. The numerals resemble the Mandarin Chinese; several words of the language are borrowed from the Bali; it is written in an alphabetical character, which is said to be complicated and refined.

3. The AVANESE or *Burmanish* has also borrowed some polysyllabic words from the Bali, and is written in a peculiar alphabetical character. It must be considered as an era in the history of this country that its Emperor has employed Mr Felix Carey, at his own expense, to establish a printing press at Ava, his metropolis, for printing a translation of the Scriptures in Burmanish. A dialect, spoken in the district called Tanengrari, is said to be of greater antiquity. The *Môn* or *Peguan* is called by Dr Leyden a distinct original language; but it is written in the Avanesse character, and Adelung's specimen scarcely differs at all from the Burmanish. The language of Arakan and Rashaan is called *Rukheng*; it contains a number of words from the Bali, many of them converted into monosyllables by an imperfect pronunciation. Dr Leyden considers it as the connecting link between the mono-syllabic and the polysyllabic languages, and he calls it an original language, notwithstanding its acknowledged derivation from its neighbours. It employs the Devanagiri alphabet, including the letter *ṛ*. Out of 50 words of *Rukheng*, quoted by Buchanan, the seven which are not Burman are only varieties of pronunciation. The *Kiayn* or *Kol'* and the *Kuks*, north-east of Cuatigong, are mentioned as neighbouring tribes, speaking languages almost entirely different from the *Rukheng*. We find, in Mr Buchanan's paper, some specimens of the languages of the Burma empire, which it is difficult to distribute methodically, without a further knowledge of their pec-

culiar characters, but some of which may, without Languages
impropriety, be introduced here.

4. The language of TIBET, or the Tangutish, has some words in common with the Chinese, but is less simple in its structure. It is at least as ancient as the religion of the country, which is nearly coeval with Christianity. Its character is well known to be alphabetical, from the title of the learned work of *Father Georgi* on the subject.

5. The *Indoeuropean* languages have been referred to a single class, because every one of them has too great a number of coincidences with some of the others, to be considered as merely accidental, and many of them in terms relating to objects of such a nature, that they must necessarily have been, in both of the languages compared, rather original than adoptive. The *SANSCRIT*, which is confessedly the parent language of India, may easily be shown to be intimately connected with the Greek, the Latin and the German, although it is a great exaggeration to assert any thing like its complete identity with either of these languages. Thus we find, within the compass of the Lord's Prayer only, *Pida*, *Pitir*, among the Sanscrit terms for *Father*, Gr. *Pater* *Nama*, or *Namadheya* for *Name*, Gr. *Onoma*, (*Monamati*; *Radsham*, *Kingdom*, Lat. *Regnum* from *Rego*, *Manasam*, *Will*, like the Greek *Menuo*, and the Latin *Mens*; *Stira*, *Earth*, Gr. *Era*, whence perhaps the Latin *Terra*; and *Danin*, or *Devanagiri* *Dia*, *Day*, Lat. *Dies*. There are also some singular resemblances of declension and conjugation between the Sanscrit and the Greek, as *Dodami*, *Dodasti*, *Dodati*; in old Greek *Didomi*, *Didosti*, *Didoti*. In a tablet of the date 23 B. C. we find *Kritico* for a *Judge*, Gr. *Crites*, *Criticos*. In Mr Townsend's work we also find some well selected instances of resemblance between the Sanscrit and other languages; thus *Bhru*, is *Brow*; *Pota*, a *Boat*; *Bad*, a *Bath*; Germ. *Bad*; *Dhara*, *Terra*; *Nava*, *No- vus*; *Nakta*, *Nocte*, *Night*; *Pad*, *Foot*, *Patie*;

LANGUAGES.

Languages. *Prathama* or *Protoma*, first, whence we may deduce both the Greek *protos*, and the Latin *primus*; and *Upadesaca*, *Didasco*, *Docco*, and *Disco*. We have also *Vayajan*, wind, in Russian *Vieyanie*; and *Vidhava*, widow, Latin, *Vidua*, German, *Wittwe*, Russian, *Vdova*. The *vr* of the plural verb is found in the Sanscrit *Bhavanti*, they are, *Dadanti*, they give. Sir William Jones and many others have attributed to some of the works, which are still extant in Sanscrit, an antiquity of four or five thousand years; but Professor Adelung denies the validity of any of the arguments, which have been adduced, in favour of a date at all approaching to this.

The Sanscrit, even in its earliest state, can scarcely have been altogether uniform throughout all the countries in which it was spoken, and it has degenerated by degrees into a great diversity of modern dialects: the term signifies learned, or polished. Beyond the Ganges, it is called *Bali* or *Magudha*, which the missionaries say "scarcely" differs from Sanscrit; the term *Magudha* is said to mean mixed or irregular. In Siam the Sanscrit is still the language of elegant literature; and it is often employed throughout India, with some little difference of construction, under the name of *Devanagara*, the divine language. The *Prakrit* is rather a vague term, meaning, according to Mr Colebrooke, common or vulgar, but it is also applied to the language of the sacred books of the "Jainas." We find in a little publication, entitled, *A Brief View of the Baptist Missions and Translations*, some useful information respecting the Indian languages and dialects, into a great number of which these laborious and disinterested persons have made or procured translations of the whole of the Scriptures, which they have printed at Serampore near Calcutta. The dialects, which they enumerate, are principally arranged in a geographical order; and beginning with those which are spoken towards the middle of India, as the pure Sanscrit and its least modified dialects, we may place next to them the languages of the countries bordering on the monosyllabic nations, towards the North and East; we have here the dialects of *Nepal*, *Assam*, or *Thumiya*, *Tiperah*, and *Kassai*, of which little more is known than that translations into the first two have been already executed: the *Bengalee* is spoken in and about Calcutta: the *Hindee* or *Hinduce* is spoken about Agra; it is printed in the *Devanagri* character, the font of which contains more than 800 varieties of letters and their combinations; the *Urdu* or *Oordoo* is a subdialect of the Hindee, as well as the *Brijbassa*, which is nearer to the Sanscrit than some other dialects: the *Jypura* is mentioned as another language, belonging to the same neighbourhood: the *Hindustance* is spoken in Hindustan Proper, or Lower Hindustan; the missionaries say it is "diametrically different" from the Hindee: the *Mobrs* or "Mongol Indostanish" seems to belong to this country, being mixed with a good deal of Persian and Arabic, unless it be rather referable to the Hindee: the dialects of *Udaipura*, *Benares*, and *Munipura*, are also called separate languages: the *Goandee* is spoken at Nagpore, in the Mahratta country: further east is *Orissa* or *Uriya*, the language of which is printed in a character requiring

300 different types: the *Telug* or *Wurug* is spoken about Cuddalore and Madras: the *Telinga* further west: the *Carnatic* has a peculiar language, besides the *Tamul*, which is spoken from Paleacate, near Madras, to Cape Comorin, and the *Marwa*, which appears to belong to a part of this country. About Cochin in Travancore we have the *Maleium*: further north the languages of *Malabar*, *Kanara*, and of the *Decan*; the dialect of Malabar is of considerable antiquity, being found in two copper tablets as old as the eighth or ninth century; then comes the *Mekuna*, about Bombay: the *Mahratta* is further inland: the *Guzurat* on the coast: and beyond the Indus the *Beloshee* in Belochistan: north of this we find the *Afghan* or *Pushtu* language, which contains more Hebrew words than any of its neighbours; the people are said to have come from the north, about 2000 years ago, and, according to a Persian tradition, to be descended from King Saul: indeed, the language stands somewhat more correctly under the Median family in the *Mithridates*, but since it forms the connecting link between the two families, it might perhaps be as conveniently arranged among the more numerous species of the Sanscrit; it is written in the Arabic character, with some additional letters for expressing the Sanscrit sounds. The language of *Multan*, north of *Sindh*, has about one tenth of Persian mixed with it. The *Gipsies* were certainly expelled from some part of India by the cruelties of Timur Leng, about 1400; and they were probably some of the *Zingans*, in the neighbourhood of *Multan*; their language having a great number of coincidences with that of *Multan*, and being still more manifestly a dialect of the Sanscrit, although they have adopted many European, and especially Slavonian words. When they first appeared in Europe, they were supposed to amount to about half a million; at present they are less numerous.

The *Maldivian* is peculiar to the group of small islands from which it is named; the Baptists have already printed some books in it. The people are said greatly to resemble those of Ceylon. The *Cingalese*, which is spoken in great part of Ceylon, is a mixture of several of the continental dialects; and it has been observed that the proper names in Ceylon mentioned by Ptolemy are of Sanscrit origin. Dr Leyden gives as a proof of the antiquity of the *Malayan*, that the *Temala* of Ptolemy is derived from *Tema*, tin. The connexion of this language with the Sanscrit has not been very universally admitted; and some of those who have studied it most are disposed to consider it as wholly original; but in the purest part of the language, Dr Leyden confesses that there is a considerable resemblance to the *Japanese* and the *Siamese*; the words derived from the Sanscrit he considers as somewhat less numerous amounting however to about 3000, they are generally less like the *Bali* than the Sanscrit, and a still smaller number are borrowed from the Arabic. The character of the monosyllabic languages is in some measure retained. Sir William Jones considered the *Malayan* as a derivative of the Sanscrit; Mr Marsden supposes it to have received its Sanscrit words through *Guzurat*; Dr Leyden rather from Ka-

Languages. *linga* or *Telinga*; and it exhibits some traces of the dialects of *Tamul* and *Maléalam*. Besides these various sources, it is said to have borrowed some of its simplest words from the *Javanese* and the *Bûgis*; and it has become more nearly monosyllabic by dropping the first syllables of some of the words which it has adopted. The *Japanese* is said to be more ancient than the *Malayan*; the empire of *Java* was formerly powerful and flourishing: the ancient language was much like the *Sanscrit*, more so than the *Malayan*, but was written in a peculiar character. Dialects of this language are still spoken in *Bali* and in *Madura*. *Leyden* thinks the *Malays* were derived from *Java*; *Marsden* rather from *Sumatra*: though he allows that there are some reasons for conjecturing that an old *Sanscrit* colony may have settled many hundred years ago in *Java*, and mixed its language with a supposed mother tongue of that Asiatic race.

Of the *Sumatran* dialects, the principal, according to *Dr Leyden*, is the *Batta*, spoken by a people who occupy the centre of the island, and who still, like some other Indian nations, retain the custom of eating their old relations. The language seems to be partly original, and partly connected with the *Malayan*, and other dialects of the neighbouring islands. The *Rijang* is chiefly a mixture of *Batta* and *Malayan*; in the *Lampuhn* or *Lampung*, there is also some *Javanese*. The *Achi* has admitted a still further influx of words belonging to all the *Musliman* jargons of the neighbourhood, especially to that of the *Mapulas* of *Malabar*. There are other dialects of less note in *Néas* and the *Poggy* Islands, most resembling the *Batta*. This language is provided with a peculiar alphabet, which is remarkable for being written from the bottom of the paper upwards, like the *Mexican* hieroglyphics: though the *Battas*, as well as the *Chinese*, sometimes hold their books so as to read horizontally. In *Borneo* there appear to be several dialects, or rather separate languages, two of them, according to *Dr Leyden*, are the *Biaja* and the *Tiaun*. The *Andaman* language is inserted here for want of a better place only, it does not appear to have any connexion with the *Sanscrit*, and may possibly be found to be more like that of *Madagascar*: the people seem to belong to the *Papuas*, a distinct original race, according to *Dr Leyden*, black, and with woolly hair.

Besides the numerous translations into languages of the *Indoeuropean* class, the *Baptist Missionaries* have also printed some *Armenian* and *Persian* works at the indefatigable press of *Serampore*, which is supplied by a letter foundery and a paper mill, belonging to the same establishment, enabling them to execute the whole business at less than half the expense of *European* books of the same magnitude. The little pamphlet, already quoted, contains also specimens of the characters of the *Sanscrit*, *Assam*, *Bengalee*, *Mahratta*, *Sikh*, and *Cashmirian*, which somewhat resemble each other in the square form of their characters, as well as of the *Burman*, *Orissa*, *Telinga*, and *Cingalee*, which have a more rounded and flourished appearance; of the *Tamul*, which looks a little like *Armenian*; of the *Afghan* and the *Persian* used in *India*; and of the *Chinese*, both as

printed from blocks, and from the moveable metal *Languages*-types which have been cast at *Serampore*.

6. The connexion of the *Median* family with the *Sanscrit* on one side, and with the *Greek* and *German* on the other, is sufficiently proved by the words *Abitap*, *Zend. Sun*, *Sanscr. Abitaba*; *Dur, Ter*, *Pers. Dour*, *Sanscr. Dura*, *Tiwara*, *Javanese, Turi*, *Gr. Thura*, *Germ. Thir, Ther*; *Dép, Pers. Land* or *Island*, *Sanscr. Dihp*; *Dochtar, Pers. Pothré* *Zend. Daughter*, *Gr. Thigater*, *Germ. Tochter*, *Sanscr. Putri*; *Jaré, Zend. Year*, *Sanscr. Jahran*, *Germ. Jahr*; and *Ishk, Zend. Love*, *Sanscr. Isha*. To this list we may add, from *Dr Leyden*, *Strce*, *Zend. Woman*, *Sanscr. Stri*; *Asté, Zend. He is*, *Sanscr. Asti*, *Gr. Esti*; *Hapté, Zend. Seven*, *Sanscr. Saptah*, *Gr. Hepta*. There are also some coincidences with the *Chaldee*, but the *Median* is certainly not a dialect of the *Chaldee*. *Sir W. Jones* and others have said that the *Zendish* was nearest to the *Sanscrit*, and the *Pehlvi* to the *Chaldee* or *Arabic*. In ancient *Media*, the *Zendish* was the language of the northern, and *Pehlvi*, or *Parthian*, of the southern parts; the word *Pehlvi* or *Pahalevi* is supposed by *Leyden* to have been nearly synonymous with *Pali* or *Bali*, though this is said to be derived from *Bahlika*, an *Indoeuropean* country. The *Zendish* was more particularly appropriated to religious purposes, and the *Pehlvi* had in a great measure superseded it for common use at a very early period. Under the *Sassanides* again, from the third to the seventh century, the use of the *Pehlvi* was discouraged, and the old *Persian* substituted for it. It is said, however, that in the remote parts of the country, about *Shurwan*, some traces of the *Pehlvi* may still be found in existence. The *Zendavesta* of *Zoroaster*, which is still extant in *Zendish*, is supposed to have been written 520 years B. C.; and *Adelung* follows *Anquetil* in asserting its authenticity, even in opposition to the opinion of *Jones* and *Richardson*. These languages have little or no connexion with the *Georgian* and *Armenian*, which have succeeded them in some of the same countries. The old *Persian*, which seems to be much connected with the *Pehlvi*, has remained in use either as a living or as a learned language ever since the time of the *Sassanides*; it was current among the *Persians* when they were conquered by the *Arabs* in the seventh century; and it is the language of the *Shah Nameh* of *Firdusi*, written in the tenth century, as well as of the *Ayeeen Akbery*, of which the date is about 1600. The modern *Persian* became a cultivated language about the year 1000, having received a considerable mixture of *Arabic* and *Turkish* words. The term *Parsée* is commonly applied to a corrupt *Pehlvi*, spoken by the refugee Jew worshippers in *Bombay*.

The *Goths* are said to have inhabited, for some centuries, the countries about the *Black Sea*, and may originally have bordered on *Persia*; from this circumstance, and probably also from the effects of a later irruption of the *Goths* into *Persia*, which is recorded in history, we may easily explain the occurrence of many *Persian* words in *German*, and in the other languages of Northern Europe. *Professor Adelung* has examined more than two hundred

Languages. cases of such resemblances, and has found only one sixth part of them in Anquetil's vocabularies of the more ancient dialects; he has, however, omitted to state what proportion the whole magnitude of these vocabularies bears to that of a complete dictionary of the language. It is well known that an Essay was published a few years since in London, *On the Similarity of the Persian and English Languages*; and a more elaborate work on the relations of the Persian languages, by Mr Le Pileur, has since appeared in Holland. Mr Le Pileur attempts to explain the *is* or *s* of the genitive of the northern languages, by the Persian proposition *ez*, which seems to be synonymous with the Greek and Latin *ex*; but he has not shown that this *ez* ever follows the noun to which it relates.

The *Kurds* speak a corrupt dialect of the Persian; they are probably derived from the Carduchi of the Greeks, who inhabited the Gordian hills. They spread into Persia about the year 1000, and are now situated on the borders of the Persian and Turkish dominions. The language of the *Afghans*, about Candahar, is said to contain about one fourth of Persian, and some Tartarian, besides the Sanscrit which abounds in it.

7. The ARABIAN family is called by the German critics *Semitic*, from Shem the son of Noah, as having been principally spoken by his descendants. Though not intimately connected with the European languages, it is well known to have afforded some words to the Greek and Latin; it has also some in common with the Sanscrit, though apparently fewer than either the Greek or the German. Thus we have *Acer*, Hebr. a *Husbandman*; *Ager*, Lat. a *Field*; *Asther*, a *Star*, Gr. *Aster*; *Bara*, *Buri*, Germ. *Burg*; *Ben*, Hebr. *Son*, Sanscr. *Bun*, *Child*; *Esh*, Hebr. *Eshta*, Chald. *Fire*, Sanscr. *Aster*; and *Ish*, Hebr. *Man*, Sanscr. *Isha*, *Man* or *Lord*. The Hebrew *Ani*, *Anoki*, *I*, has been noticed by Townsend and others as affording an etymology for *Ego* as well as for *Ni* or *Mi* of verbs, for the *Anok* of the Egyptians, and even for the *Ngo* of the Chinese.

The northern nations of this family have sometimes been comprehended under the name *Aramaic*, in contradistinction to the middle, or Canaanitish, and the southern, or Arabian. The Eastern Aramaic, or old *Chaldee*, is very little known; it was the language of a people situated in the north of Mesopotamia, which is now the south of Armenia; a part of them extended themselves further south, and became Babylonians; of whose dialect some traces are said still to exist, about Mosul and Diarbeker. The old Assyrians, between the Tigris and Media, were a colony of the Babylonians, and spoke a language unintelligible to the Jews. (II. Kings, 18.) The western Aramaic has become known, since the Christian era, as the *Syriac*, in which there is an ancient and valuable translation of the *New Testament*. It is still spoken about Edessa and Harrau. The Palmyrene was one of its dialects; the modern *Assyrian* of the Russian Vocabularies appears to be another.

The language of the Canaanites is said, by St Jerom, to have been intermediate between the Hebrew

and the Egyptian. The people are supposed to have come originally from the Persian Gulf; the Philistines, who were found among them, to have emigrated from the Delta to Cyprus, to have been thence expelled by the Phenicians, and to have adopted the language of the Canaanites, when they settled among them. The book of Job is considered as affording some idea of the dialect of Edom; it is well known to contain many Arabisms, besides some other peculiarities. The *Phenician* is only known from a few coins and inscriptions found chiefly in Cyprus and in Malta, and ~~now~~ yet very satisfactorily deciphered, though Akerblad is convinced, by some of them, that it varied but very little from the Hebrew; of its descendant, the *Punic*, or Carthaginian, a specimen is preserved in the speech of Hanno in Plautus, as happily arranged by Bochart; the objection of Adelung, respecting the want of a proper name, appearing to have arisen from a mistake. The last six lines of the text are probably either a repetition of the same speech in the old Lybian of the neighbourhood, or a jargon intended to imitate it.

The *Hebrews* originated among the Chaldeans: Terah, the father of Abraham, having been a native of Ur, or Edessa, beyond the Euphrates; they adopted the language of the Canaanites, among whom they led a nomadic life; till their residence in Egypt, which must probably have had some effect in modifying their language. After that time, however, it appears to have varied but little, in a period of 1000 years, from Moses to Malachi, and this circumstance Adelung considers as so uncommon and improbable, that he is disposed to believe that the writings of Moses must have been modernised, at least as late as the time of Samuel. The old Hebrew became extinct, as a living language, about 500 B. C.; 1000 years afterwards, the Masoretic points were added, to assist in its pronunciation; and this was done in some measure upon the model of the Syrochaldaic, which at that time was still spoken. The Septuagint version, which is much older, supports, in the instances of many of the proper names, the reading indicated by the points, but in about as many others it appears to deviate from that system, and to agree with a mode of pronunciation founded upon the text or principal characters alone. The reading in Greek letters of Origen, in his *Hexapla*, tends, on the whole, very strongly to support the points. The *Chaldee* had superseded the Hebrew at the time of the captivity, and was gradually converted into the *Syrochaldaic*, which is called Hebrew in the New Testament. The Targums, and the Talmud of Babylon, are in the older Chaldee; and a Syrochaldaic translation of the New Testament has been discovered to be still in existence.

The *Samaritan* somewhat resembles the Chaldee; it was formed among the Phenicians and others, who occupied the habitations of the ten tribes, when they were carried into captivity by Salmanassar and Esarhaddon. Its peculiar alphabet is well known as a mere variation of the Hebrew.

The *Rabbinic* dialect was principally formed in the middle ages, among the Spanish Jews, who were chiefly descended from the inhabitants of Jerusalem;

Languages. while those of Germany and Poland were generally Galileans, and spoke a ruder dialect of the Hebrew than the fugitives from the metropolis.

The *Arabs* have been a distinct, and in great measure an independent nation, for more than 3000 years. Some of them were descended from Shem; others, as the Cushites, Canaanites, and Amalekites, from his brother Ham. Their language, as it is found in the Koran, contains some mixture of Indian, Persian, and Abyssinian words. Its grammar was little cultivated until a century or two after the time of Mahomet. It is certainly copious, but its copiousness has been ridiculously exaggerated, and absurdly admired. The best Arabic is spoken by the upper classes in Yemen; in Mecca it is more mixed; in Syria corrupt, and still more so in some parts of Africa. There are dialects which require the assistance of an interpreter to make them intelligible; at the same time, it has been maintained by Aryda, a learned Arab of Syria, in contradiction to Niebuhr, that the Arabic of the Koran is still employed in conversation among the best educated of the people, as well as in correct writing. The Arabs living in houses are called Moors; and those of Africa are the best known under this name. The Mapuls, or Mapulets, of Malabar and Coromandel, are a numerous colony of Arabs, who have been settled there above a thousand years.

The *Ethiopians* are descended from the Cushite Arabs. In the time of Nimrod they conquered Babylon: before that of Moses they emigrated into Africa, and settled in and about Tigri; in Isaiah's time, they seem to have extended to Fez; and at present they occupy Tigri, Amhara, and some neighbouring countries. They became Christians in 325, but retained the initiatory ceremony of the Jews and Mussulmen. The pure or literary Ethiopic is called *Geez*, or *Axumitic*, in contradistinction to the *Amharic*, by which it was superseded as the language of common life in Amhara, about the fourteenth century, although it is still spoken, without much alteration, in some parts of *Tigri*; while, in others, as in *Hauasa*, a different dialect is spoken. The Ethiopic was first particularly made known in Europe by the elaborate publications of Ludolf. Mr Asselin has lately procured a translation of the whole of the *Bible* into the *Amharic*, as it is now spoken at Gondar; it was executed by the old Abyssinian traveller who was known to Bruce and to Sir William Jones, and it is said to be now printing at the expense of some of the British societies.

The *Maltese* is immediately derived from the modern Arabic, without any intervention of the Punic. The island, having been successively subject to the Phaeacians, Phenicians, Greeks, Carthaginians, Romans, and Goths, was subdued by the Arabians, in the ninth century; in the eleventh, the Normans conquered it, and it remained united with Sicily, until it became in some measure independent, under the Knights of St John.

8. The *LYCIAN* is only known from a few short inscriptions, copied by Mr R. Cockerell, and published in Mr Walpole's collection, together with two or three longer ones, which have been lately brought from Antiphellos, by the enterprising and indefatigable

Mr W. J. Bankes. By means of a proper name, in **Languages.** one of Mr Cockerell's inscriptions, we obtain a part

of the alphabet; thus it is A, Δ, D; E, I; F, R; S,

s; and probably A, H; and I, L. A further comparison of the different parts of the other inscriptions, with the Greek phrases that almost uniformly accompany them, implying "FOR HIMSELF AND HIS WIFE AND HIS CHILDREN;" gives us the words A, or AT'HI, *himself*; SA, *his*, or for *his*, HRDI, or perhaps HROI, *wife*; TIDAIMI, *son*; TIDAIMA, *children*; and ATBI, *and*. It does not appear that any of these words would authorise us to place the Lycian language as a member of the great Indoeuropean class; but it is reported to have been much mixed with Greek, and on account of its geographical situation, it may be allowed to occupy a temporary rank between the principal Oriental and European languages. If it has a shadow of likeness to any other language, it is perhaps to the Cimbric; and *Tidaimi* may also possibly be allied to the Greek *Titheno*, to nurse.

9. Respecting the ancient *PHRYGIAN*, we have a few traditions only, which at least agree in giving it a high antiquity, as the source of several Greek words. Thus, Plato observes, in his *Craftylus*, that the terms denoting *fire* and *water* are not derived from any other Greek words, but are Phrygian primitives. It seems, however, that *water* was called *Bedü* by the Phrygians, and the word resembles the *Bada*, *Bath*, of the northern nations, as well as the *Vate*, *water*, of the Swedes; *Moirai*, the fates, derived from the Phrygian, is compared to *Meyar*, virgins, of the Gothic; and *Bek*, *bread*, is as much like our *Bake*, as like the Albanian *Buk*, *bread*.

10. The *Greek* has no very intimate or general connexion with any of the older languages, which have been preserved entire, although there are a number of particular instances of its resemblance to the Sanscrit, some of which have been already mentioned; it has also many German and Celtic words, some Slavonian, and, as it is said, a few Finnish. It can only have been immediately derived from the language of the neighbouring Thracians and Pelasgians, who seem to have come originally from the middle of Asia, through the countries north of the Black Sea, and to have occupied not only Greece and Thrace, but also the neighbouring parts of Asia Minor, where they probably retained their ancient dialect to a later period than elsewhere. The whole of the Thracian states were greatly deranged by the expedition of the Celts, in 278 B. C., which terminated in their settling the colony of Galatia. The Dacians, or Getae, who principally occupied Bulgaria, extended themselves further northwards, and afterwards constituted the Roman provinces of Moesia and Dacia, which were conquered by the Goths, in the third century. The Macedonians, in the time of Alexander, spoke a language which was nearly unintelligible to the Greeks in general; even the Pelasgi, in Epirus and Thessaly, long retained a dialect materially different from their neighbours; and in Arcadia still longer. The Hellenes, who emigrated from Asia Minor into Greece, were not sufficiently

languages, numerous to carry their own dialect with them, although the language assumed their name. The Graeci in Italy were Pelasgians, although Dionysius of Halicarnassus includes them in the denomination Hellenic; their language must have been Aeolodoric, and it was in this form that the Latin received its mixture of Greek; the Lacedemonian also retained it till a late period, writing, for instance, instead of *Pais*, *Poir*, as in *Latin Puer*. The *Aeolic* appears once to have extended over Attica, and to have left some Aeolisms in the old *Attic* dialect. This dialect was the principal basis of the *Common* language of Greece at a later period, which must have been the most cultivated under the protection of the court of Alexandria, and which continued to be spoken and written in the highest circles of Constantinople throughout the middle ages; by degrees it degenerated into the modern *Romæic*, having received a mixture of Turkish and Italian, and perhaps of some other neighbouring languages.

11. The GERMAN family is sufficiently connected with a variety of others, belonging to the Indo-European class, to be admitted into it upon a very short investigation. Its resemblances to the Greek, within the compass of the Lord's Prayer, besides *Father* and *Name*, are *Wille*, *Wollen*, Gr. *Boule*, perhaps *Brof* or *Proat*, *bread*, like *Artos*, and *Freyen* or *Lösen*, like *Rhüein* and *Lüsein*. Dr Jamieson has shown very clearly, in his *Hermes Scythicus*, how immediately the structure of the Gothic languages is derived from that of the Greeks. Thus the *MIN* of the Greek infinitive became in the Moesogothic *an* or *IAN*, in German *EN*; the *ICOS* of the adjectives, Moesogothic, *AGS*, *IGS*, or *EIGS*, as *mahteigs*, *mighty*; Germ. *machtig*; the Slavonians have *ski*, the Swedes *ska*: the *INOS*, Lat. *ENUS*, Anglosaxon *EN*: the *LICOS*, Latin, *LIS*, German *LICH*, English *LIKE*; thus *pelicos* is *what like*, as least in Scotland; the Moesogothic *swaleiks* is *our such*; *sameleiks* is *similis*. *LOS*, *LIS*, *LION*, of diminutives, in Latin *LUS*, becomes in Moesogothic *ILO*, as *barnilo*, a little child; in German *männl* is a little man. Among the pronouns we have *Egō* in Greek and Latin, Moesogothic *IK*, Icelandic *EG*, Swedish *JAG*; *EMOU*, *MOU*, Gr., Latin *MEI*, Moesogothic *MEINA*, German *MEINER*; *EMOI*, *MOI*; Latin *MIHI*, Moesogothic *MIS*; Swedish *MIG*, Dutch *MIJ*; *EME*, *ME*, Latin *ME*, Moesogothic *MIK*, Anglosaxon *ME*, Dutch *MY*. *SÜ*, Doric *TÜ*; Latin *TU*; Moesogothic *THU*. *IS* in Latin, Moesogothic *IS*; *EJUS*, Moesogothic *IS*, *IZOS*; *ID*, Moesogothic *ITA*, English *IT*; *QUIS*, *CUJUS*, *CUI*, *QUEM*; Moesogothic *QUHAS*, *QUHIS*, *QUHE*, *QUHANA*, the last having the *N*; as the Greek *HON*; *UTER*, *WHETHER*; *ALTER*, *OTHER*, seems to be derived from *ANTHER*, *ENTHERA*, meaning *one of them*, so that in this instance the Gothic has the appearance of the greater antiquity, while the Greek affords, on the other hand, an etymology for *ΕΚΚΙΝΟΣ*, from *ΕΚΕΙ*, there, which is wanting to the Moesogothic *GAINS* or *JAINS*, the Alemannic *GENER*, the German *JENER*, and the English *YONDER* or *YON*. Again, among the numerals, *DEKA* has been derived from *DEO*, as if both hands were tied together, and *PENTE* has a strong resemblance to *PANTA*, as if *all* the five fingers were reckoned: and on the other hand, *da cuig* in Gaelic,

meaning twice five, has been considered as the original of *DEKA*. But none of these etymologies seems to be so decisive of originality as that of *caterva*, which is evidently related to *turba* or *turma*; while the first syllable remains unexplained in Latin, but in the Celtic we have *cad tarf*, or *cath tarf*, a *war troop*, agreeing undeniably with the sense. For another example, we may take *ventus* and *wind*, for which we find no Latin etymology, while the German furnishes us with *wehen* to *blow*, and thence *wehend* and *wind*; the words *nodus* and *knot* afford also a similar instance, *nodus* having nothing nearer to it in Latin than *neo* to spin, *necto* to unite; but in German we have *knütten* to *join*, and in English *knit* and *knead* from the same root. The degrees of comparison are expressed in Greek by *EROS* and *ISTOS*; in Anglosaxon by *ER* or *ERA*, and *IST* or *AST*. *Er* seems to mean *before*, as well as the Latin *OR*. The Coptic has no comparative, but for *better than I*, the Egyptians said *very good before me*. It would seem at first sight natural to make *than* a preposition, as well as *before*, and to say *better than me*; but the fact is that in English, as well as in German, it was usual of old to say *then* or *denn* in this sense; and *he is wiser than I* meant only, *he is wiser BEFORE, THEN I follow*. The idea of time or place is now dropped as unessential to the kind of priority in question, but the ground of the grammatical construction remains unaltered. In Moesogothic the comparative termination is *IZO* or *OZO*; the superlative *ISTS* or *ISTA*; thus the Greek *MEIZON* becomes *MEIZO*: and *MAISTS* is obviously *MEGISTOS*. The old *megalos* is *mikils*, *mickle* or *muckle*; and *minor*, *minimus*, became *minnizo*, *minnists*; in Persian *mih* is *great*, *mihter*, *greater*, *mihtras*, *greatest*; *better* seems to be from the old German *bied* or *bieder*, *upright*, *honest*, and resembles the Persian *bihter*, *better*. The Moesogothic verbs have also some striking resemblances in their form to the Latin, thus the present tense of *to have* is *HABA*, *HABAIS*, *HABAITH*: *HABAM*, *HABAITH*, *HABAND*; *HABAIT* is *HABAIDA*. *HABENS*, *HABANDS*; *HABENTIS*, *HABANDIS*; *HABENTEM*, *HABANDAM*; *HABENTES*, *HABANDANS*. The substantive verb singular in Greek is *EIMI*, *EIS*, *ESTI*; the plural in Latin *SUMUS*, *ESTIS*, *SUNT*; the Moesogothic has *IM*, *IS*, *IST*, *SIJUM*, *SIJUTH*, *SIND*: and *SIS* is *SIJAIS*; *ESSE*, *WISAN*. The Moesogothic nouns frequently retain the resemblance of the Greek more strongly than their more modern derivatives; thus a *TOOTH* does not seem to point very immediately to *DENTEM* or *ODONTA* as its source; but the older form *TUNTHU* is clearly the intermediate stage of this modification; and numberless other instances of the same kind might easily be found.

The Germans were known, as early as the time of Pytheas, that is 320 B. C. as consisting of the Jutes in Denmark, the Teutones on the coast to the east of them, the Ostiaenes next, and lastly the Cosini, Cotini, or Goths. Professor Adelung imagines that the eastern nations, or Suevi, employed almost from the earliest times a high German dialect, and the western, or Cimbri, a low German; the Suevi he supposes to have been driven, at a remote period, into the south of Germany by the Slavonians; and some of the Goths appear to have extended as far as

Languages. the Crimea. The *Bible* of Ulphila, in the Gothic or Moesogothic of 360, is the oldest specimen in existence of the German language. Besides the Greek and Latin, which appear to prevail so much in the language, it exhibits a considerable mixture of Sclavonian and Finnish; the translation is far more literal than it could be made in any of the more modern dialects of the German; and sometimes appears to follow the text with somewhat too much servility.

The modern *German*, founded on the higher dialects of Saxony, was fixed and made general by Martin Luther. There are many shades of dialect and pronunciation in the different parts of this diversified country, but none of them of any particular interest, or established by any literary authority. There are still some German colonies, in the territories of Vicenza and Verona, called the *Sette Comuni*, which retain their language. The *German Jews* have a peculiar jargon, borrowed in some measure from their brethren in Poland, which they write in Hebrew characters; and another similar mixture of discordant dialects is spoken by the *Rothwelsh*, a vagabond people in the south of Germany, who have sometimes been confounded with the Gipsies.

The *Low Saxon*, or *Platt Deutsch*, is spoken about Halberstadt, and further north, in the countries between the Elbe and the Weser; it seems to be intimately connected with the Frieslandish and Danish, as well as with the English. The *Frieslanders* originally extended from the Rhine to the Ems, and the Cauchi, thence to the Elbe; these countries still retain a dialect materially varying from those of their neighbours. The *Brokmic* laws of the thirteenth century exhibit some remarkable differences from the German of the same date: thus we find in them *Redieva* a judge, or *Reeve*, instead of *Richter*; *Kenne, kin*; and *sida, side*, as in Swedish, instead of *seite*. The *Batavian Frieslandish* approaches very much to the English; it has several subdialects, as those of *Molkwer*, and *Hindelop*. Some of the *Cauchish Frieslanders* remain in the territory of Bremen; the North Frieslanders occupy Heligoland, Husum, and Amröm.

The *Dutch* language is a mixture of Frieslandish, Low Saxon, and German, with a little French. It appears, from *Kolyn's Chronicle*, to have been distinctly formed as early as 1156.

The Scandinavian branch of the Germanic family is characterized by the want both of gutturals and of aspirates, which renders its pronunciation softer and less harsh; and by some peculiarities of construction, for instance, by the place of the article, which follows its noun, both in *Danish* and *Swedish*, instead of preceding it, as in most other languages. The name of *Denmark* is first found in the ninth century; until the sixth, the people were called *Jutes*. *Norway*, in the ninth century, was termed *Nordmanland*. A corrupt *Norwegian* is still, or was lately, spoken in some of the *Orkneys*, which were long subject to Norway and Denmark. In the eastern parts of *Iceland*, the language is much like the *Norwegian*; but, on the coast, it is mixed with *Danish*. The oldest specimen of *Icelandic* is the *Jus Ecclesiasticum* of 1123. The term *Runic* relates to the rectilinear

Languages. characters cut in wood, which were sometimes used by the Scandinavian nations. The *Swedes* are derived from a mixture of Scandinavians with Goths from Upper Germany; but their language does not exhibit any dialectic differences corresponding to this difference of extraction. Mr Townsend has given us a list, from *Peringskiöld*, of 670 Swedish words, resembling the Greek; but it must be confessed that the resemblance is in many cases extremely slight.

The *Saxons* are mentioned by Ptolemy as a small nation in Holstein; whence, in conjunction with the Frieslanders, and the Angles of South Jutland, they came over to England, about the year 450. The Saxons settled principally south of the Thames, the Angles north. At the union of the Heptarchy, the Saxon dialect prevailed, and the English, which nearly resembled the Danish of that time, was less in use; but new swarms of Danes having inundated the north of England, in 787, the Danish dialect was introduced by Canute and his followers; and it is about this period that our earliest specimens of the Anglosaxon are dated. The Saxon dialect again obtained the ascendancy under Edward the Confessor; and although some French was introduced by this prince, and still more by William the Conqueror, into the higher circles of society, the courts of law, and the schools, yet the use of the French language never became general among the lower classes, and the Saxon recovered much of its currency in the thirteenth century, when the cities and corporate towns rose into importance, under Edward the First; in the fourteenth century, it was permanently established, with the modifications which it had received from the French; and it may be considered as truly English from this period, or even somewhat earlier, at least if Pope Adrian's rhymes are the genuine production of 1156. It is still much more German than French; in the Lord's Prayer, the only words of Latin origin are *Trespass*, *Temptation*, and *Deliver*. Professor Adelung's remarks, on the simplicity of the English language, appear to be so judicious as to deserve transcribing. "The language," he observes "only received its final cultivation at the time of the Reformation, and of the civil disturbances which followed that event; nor did it acquire its last polish till after the Revolution, when the authors who employed it elevated it to that high degree of excellence, of which, from its great copiousness, and the remarkable simplicity of its construction, it was peculiarly capable. It is the most simple of all the European languages; the terminations of its substantives being only changed in the genitive and in the plural, and the alterations of the roots of the verbs not exceeding six or seven. This simplicity depends in some measure on a philosophical accuracy, which is carried systematically through the whole language, so that the adjectives, participles, and article, are indeclinable, being in their nature destitute of any idea of gender, case, or number; and the form of generic distinction is [almost entirely] confined to objects which are naturally entitled to it. The pronunciation, on the other hand, is extremely intricate, and foreign proper names, in particular, are much mutilated, whenever they are adopted by the English."

12. The *Celtic* family forms a very extensive and

languages very interesting subdivision of the Indoeuropean class. It has been asserted, by some writers, "that the six original European languages, the Iberian, Celtic, Germanic, Thracian, Slavonian, and Finnish, were just as distinct as the beginning of their history as they now are;" but this assertion must be subjected to considerable modification; the thing is in itself so improbable, as to require far more evidence than we possess to establish it, even if that evidence were of a more decisive nature; and, in fact, it will actually be found, upon a comparison of the Gothic of Ulphila with the more modern dialects, that the Germanic of that day did approach more nearly, both to the Celtic and to the Thracian or Greek, than any of its more modern descendants do. The change of *TUNTHU* into *TOOTH*, for which the Germans have *ZAHN*, has already been noticed; the *ATTA* and *HIMINA* of Ulphila seem to be more like the Irish *at'air* and *Neambh*, than the modern *Vater* and *Himmel* are; and the Moesogothic *VAIR*, which answers to the Cimbric *FEAR*, a man, is not at present found in German, though its traces may still be observed in the *Firiobarno* of the Franks, in 1020; the antiquity of the root is shown by the Celtic names in *Cæsar* beginning so often with *VER*, and still more strongly by the testimony of Herodotus, that the Scythian called a man *AIOR*. At the same time, therefore, that we admit the propriety of considering the Celtic and Germanic as families clearly distinct, with respect to any period with which we are historically acquainted, we must not forget that they exhibit undeniable traces of having been more intimately connected with each other, and with their neighbours, in the earlier stages of their existence. The resemblances of the Celtic to the Latin are too numerous 'o require particular notice, the immediate and extensive connexion between these languages being universally admitted; but if any evidence were desired on this subject, it might be obtained in abundance, by a reference to Court de Gebelin's *Monde Primitif*. With respect to the Greek, the terms *Hael*, sun; *Dur*, water; *Deru*, oak; *Garan*, crane; *Cruun*, ice, are among the Celtic words of the most indisputable originality, and their resemblance to *Helios*, *Hüdor*, *Drüs*, *Geranos*, and *Cruwen*, is equally undeniable. We find, also, in the Cimbric, *Bas*, low, connected with *Bathüs*, *Bara*, bread, perhaps with *Bora*, food; *Deyrnas*, kingdom, with *Türannis*; *Dyro*, give, with *Doreue*; and *Gogorian*, glory, perhaps with *Gauriaon*, exulting. With the Gorman it is easy to find a number of very near approaches to identity, even in that Celtic, which can be proved, principally from the etymologies of proper names, to be prior to the date of any known or supposed secondary intercourse or mixture of the natives concerned; thus we have, either accurately or very nearly in the same signification, *Ap*, *Affe*, or *Ape*; *Barra*, *Barre*; *Bleun*, *Blume*; *Bolgan*, *Balge*; *Brig*, *Berg*; *Brogil*, *Brihl*; *Carra*, *Karre*; *Doga*, *Teich*; *Galb*, *Kalb*; *Garan*, *Kranich*; *Gnabat*, *Knabe*; *Lancea*, *Lanze*; *Marc*, *Mähre*; *Marga*, *Märgel*; *Redya*, *Reiten*; *Rit*, or *Rat*, *Rad*; and *Ur*, *Auer*; and it is impossible to suppose that so numerous a series of coincidences can have been derived from accidental causes only.

The Celts may be imagined to have emigrated

from Asia after the Iberians, or Cantabrians, and before the Thracians, or Pelasgians, settling principally in Gaul, and spreading partly into Italy, under the name of Ausonians and Umbrians. In 570 B. C., they undertook expeditions, for the purposes of conquest, but they were subdued by the Romans. Their language was current in Gaul till the sixth or seventh century, when it was superseded by the rustic Roman, which by degrees became French: in Ireland and Scotland, it has remained with few alterations; in Wales and Brittany, it has been more mixed. The Gauls must have peopled Britain at least as early as 500 B. C. The true ancient Britons are the Highlanders of Scotland only, having been driven northwards by the Cimbri; they still call their language Gaelic. The Irish are probably derived from these Highlanders; they were originally termed Scots or Scuits, that is, fugitives, from the circumstance of their expulsion from Britain; so that, where the Scots are mentioned before the tenth century, as by Porphyry, in the third, we are to understand the Irish. Gildas, in 564, sometimes calls them Scotch, and sometimes Irish. After the retreat of the Romans from Britain, a part of them re-entered Scotland, about the year 503, and changed its name from Caledonia to Scotia Minor. In 432, St Patrick laid the foundation of the civilisation of Ireland; and, in the seventh century, several Irish priests undertook missions to the continent. At the beginning of this century, some Scandinavian freebooters had begun to visit Ireland; and, in the year 835, they formed large colonies of emigrants, who established themselves firmly in that country, and in the Scottish Islands, bringing with them many Gothic words, which became afterwards mixed with the Celtic, and which seem to constitute about one fifth part of the modern Irish and Gaelic, 140 Gothic words being found under the first six letters of the alphabet only. Some of these Normen remained distinct from the Irish till the year 1102. The oldest specimens of the Irish language, admitted by the continental critics to be authentic, are of the ninth century; though some of our antiquaries have imagined they have discovered records of a much earlier date. The Gaelic of the Isle of Man is mixed with Norwegian, English, and Welsh. A Gaelic colony, formerly established at *Walden*, in Essex, has been placed by Chamberlayne in Italy, as a nation of *Waldenses*.

The Cimbric or Celtogermanic language was remarked by *Cæsar* as differing from the Gallic, although the distinction has not always been sufficiently observed. The Cimbrians seem to have existed as a nation 500 or 600 years B. C.; the Gauls called them Belgæ; they invaded Britain a little before *Cæsar*'s time, and drove the ancient inhabitants into the Highlands and into Ireland. Having called the Saxons to their assistance against the Scots and Picts in the fifth century, they were driven by their new allies into Wales, Cornwall, and Brittany. Their language is remarkable for the frequent changes of the initial letters of its radical words, in the formation of cases and numbers; thus from *Den*, a man, in *Britannish*, is derived the plural *Tud*; from *Vreg*, a woman, *Groages*. Almost half of the

Languages.

Welsh language seems to be German, and half of the remainder is perhaps Latin or Celtic; of the Britannic about half resembles the Latin or French. Britanny was originally inhabited by the Armoricans; whether they were properly Belgæ or Gauls is uncertain; the country was named Britannia Minor from the emigration of the British in 449; these new comers mixed with the original inhabitants, all speaking the same language, and in a few years became so numerous, as to be able to send an army of 12,000 men to the assistance of the Emperor Anthemius.

Professor Adelung is disposed to consider the German portion of the different branches of the Celtic, which varies from one fifth to one half of the whole language, as an accidental mixture, and derived through different channels. But we cannot in all cases find any historical evidence of the existence of these channels; it is difficult, for example, to suppose that the Scandinavian incursions were able at any early period to influence the language of the Highlands of Scotland; and wherever it happens, as it frequently does, that no term is to be found, in the Irish, the Gaelic, or the Welsh, for expressing the same idea, besides the word that they all have in common with the German, it is scarcely possible to believe that there ever was any other Celtic word, which has been so uniformly superseded by independent causes. We find, for instance, under the two first letters of the alphabet only, the words *Ap*, or *Apa* in Irish, *Ap* in Welsh, *Affe* or *Ape* in Gothic; again *Abal*, *Afal*, *Apsel*; *Angar*, *Aneang*, *Enge*; *Bacuil*, *Bach*, *Backen*; *Barrad*, *Barr*, *Bare*; *Beoir*, *Bir*, *Bier*; *Buail*, *Buall*, *Beil*; *Bocan*, *Bwch*, *Bock*, *Brathair*, *Brawd*, *Bruder*; *Bul*, *Bula*, *Bulle*; and the same agreement is found in almost all other instances of German words that are detected in the Irish language.

The much disputed question, respecting the antiquity of the poems attributed to Ossian, has an immediate reference to the history of the Celtic languages. It has been observed with apparent justice, by Professor Adelung, who is not in general sceptical on such occasions, that if these poems were really very ancient, their language could not but exhibit marks of antiquity; there is an Irish *Leavre Lecan*, at Paris, written in the thirteenth century, and scarcely intelligible to the best Irish scholars of the present day; the oldest Gaelic manuscripts have also peculiar expressions no longer in use; while the works, supposed to be the productions of a period so much more remote, are found to be in "excellent modern Gaelic, impressed with all the marks of the language of Christianity, and of that of the Norwegian invaders, whether these conquerors may be supposed to have influenced the Gaelic language immediately in Scotland, or by the intervention of Ireland." It must not, however, be forgotten that these marks of Scandinavian intercourse are somewhat more ambiguous than Professor Adelung is disposed to admit; and that a book written in the thirteenth century is more likely to have preserved the language in an antiquated form, than poems so marvellously committed to memory from continual recitation only, by people supposed to understand

them, and of course imperceptibly modifying the expressions without intending to alter them. But since an invasion from Lœchlin, that is, Denmark or Norway, is actually mentioned in "Fingal," the author of the poem could certainly not have been older than the seventh or eighth century, if we are to credit the historical accounts of these invasions; and since in the poems discovered by Dr Matthew Young, St Patrick is introduced discoursing with Ossian respecting the Christian religion, we have an additional argument for denying that he was contemporary with Caracalla or Carausius; these Emperors having both lived in the third century, and St Patrick in the fifth.

14. The ETRUSCAN is only known as the immediate parent of the Latin, but it was written in a character totally different, and was read from right to left. Notwithstanding the industry and ingenuity of Lanzi, the evidence of the accuracy of his interpretations is somewhat imperfect. We should naturally have expected to find more words of a Celtic or Gothic origin, and not merely Greek or Latin words, with the terminations a little varied, as *Ustite* for *Ustura*, *Tribo* for *Tribus*, and *Urtic* or *Urtia* for *Heorte*; still less should we have expected that the same sense should be expressed sometimes by a Greek, and sometimes by a Latin word, as *Urtu* and *Puni* for Bread, *Capros* and *Feres* for a Boar. The Etrurians and Umbrians were originally a branch of the Celts, from Rhætia, as is shown by the similarity of the names of places in those countries, as well as by the remains of Etruscan art found in that part of the Tyrol; they are supposed to have entered Italy through Trent, about the year 1000 B. C., and to have afterwards improved their taste and workmanship under the auspices of Demaratus of Corinth, who settled in Etruria about 660 B. C.

15. The LATIN language is placed at the head of a family, rather with regard to the number of its descendants, than to the independence of its origin, being too evidently derived from the Celtic, mixed with Greek, to require particular comparison. The first inhabitants of Italy appear to have been Illyrians or Thracians, Cantabrians, Celts, Pelasgians, and Etrurians. Rome, from its situation, would naturally acquire much of the languages of these various nations, and at the same time much of the Greek from the colonies in the south of Italy. In the time of Cicero, the Italian songs, supposed to be about 500 years old, were no longer intelligible, even to those who sang them. We find, in an inscription still more ancient, and approaching to the time of Romulus, *Lases* for *Lares*; and for *Flores*, *Pleores*, which is somewhat nearer to the Celtic *Bleun*; in the time of Numa, for *Hominem liberum*, we have *Hemonem læbesom*; we find, also, a *u* added to the oblique cases, as *Capited* for *Capite*, which, as well as the termination *ai*, in the genitive *aulai*, *pennai*, is taken immediately from the Celtic, and is even found in modern Gaelic.

The Latin remained in perfection but a few centuries; in the middle ages, a number of barbarous words were added to it, principally of Celtic origin, which are found in the glossaries of Dufresne and Charpentier. At the end of the seventh century, it

Languages.

Languages. began to acquire the character of *Italian*, as *Campo divisum est*; and, in the eighth century, in Spain, we find, as an example of its incipient conversion into Spanish, *Vendant sine pechu, de nostras terras*. The formation of the Italian language may be said to have been completed by Dante, in the beginning of the fourteenth century; and it was still further polished by the classical authors who immediately succeeded him. It contains many German words, derived from the different nations who occupied in succession the northern parts of Italy, and some Arabic, Norman, and Spanish, left by occasional visitors in the south. It is spoken by the common people in very different degrees of purity. Among the northern dialects, that of *Friuli* is mixed with French, and with some Sclavonian. The *Sicilians*, having been conquered in succession by the Greeks, Carthaginians, Romans, Byzantines, Arabs, Normans, Germans, French, and Spaniards, have retained something of the language of each. *Sardinia* has given shelter to Iberians, Libyans, Tyrrhenes, Greeks, Carthaginians, Romans, Vandals, Byzantines, Goths, Lombards, Franks, Arabs, Pisans, and Arragonians; and the proper Sardinian language is a mixture of Latin with Greek, French, German, and Castilian. *Corsica* has also been occupied by a similar diversity of nations; its peculiar idiom is little known; but the dialect of the upper classes is said to approach nearly to the Tuscan.

Spain, after its complete subjugation by the Romans, enjoyed some centuries of tranquillity. The Vandals and Alans retained their power in Spain but for a short time; the Suevi, on the north coast, somewhat longer; and, from these nations, the rustic Roman, which had become general in Spain, received some words of German origin; it derived, however, much more from the Arabic, during the domination of the Moors, which lasted from the beginning of the eighth century to the end of the fifteenth; and, at one time, the Arabic was almost universally employed throughout the country, except in the churches. The Spanish language advanced the most rapidly toward perfection during the height of the national prosperity, which immediately followed the conquest of America; it was afterwards neglected, and again more particularly cultivated by the Academy of Madrid, in the eighteenth century; as far, at least, as an Academy can be supposed to have any influence in the modifications of a language.

The Portuguese is supposed to have received a mixture of French from the followers of Count Henry of Burgundy, under whom Portugal first formed a separate state, in 1109; but the language is very different from that of the confines of France and Spain; and the nasal vowels, which are remarkable in the Portuguese, differ materially from those of the French, or of any other nation. Many Latin words are retained in the Portuguese, which are not found in any other modern language; and it is remarkable that almost all the words of the language are contracted, by the omission of some of the radical letters of the originals.

The Rhetians, in the country of the Grisons, were subdued by the Romans in the time of Augustus.

Languages. They became part of the Alemannish kingdom, under Theodobert, in 539; their union with Switzerland took place in the beginning of the fourteenth century. Half of the Grisons speak the Romanish language, immediately derived from the Latin, though mixed with some German, which has been particularly made known by Mr. Planta's account of it, in the *Philosophical Transactions*. One third speak German, with some mixture of Romanish words, and the rest a bad Italian.

France, in the time of the Romans, was occupied by the Gauls, together with the Aquitani, who were probably Cantabrians, and the Cimbrians or Belgians. From the rustic Roman, mixed with the languages of these nations, the Romance was gradually formed. In the fifth century, the Franks took possession of the north-eastern part of the country; they retained their language for some centuries, but by degrees it became mixed with the Romance, and formed French, of which at least one fifth is supposed to be of German origin; though many of the German words seem to have been admitted through the medium of the Italian. In the south of France, the language remained more exempt from the influence of the German, under the name of the *Provençal*; and the troubadours contributed, especially from the eleventh to the thirteenth century, to give it refinement and currency; but, in later times, the *Langue d'oui* has prevailed over the *Langue d'oc*, which is now spoken by a few of the lowest class only.

The last and least genuine of the descendants of the Latin is the *Wallachian*, about one half of which is borrowed from the German, Sclavonian, and Turkish. The original Thracians of the country must have been in a great measure superseded by the successive settlements of various nations; in the third century, some of the Goths and Vandals; in the fourth, the Jazyges, after Attila's death; in the fifth, some Huns and Alans; about the end of the seventh, the Bulgarians, and afterwards the Petschenegs and Hungarians established themselves in it; and, in the thirteenth century, Wallachia became an independent state. The Latin part of this language has much of the Italian form, and had even assumed it as early as the fifth century. It must have been derived from Roman colonies, and more lately, perhaps, from the missionaries sent into the country by Pope Gregory XI. The *Dacian* or Hungarian dialect prevails on the north of the Danube; the *Thracian*, or *Cutzowallachian*, on the south; the latter is more mixed with Greek and Albanian. There is also a small Wallachian colony in Transylvania.

The *Cantabrian* or *Biscayan* has many words in common with the Latin, whether originally or by adoption, and was probably in some measure connected with the Celtic dialects, which were the immediate predecessors of the Latin, though still sufficiently distinct from them. The Cantabrian *Atta*, Father, has some resemblance to the Irish *A'air*, and the Moesogothic *Atta*; *Seru* is not wholly unlike *Coelum*; *Ereenjaa*, *Regnum*; and *Borondatia*, *Volutas*; the coincidence of *Gun*, Day, with the Tartarian, is perhaps more accidental. But the word *Lurre*, Earth, which seems at first sight so unlike any

other language, is in all probability the derivative of *Tellure*; and this form of the word affords, also, a connecting link with the Irish *Talu*, and may have been contracted into the more common Latin word *Terra*; a supposition which seems to lessen the probability of the original connection of this form of the word with the Greek *Era*, and the Sanscrit *Stira*. The Biscayan is still spoken in the angles of France and Spain, adjoining to the northern extremity of the Pyrenees. The same people were called Cantabrians in the north, and Iberians in the south, and extended between the Pyrenees and the Rhine, as Ligurians, or inhabitants of the coast. They have adopted a few German words, perhaps from the empire of the west Goths; and they have furnished the modern Spanish with more than a hundred original words of their own. The construction of the language is extremely intricate; its verbs have eleven moods, among which are a consuetudinary, a voluntary, a compulsory, and a penitinary. Larramendi's *Grammar*, published at Salamanca in 1729, is called *El Impossible Vencido*. A valuable abstract of the most interesting particulars relating to the language is found in the *Additions to the Milhridades*, by the Baron William von Humboldt, late Prussian Ambassador to the Court of Great Britain, printed at Berlin, 1816. Dr Young has lately remarked, in the *Philosophical Transactions* for 1819, that at least six of the words contained in Humboldt's vocabulary coincide very accurately with the Coptic, or ancient Egyptian, though they are not found in any of the languages of the neighbouring countries; and he infers that the chances are "more than a thousand to one, that, at some very remote period, an Egyptian colony established itself in Spain." It may be observed, that one of these words, *guchi*, little, appears to be also Turkish or Tartarian; so that it becomes a second instance of a coincidence between this language and the Cantabrian.

16. The connexion of the Sclavonian and Lithuanian, and of the other branches constituting the SLAVIC family, with the languages of the Indoeuropean class in general, is sufficiently established, without exceeding the limits of the Lord's Prayer, by the resemblance of *Nebi* or *Nebesi* to the Cimbric *Nefoedd*, and the Greek *Nephos*, and of *Wolja* and *Chljeb* to the Gothic *Wilja* and *Hlaif*. The *Sclavonians* are the descendants of the ancient Sarmatians, who were situated north of the Black Sea and of the Danube. They were conquered by the Goths, and then driven by the Tartars and Huns into the north-east of Germany, and the neighbouring countries. Procopius calls them *Spori*, and divides them into the *Sclavi* and the *Antes*, the latter, perhaps, the same as the *Wends*. They formed, at an early period, two principal states, Great Russia, about Novogorod, and Little Russia, on the Dnieper, its capital being Kiew. The Russians were a Scandinavian branch, under Rurik, to whom the Sclavonians of the former state submitted in 862, whence they were called Russians; and Rurik's successor, Oleg, conquered Kiew. After several vicissitudes, the Russians were liberated by Iwan Wasiliewitch, at the end of the fifteenth century; and this period was the

beginning of their greatness. Their language has some mixture of Greek, Finnish, Swedish, Tartarian, and Mongol. The ecclesiastical dialect was uniformly retained in all literary works, in the former part of the last century, but now the language of conversation is generally adopted in writing. This language is more immediately derived from that of Great Russia; that of the church, which is called the Slawenish, rather from Little Russia, and especially from the dialect of Servia. The *Malorussian* dialect is somewhat mixed with the Polish, and is spoken in Ukrain and Little Russia; the *Susdalian* is mixed with Greek and other languages, and is spoken in Thrace.

In 640, the Sclavonians took possession of Illyria, which before that time had been overrun by a variety of other nations, and they still retain it, under the names of Servians, Croatians, and Southern Wends. The *Servians* are supposed to have come from Great Servia, now East Gallicia, on the Upper Vistula; the *Croatians* from Great Chrobatia, probably situated on the Carpathian mountains. Cyril first adapted the Greek alphabet to the Sclavonian language in Pannonia; his letters were afterwards a little altered, and attributed to St Jerom, in order to reconcile the people to their use, and in this form they are termed Glagolitic characters. The Servian dialect is intermediate between the Russian and the Croatian. The Bulgarians speak a corrupt Sclavonian, which Boscovich, from *Ragusa*, could scarcely understand. The *Uskoks* are a wild race of the Bulgarians extending into Carniolia, and speaking a mixed language. The dialect of Slavonia and Dalmatia is nearly the same as that of Servia and Bosnia; the churches use the ecclesiastical language of Russia. In *Ragusa*, the orthography approaches, in some measure, to the Italian. The Servian is also imperfectly spoken by a small colony in Transylvania. The southern *Wends* were first distinguished in 630, and were probably so named, like the Veneti, from being settled on the shores of the Adriatic, the word *Wend* or *Wand* meaning Sea. They are now mixed with Germans in Carniolia, Carinthia, and Lower Stiria. In Hungary, there is a small colony, who call themselves *Slowens*, and speak the *Wendish* dialect of the *Sclavonian*. The western Sclavonians, or the proper *Sclavi*, write their language in the Roman characters; but the specimens, copied from Adelung, are accommodated in their orthography to the German mode of pronunciation.

The *Polcs* probably came with the Russians from the Danube into the countries abandoned by the Goths; the name *Pole* implies an inhabitant of plains. Their language was partly superseded by the Latin in the tenth century, when they received the rites of the Latin church; but it has in later times been more cultivated. The *Cassubians*, or *Kashubians*, in Pomerania, speak a Polish mixed with a little German. In *Silesia*, the names of places in the plains are Sclavonian; in the hills, more lately occupied, German; but German has been the language of Breslau ever since the year 1300.

The *Bohemians* emigrated, with the Moravians and Slovaks, into their present habitations, about the middle of the sixth century, after the destruc-

Languages. tion of the kingdom of Thuringia by the Franks and Saxons. There is a Bohemian hymn of the date 990, and a chronicle in rhyme, of 1310. One third of the Bohemians are of German origin, and speak a corrupt German.

The *Serbs*, or *Wends*, came about the same time into the countries between the Saal and the Oder, from the neighbourhood of the Volga or the Crimea; a few of them are still left in *Lusatia*, under the name of *Wends* or *Slavonians*, and some in *Misnia*. In *Pomerania* the *Wendish* became extinct about 1400; but the *Polabes* in *Lüneburg*, on the *Leyne*, kept up till lately a language consisting of a mixture of *Wendish* and *German*. The *Sorabie* of the Russian vocabulary seems to be the same with this *Serbian*.

Of the *Lithuanian* or *Lettish* language, two thirds are *Slavonian*, the rest is principally *German*. When the *Goths* had removed from the Baltic towards the Black Sea, their neighbours the *Aestii* remained for some hundred years independent, till in the sixth century the *Slavonians* incorporated themselves with them, and formed the *Lettish* people and language. The *Old Prussian* was spoken, at the time of the Reformation, in *Samland* and its neighbourhood, but it is now lost; it contained more *German* than the other *Lithuanian* dialects. The *Prussian Lithuanian* is spoken from the *Inster* to *Memel*, especially in *Insterburg*. The *Polish Lithuanian*, in *Samogitia*, has a little mixture of *Polish*. The proper *Lettish* is current in *Lettland* and *Courland*, it is purest about *Mittau* and *Riga*; the old *Courlanders* having been *Fins*, this dialect has received a little *Finnish* from them. The *Criwingian* is another dialect, spoken by the *Krewins* in *Courland*.

17. The *Tshudish* or *Finnish*, the *Hungarian*, and the *Albanian* languages, have some traits of resemblance to each other; they are placed as forming the *Sporadic* or scattered order of the great *Tatric* or *Asiatic* class, being in some measure geographically detached from the rest, and scattered through different parts of Europe: they immediately follow the *Indoeuropean* class, as exhibiting an occasional resemblance to some of the languages contained in it, though not enough to make it certain that the connexion is essential or original; thus the *Finnish* is said to have some coincidences with the *Greek*, the *Laplandish* with the *Hebrew*, the *Hungarian* with the *Finnish*, and the *Albanian* with all its neighbours.

The term *Tshudish* is employed as comprehending the *Fins*, *Laplanders*, *Esthonians*, and *Livonians*; a race of people of unknown origin; but in all probability unconnected with the *Huns* or *Mongols*. Their languages are remarkable for the great complexity of their structure; their nouns, for example, having from ten to fifteen cases, among which are reckoned, in the *Finnish*, a nuncupative, a conditional accusative, a factitive, a mediative, a descriptive, a penetrative, a locative, a privative, and a negative. The *Esthonian* has less direct variety of termination, but several intricate combinations. There is also a great multiplicity of dialects, partly from a mixture of *Scandinavian*, and partly from other causes; in

Languages. *Lapland* almost every church has a peculiar version of the service kept for its use. The *Finnish* is intermediate between the *Laplandish* and the *Esthonian*. The *Esthonians* are the *Aestii* of the Romans, the name implying *Easterly*, and being appropriate to the country, and not to the people. The principal dialects of their language are those of *Reval* and of *Dorpat*; some authors also consider the dialect of the *Krewins* in *Courland* as belonging to it. The *Livonian* is much mixed with other languages, and has been almost superseded by the *Lettish*. Among the *Laplandish* words, which *Rudbeck* has derived from the *Hebrew*, we find *Aedhame*, *Earth*, like the *Hebrew Adamah*; *Hadas*, *New*, *H. Khadesh*; *Hadshe*, the *Moon*, *H. Hhadesh*; *Jed*, the *Hand*, *H. Id*; *Isr*, *Man*, *H. Ish*; *Pothi*, persuaded, *H. Pathekh*; *Saedke*, law, *H. Tzedek*; and *Safothi*, rested, *H. Sabbath*. In the *Finnish*, *Kana* is something like the *English* and *German Hlen*.

18. The *Hungarians* inhabited in the fourth century the country of the *Baslikirs*, between the *Tobol*, the *Volga*, and the *Jauk*, perhaps as colonists, since their name signifies strangers; their language was spoken in this neighbourhood as late as the thirteenth century; in the sixth they were conquered by some of their *Turkish* neighbours; in the end of the ninth they were forced by the *Petschenegers*, a *Tartarian* nation, to remove nearer to the *Carpathian* mountains. They were then engaged in the *German* wars, and their country having been occupied during their absence by the *Bulgarians*, they took possession of the *Bulgarian* kingdom on the *Theiss*, as well as of *Pannonia*. Their language is somewhat like the *Finnish*, but the people are very different from the *Fins* in appearance; which might indeed be the effect of a difference of climate; but in fact the language appears to be still more like the *Slavonian*, with a mixture of a multitude of others; it has some words from various *Tartarian* dialects, *German*, *French*, *Latin*, *Armenian*, *Hebrew*, *Persian*, and *Arabic*; but it has no traces of the *Mongol*, nor is it possible that the people can be descendants of the *Huns*, whose character and cast of features can never be eradicated. The word *Coach*, so general in Europe, is originally *Hungarian*, having been derived from the town of *Kots*, where coaches are said to have been invented. The *Szecklers*, in *Transylvania*, speak a language like the *Hungarian*; it is uncertain whether they are a *Hungarian* colony, or remains of the *Petschenegers*; but, however this may be, there is little doubt that the *Hungarians* are principally of *Tartarian* extraction, though much mixed with other nations.

19. The *Albanians* speak a language, of which a considerable portion is *Greek*, *Latin*, *German*, *Slavonian*, or *Turkish*; but the rest seems to be perfectly distinct from any other language with which we are acquainted. They are probably connected with the *Albanians* between *Mount Caucasus* and the river *Cyrus*, who are supposed to be derived from the *Alani*; some of them seem to have entered *Bulgaria* as late as 1308. In 1461, many of them fled from the *Turks* to *Italy* and *Sicily*, where they still exist near *Reggio* and *Messina*. The *Clemen-*

languages. times are an Albanian colony, who followed the Austrian army in 1737; such of them as escaped from the pursuit of the Turks established themselves in Syrmia.

20. The languages referred to the *Caucasian* order have little to distinguish them from the rest of the class, except their geographical situation, in the immediate neighbourhood of the Caucasian mountains. They have a general resemblance to some others of the languages of Northern Asia, and particularly to the Samojedic dialects, spoken on the mountains between Siberia and the Mongols. Except the Armenian and Georgian, they are scarcely ever employed in writing; and principally, perhaps, from this cause, they exhibit as great a diversity in the space of a few square miles, as those of many other nations do in as many thousands. It is only conjectured that most of the inhabitants of these countries are derived from the miscellaneous fragments of expeditions of various nations, left behind in their passage through them at different periods.

The connexion of the *Armenian* with the Sanscrit and the Persian is just enough to make it equally possible, that the coincidences may have been derived from a common parent, or that one language may have simply borrowed detached words from the other. We find, in different parts of Mr Townsend's work, about ten Armenian words resembling some other language; these are, *Air*, a man, *Air*, Irish; *Atamn*, a tooth, *Odonta*, Greek; *Chuerk*, four, *Chatur*, Sanscrit; *Dor*, a Door; *E*, is, *Est*, Latin; *Es*, I, *Iaze*, Russian; *Gas*, a Goose, *Gans*, German; *Houze*, a House; *Lakeil*, to lick, *Leichein*, Greek; and *Sirt*, the Heart. Nothing is known of the history of the Armenian before the time of Miesrob, who translated the *Bible* into it, in 405; the historian Moses, of Chorene, was his pupil. The language flourished till the year 800, and is still preserved in tolerable purity, in the cloisters. The comic people speak a dialect more corrupt and mixed. The Fathers of the Armenian convent at Venice have been very laudably employed in the improvement of the literature of their nation, by the publication of several very elegant editions of Armenian books, which have been executed at their press; in particular, of an Armenian translation of Eusebius, containing some passages which are not extant in Greek, and said to have been copied from a manuscript of great antiquity at Constantinople; it is, however, very remarkable, that, as they candidly confess, the copy, when first received by them, contained the corrections and additions of Scaliger, in conformity with the text of the printed Greek edition, and the copyist, when questioned, asserted that he had merely translated and inserted passages of his own accord, and in silence, in order to make the work more perfect. Still the Armenian Eusebius is a very handsome book, and every way calculated to do credit to the Venetian editors and their patrons; a Latin translation of it only has been published by Angelo Mai at Milan.

21. The Georgians are supposed to have derived their name from the river Cyrus or Gur, and to have extended formerly to Colchis, under the denomination of Iberians. Moses of Chorene, in the fifth century,

mentions the Georgian translation of the *Bible*. The old language is still preserved in the churches, and the common dialect of the country is derived from it, together with the *Kartuelish*, *Imirettish*, *Mingrelish*, and *Suanelish*, which are varieties of that dialect; the *Tushetish* is mixed with some Kistic. The Georgians have no fewer than thirty seven letters, and among them a variety of aspirates and sibilants, of no very agreeable sounds.

22. The ABASSIC nations seem to be the oldest inhabitants of the Caucasian country; (23.) the CIRCASSIANS are situated to the east of them, on the promontory of North Caucasus; (24.) the OSSETES, on the left of the Terek, north of the mountain; the dialect of the *Dugors* is scarcely distinguishable from this: (25.) the KISTIC, spoken by the *Ingushans*, and their neighbours, at the head of the Terek, is connected with the Tushetic Georgian. 26. The LESGIANS, east of Caucasus, on the Caspian Sea, have a number of distinct dialects, or rather languages; thus, the *Chunsag*, and *Avaric*, the *Dido*, the *Kasi Kumuk*, the *Andi*, and the *Akushan*, have little connexion with each other, except that the *Dido* somewhat resembles the *Chunsag*, of which the *Avaric*, the *Antsug*, and the *Dzhar*, seem to be subordinate dialects. The *Kasi Kumuk* appears to have adopted some words of the Armenians, and the *Andi* and *Akushan* of the Georgian. The dialect of *Kubesha* resembles that of *Akusha*, and retains no traces of a supposed European origin.

27. The languages of the central and elevated parts of Asia are comprehended in the order *Tartarian*; they extend from the Caspian Sea to the mouth of the Amur, through countries which have been, in former ages, the constant scenes of emigration and barbarism. The *Turcotartarians* are supposed to correspond to the descendants of the Magog of the Scriptures, and to some of the Scythians of the Greeks. The Turks of Turkestan seem to have been the Massagetæ and Chorasmii of the ancients; their country extended North of Persia and Tibet, from the Caspian to the Altaic mountains. In the twelfth century, they were brilliant and victorious; at present, a few of their descendants only are left in the neighbourhood of the Mongols, and their language is no longer spoken; the Turcomans, scattered in Persia and Arabia, are derived from the same race. The Osmans, now commonly called Turks, left Turkestan in 545, and succeeded in the conquest of Persia. They were denominated Osmans, from one of their leaders, in the fourteenth century; their language has been much mixed with Arabic and Persian. This language, with the neighbouring dialects, has been considered in the table as belonging to a family called *Caspian*, the word *Tartarian* having been previously applied to the whole order; several of these dialects exhibit a mixture of words from the language of the Mongols, which, as well as the Calmuk, has a sufficient connexion with them to be arranged as belonging to the same Turcotartarian family: it would, perhaps, be equally correct to consider some of them rather as distinct languages than as dialects of a single one; but it is not easy to discriminate those which are entitled to this rank; and, on the other hand, some specimens have been admitted, from the Comparative Voca-

languages. bularies, which scarcely deserved to be noticed as separate dialects. The *Bucharians* are situated between the Oxus and Jaxartes, on the river Koly; they still retain some traces of a superior degree of civilization, by which they were once distinguished; their language is little known, but it seems to be at least as much connected with the Median and Arabian families as with the Caspian. The Tartars were described by the terms Scythians, Bulgarians, Avari, and other appellations, before they were conquered and united by Genghizkhan the Mongol; in the year 1552, they became subject to the Russians. The most westerly are, the *Nogaic* or *Nagaic*, and Crimean Tartars; their language is much like the Turkish, but mixed with some Mongol. Those of Cumania in Hungary have now forgotten their original language, and speak the Hungarian; the last person who understood the Cumanian having died in 1770; they entered Hungary in 1086, and became Christians in 1410. The Tartarian, or rather Caspian, is spoken in great purity about *Kasau*; a dialect somewhat different in Orenburg; and another by the *Kirghishes*, who occupy part of the ancient Turkestan. "Among the Siberian Tartars, the remains of the kingdom of Turan, some are Mahometans; others, as the Turalinzie villagers, have been made Christians; at least, the Archbishop Philophei performed the ceremony of baptizing them, by ordering his dragoons to drive them in a body into the river." The inhabitants of the banks of the *Tara*, a branch of the Irtysh, are said to be derived from the Bucharians. The *Tshulimic* Tartars enjoy the same advantage as the Turalinzie, and are considered as Christians by the Russians. The *Teleutes*, in Sonjor, are heathens, nearly like the Shamanites of India. The *Jakuts* extend along the Lena to the sea; their language contains some Mantshuric and some Tungusic; that of the *Tshuwashes*, on the Volga, is said to have been once completely distinct from the Tartarian or Caspian, and even at present, though more mixed with it, may require to be classed as forming a separate species.

The *Mongols* are marked by their features as a race very different from the other Tartars; the character of their countenance seems to be easily propagated from father to son, and never to be completely effaced; their original habitation appears to have been in the neighbourhood of the Altaic mountains. The description of the Huns, found in Ammian, Procopius, and others, agrees exactly with the present Mongols, whom the Chinese still call *Kiong nu*; and more particularly with the Calmucks: the proper names of the Huns are also found to be explicable from the Mongol language. In the first century they were driven westwards by the Chinese: under Attila they penetrated into the middle of Europe; and they were little less successful at subsequent periods, under Genghizkhan and Timur Leng. When they were expelled from China, after having held it in subjection for more than a century, they carried back no civilization with them; nor was either of the languages permanently affected by this temporary mixture of the nations, although the physiognomy of the Chinese bears ample testimony of its having once existed. The construction of their

language seems to be very indirect and figurative. Languages. Mr Townsend has copied from General Vallancy a long list of words, in Strahlenberg's *Mongol Vocabulary*, which agree very remarkably with the Irish; among these we find *Are* and *Ere*, man, Irish *Ar*, *Air*, *Fear*; *Arul*, a spindle, Irish *Oirle*; *Alemamodo*, an apple tree, Irish *Anhaltmhaide*; *Asoc*, to ask, Irish *Ascadh*; *Bairhu*, I live long, Irish *Buoth*, long life; *Bugu*, a buck, Irish *Boc*, a he goat; *Choy* a ewe, Irish *Choi*; and *Choraga* a lamb, Irish *Cuorog*, without going any further in the alphabet. The last two instances are very striking, and seem to point very strongly at the part of the east from which the Celts may be supposed to have originally emigrated. The *Calmuck* dialect is somewhat mixed with the neighbouring Tartarian. The Tagurians, or Daurians, between the lake Baikal and the Mongol hills, are said to be of Mantshuric origin; but their language evidently resembles the Calmuck. The *Burattish* is from the Russian Vocabularies.

28. The *Mantshurians* are sometimes improperly called Eastern Mongols; they are subjects of the empire of China. Their language is rude, and not much like the Chinese, though evidently derived from the monosyllabic class; it has some few words in common with the European languages, as *Kiru*, patient; *Kirre*, German, *Cicur*, Latin, tame; *Furu*, *Furor*; *Lapla*, rags, *Lappen*, German; *Sengui*, blood, *Sanguis*; *Ania*, a year, *Annus*; but considering the remoteness of their situation, we can scarcely form any conclusion from the occurrence of these resemblances. Mr Rémusat has lately been appointed Professor of this language at Paris; but it will probably be difficult for him to render its study very popular in the midst of so busy a metropolis. Whether the language of the island of *Sagalien*, opposite to the mouth of the Amur, is a dialect of the Mantshuric, or totally distinct, and requiring to be classed with the insular languages, appears to be not yet sufficiently ascertained. The *Corean* has been supposed to be a mixture of Mantshuric and Chinese. the Coreans do not understand either of those languages when they are spoken; but this fact is perfectly compatible with the supposition.

29. The *Tungusians*, in the east of Siberia, subject to the Chinese, speak a peculiar language, mixed with some Mongol; the Russian Vocabularies contain specimens of a variety of their dialects, besides those of the Tshapogirs on the *Jenisei*, and the Lamuti on the sea of Ochotsk, none of them particularly interesting or remarkable.

30. The languages belonging to the *Siberian* order occupy the principal part of the north of Asia between the mountainous Tartarian territory and the Frozen Sea. At the commencement of this order, we find a variety of inconsiderable nations in the neighbourhood of the confines of Europe and Asia, which have their distinct languages, probably formed in times comparatively modern, out of the fragments of others. They have almost all of them some Finnish words, but none a sufficient number to justify us in considering them as dialects of the Finnish language, although the people were very probably connected with the Fins, as neighbours, in the middle ages, on the banks of the Dwina and

languages elsewhere. The *Sirjanes*, in the government of Archangel, speak nearly the same language with the *Permians*, who are partly in the same government, and partly in that of Kasan. The *Wotiaks*, on the Wiatka, also in Kasan, have a dialect which seems to be intermediate between the Permian and the Tshere-*missic*. 31. The *Woguls*, situated on the Kama and the Irtysh, afford specimens of several dialects in the Russian collection; they seem to have borrowed a few words from the Hungarian, and much more from the language of the *Ostiaks* (32), who are also divided into several races. 33. The *Tsheremisses*, situated on the Volga, in Kasan, have a little mixture of Turcotartarian. 34. The *Morduins*, on the Oka and Volga, have about one eighth of their language Finnish, and also some Turcotartarian words: the *Moktanic* is a dialect differing but slightly from the Morduin. 35. The *Teptjerai* are people paying no taxes, who originated from the relics of the Tartarokasan kingdom in the sixteenth century, and who are said to speak a language peculiar to themselves. The arrangement of all these dialects must remain very imperfect; for want of a greater number of specimens of their peculiarities.

36. The *Samogedie* nations are situated north of the Tartars, by whom they may possibly have been driven into their present habitations. Their languages seem to have some affinity with the Caucasian and Lcsagian dialects, and some of them with the Wogulic and Ostiak families; the specimens in the Comparative Vocabularies seem to have been multiplied somewhat too liberally. 37. The *Camashes* are situated on the right of the Jenisei; they are Shamanites or Buddhists; their language seems to be a mixture of several others, and is divided into several very distinct dialects. The *Koibals* have been baptized; they have borrowed some words from the Turcotartarian family. The *Moters* are situated on the Tuba. 38. The *Ostiaks* on the river Jenisei afford us five specimens of languages totally different from those of the *Ostiaks* already mentioned, but nearly connected with each other, so that they may properly be called *Jeniseiostiams*. 39. The *Jukagirs* or *Jukadshirs* are few in number; they are situated between the Jakuti and the Tshutshi; they have some Jakutish words mixed with their language, and some Tshere-*missic*. 40. The *Koriaks* and the *Tshutshi* occupy the north-easternmost point of Siberia; the proper Koriak is spoken on the bay of Penshin; the *Kolymic* on the river Kolyma, the *Tigilic* on the Tigil in Kamtschatka, and the *Karaginic* on the island Karaga; the Tshutshic has been considered as a dialect of the Koriak. 41. The *Kamtshatkans* are a little further south; the *Tigilic Kamtschatkan* is found, however, on the north of the Tigil; the *Srednish* to the west, on the Bolshaia, and the *Jozhnyshic* on the river Kamtschatka, and towards the South Cape. The languages of the neighbouring parts of America, according to Professor Vater, greatly resemble the Tshutshic.

The *Insular* order of the Tataric or Atactic class of languages must be understood as comprehending all the Asiatic islands east of Borneo. 42. The language of the *Curilees* is spoken not only in the principal of these islands, but also in Kamtschatka,

about Cape Lopatka; but in some of the islands the Japanese is spoken. The *Japanese* derive themselves from the Chinese; but their language contradicts this opinion; they have evident traces of Mongol extraction or relationship. The amiable islanders of *Leu cheu* will long be remembered by the British public for the hospitality they showed to the Alceste and the Lyra; their language appears to be related to the Japanese, as might be expected from their situation. *Formosa* was conquered by the Dutch in 1620, but in 1661 it was taken from them by a Chinese pirate: the next year some books were printed in the Formosan language in Holland; the recapture of the island not being yet known there; in 1682, it was finally given up to the Chinese government. 47. The *Moluccan* is considered by Dr Leyden as an original language; that of Magindanao contains some Malayan, Moluccan, Tagalish, and Bugis. The *Tagalish* or *Gala* is the principal language of the *Philippines*, and almost as generally understood in that neighbourhood as the Malay and Hindustanee in other parts; it is allied to the Malayan and to the Javanese, and was probably derived in great measure from these languages; it also resembles in some measure the Bugis. The *Bissayish* is a ruder dialect of the Tagalish. The *Sulu* differs but little from these dialects, being derived from the same sources. The *Bugis* is the language of Celebes; it is supposed to be more ancient than the Javanese; it seems to contain no Sanscrit, but much Malay, Tagalish, and Javanese, and some of the old Ternate or Moluccan; it is written in a peculiar character, and some good poetry is found in it; there is a dialect called the *Mungharar*. The *Bima* somewhat resembles this dialect; it is spoken in the eastern parts of Sumbawa, and the western of Endé or Flores; it is written either in the Bugis or the Malay character; it seems to have a distant resemblance to the language of Orissa: the dialect of *Sumbawa* exhibits some slight variations. A few single words, as *Matla*, the eye, and *Matte*, death, are found to coincide in almost all the islands of the *Pacific Ocean*; the languages of which, notwithstanding their immense distances, seem to differ less than those of the inhabitants of some very small continental tracts; and they might probably be divided into a few well defined families, if our knowledge of them were more complete. The resemblance of *Matte* to the Arabian *Mot*, and the Latin *Mactare*, is probably accidental.

The number of the *AFRICAN* languages is supposed to amount to 100 or 150, and as many as 70 or 80 of them have been distinguished with tolerable accuracy. The population of Africa seems to have been derived from Arabia, and, as some critics think, rather from the southern than from the northern parts; a great number of its present inhabitants are negroes, but these cannot be distinguished from the rest by any infallible criterion. The account given by Ptolemy of the interior part of the country appears to be wonderfully accurate and extensive, although some of his measures seem to be erroneous, and not sufficiently reconcilable with the truth, even by adopting Major Rennell's hypothesis respecting them. It is however remarkable that Pto-

Lemmy followed Hipparchus in extending the eastern coast of Africa to the Ganges, although more correct ideas of its form had been entertained at Alexandria before his time.

The Egyptians demand the priority, in treating of the inhabitants of Africa, from their early connexion with ancient history, both sacred and profane. It is observable that the representations of the old Egyptians have countenances more or less approaching to the negro physiognomy, though the dry bones of the skeleton have that character somewhat less decidedly than they must have had when clothed with the thick lips and flattish noses of the generality of the representations; at the same time there are sculptures of great antiquity, which exhibit features not unlike those of correct Grecian or Roman beauty; and others have a considerable resemblance to the Arabian nation; at present the people of middle Africa, in general, are more or less like negroes, but they are somewhat less dark, and their noses and lips are less peculiar; the women sometimes screamed if Burekhardt made his appearance on a sudden, and called him the Devil, because he was white. The Egyptians are supposed by some writers to have received their civilization from Ethiopia; but there are at present no traces of the remains of high civilization further south than Nubia, except a few scattered monuments about Axum, of no great antiquity. The Egyptians were first called Copts by the Saracens, and their language has been commonly distinguished by the appellation *Coptic*, that is, as written in characters which are principally Greek, and frequently intermixed with a number of pure Greek words; but not a single fragment of Coptic has yet been discovered in this form that is earlier than the establishment of Christianity in Egypt; and it seems probable that the character was introduced by the early Christians at the time of the translation of the Scriptures into Coptic, which is certainly of very high antiquity. The Greek authors frequently mention an Egyptian alphabet of twenty five letters; but no traces of any such alphabet is found in the multitudinous inscriptions or manuscripts that have been preserved by the exertions of the numerous and adventurous travellers who have lately visited the country. (See the article EGYPT, of this *Supplement*.) The Greek words mixed with the Coptic are not considered by the grammarians as incorporated with the language, nor are they admitted into the dictionaries. The genuine language bears very evident marks of great antiquity; its construction is simple and often awkward; and a great number of its words are monosyllables. We have positive evidence of its having remained unaltered, from the time of Herodotus, Plutarch, and other Greek authors, and it affords us the etymology of the name of Moses, and of some other words mentioned in the Scriptures. It exhibits a few coincidences with other ancient languages, but not enough to enable us to consider it either as the offspring or the parent of any of them, except that it gives us something like an explanation of the meaning of some of the Greek particles. Out of 114 original Egyptian words, which are enumerated by the Quarterly Reviewer, in his account of Mr. Townsend's work, there are fifty two that re-

semble the Greek, twenty seven the German and English, eighteen the Hebrew, three the Syriac, two the Arabic, two the Sanscrit, one the Slavonian, and one the Cantabrian. It is, however, probable, that a person more intimately acquainted with the languages of the Arabian family would have been able to find a much greater number of coincidences, since nations, which had so much intercourse as the Jews and the Egyptians, could scarcely fail to have many words in common, even if their languages had been at first completely different; and probably many of the Arabic roots, which are not Hebrew, may be found in the Egyptian. To the Cantabrian word inserted in this enumeration, Dr Young has added five others, in his late essay, already quoted, the whole six being *Berria*, new; *Ora*, a dog; *Guchi*, little; *Oguia*, bread; "Otson," a wolf, whence the Spanish *Onza*; and *Shashpi*, seven: in Coptic, *Beri*, new; *Uhor*, a dog; *Kudshi*, little; *Ork*, bread; *Uonsh*, a wolf; and *Shashf*, seven; whence he infers that "if we consider these words as sufficiently identical to admit of our calculating upon them, the chances will be more than a thousand to one that, at some very remote period, an Egyptian colony established itself in Spain; for none of the languages of the neighbouring nations retain any traces of having been the medium through which these words have been conveyed. On the other hand," he continues, "if we adopted the opinions of a late learned antiquary," General Vallancey, "the probability would be still incomparably greater, that Ireland was originally peopled from the same mother country; since he has collected more than one hundred words, which are certainly Egyptian, and which he considers as bearing the same sense in Irish; but the relation, which he has magnified into identity, appears in general to be that of a very faint resemblance; and this is precisely an instance of a case in which it would be deceiving ourselves to attempt to reduce the matter to a calculation." It may, indeed, be imagined that the Egyptian dominions may formerly have extended to the Straits of Gibraltar, and that Spain may have derived a part of its population from this part of Africa, which approaches so near to it; but it could scarcely have happened that no traces of Egyptian monuments should ever have been found at any distance from the Nile, if that active people had really occupied any considerable portion of the neighbouring continent. The word *Chemistry*, in Greek *Chemia*, is well known to be derived from the Egyptian; it has successively been compared, by the Quarterly Reviewer, to *Chim* or *Chem*, heat; and to *Chem*, secret; the latter is the more probable origin of the two; and a third etymon might be found, if it were required, in the word *Dshem*, or *Ghem*, to find, or *Invention*. The Coptic language has been nearly extinct for about two centuries; but the service has been read in Coptic much more lately in some of the churches; though it has now been almost entirely superseded by the Arabic. The proper Coptic, or Memphitic, which was the dialect of Lower Egypt, is supposed, from a word quoted by Herodotus, to be the most ancient; the Sahidic or Thebaic of Upper Egypt was probably preserved for a longer time, especially in some of the monasteries;

there is a separate version of the principal part of the Bible in this dialect, fragments of which have been published by Mingarelli and Woide; a third dialect, much resembling the Thebaic, is commonly called the Bashmuric, and a fourth, the Oasitic, has been partially made known by Mr Quatremere de Quincy. The Egyptians have left no traces of their language among the people who at present occupy the countries that they inhabited; the Nubian vocabularies collected by Burckhardt contain no Coptic words; the people are of different Arab races, but have acquired peculiar dialects, probably mixed with those of the neighbouring negro nations, of several of which we find specimens in Mr Salt's *Voyage to Abyssinia*. But one of the most learned, as well as the most adventurous and industrious of modern travellers, has remarked some coincidences between the old Egyptian language and that of the Barabras, who are neighbours of the Nubians, and extend to the confluence of the Tacazze and the Nile. The Geez and Amharic have already been mentioned as descendants of the Arabian family; they seem to have introduced some traces of this extraction into several of the neighbouring dialects, probably by the translations of the Scriptures, or by the use of the Koran. Professor Vater has taken some pains to prove that the language of Amhara, the Camara of Agatharchides, is wholly independent of the Ethiopic and Arabian; but in this he appears to be mistaken. It exhibits some slight resemblance to the Sanscrit, in a few instances; thus, *Tshegure* is hair, in Sanscrit, *Tshicura*. Macrizi tells us, that there are, in the whole, fifty Abyssinian dialects; but he has probably exaggerated their number. We have obtained more authentic information respecting them from the collections of Bruce, and of his editor, Murray, and still more lately from Dr Seetzen and Mr Salt. Of the Mek of Dungola, the representative of a long race of the Christian Kings of Nubia, little is now known, except that he is in a great measure dependant on the King of Sennar on the one hand, and has been expelled from a part of his territories by the Mamelukes, on the other. Of the Agows and the Gafats, neighbours of the Abyssinians, and situated on the Bahr el Azrek, as well as the Jewish Falashas, who are scattered over the country, especially in Dembea, we have read much in the historical romances of Mr Bruce, which certainly give a faithful picture of the countries to which they relate, notwithstanding some unaccountable inaccuracies with respect to the personal adventures of the author.

The north of Africa is occupied by inhabitants not much differing in appearance from the Arabs; its three principal divisions are the coast, the country of wild beasts, and the desert. The later Arabs have expelled the earlier Africans from the first division, and partly from the second; the *Berbers* occupy the third, inhabiting principally the Oases, or cultivable islands, scattered through the desert, from Mount Atlas to Egypt, and speaking, as Horneman first ascertained, the same language throughout this vast extent. They were first well described by Leo Africanus; they are probably the remains of the Mauritanians, Numidians, Gætulians, and Garamatians; there is no foundation whatever for the opinion

of some modern authors of celebrity, that their language is derived from the Punic; we even find, from Sallust, that the Numidian language differed from the Carthaginian, and from Valerius Maximus, that it was written in a peculiar character, perhaps the same with that which is found in the inscriptions from Lebeda, now in the court of the British Museum. The language of the *Canaries* considerably resembles the Berber; thus, Milk is *Acho* in Berber, and *Aho* in the Canaries. These islands were discovered in 1330, and afterwards conquered, with some difficulty, by the Spaniards; the inhabitants were a fine race of men, and lived in comfort and tranquillity; and they still present some traces of their original character and condition.

The country between the desert Zaara and the Niger is inhabited by a race of people who have a great resemblance to negroes, but are somewhat different from them. In the east are those of *Sudan* or *Afun*, and *Begirma*; in the west the *Fulahs*; the *Phellatas* are a branch of these, extending considerably to the north east, with a mixture of negroes.

Of the languages of the negroes, strictly so called, many interesting specimens have been collected by the zeal of the evangelical missionaries in the Caribbee Islands, and published by Oldendorp, in his Account of the mission; but they do not afford us sufficient materials to enable us to trace any extensive connexions or dependencies among their multifarious dialects.

There are some points of coincidence between the language of *Madagascar* and those of the Malays, the Philippine islanders, the *Beetjuana* Caffres, and the *Corana* Hottentots; there are also a few words, in many of the African dialects, borrowed from the modern Arabic, not, as Court de Gebelin would persuade us, from the Phœnician: nor can any other of the affinities be very distinctly established.

The *Caffres* have little of the negro character, except the black colour, and less of this as they become more remote from the equator; they are supposed to extend across the whole of Africa, immediately north of the Hottentots, as far as Benguela and Quiloa. The *Hottentots*, with their neighbours the *Bosjemen*, speak different dialects of the same singular language, in different parts of their country. Of that of the *Dammaras*, little or nothing is known. Lichtenstein has classed them as Hottentots; but Barrow, who was better acquainted with them, considers them as Caffres.

Extent :
Bounda

LEICESTERSHIRE, an English inland county. It is bounded on the north by Nottinghamshire and Derbyshire; on the west by the latter county and Warwickshire: on the south by Northamptonshire, and on the east by Rutlandshire and Lincolnshire. It is of a triangular form, and few of its limits are marked by nature, as the rivers Soar and Trent form only a part of its northern boundary, and the river Anker a smaller portion of its western frontier. Its greatest length, from north to south, is 45 miles, and its greatest breadth, from east to west, 35 miles. Its area contains 816 square miles.

It is divided into six hundreds, containing 10 towns, 196 parishes, and 30,649 dwelling-houses. By the census of 1811, the number of inhabitants appeared to be 150,419, viz. 73,366 males, and 77,058 females. The deaths, the year preceding, were, 1366 males, and 1370 females. The baptisms of the same year were 2034 males, and 2024 females; the marriages, 1206. The number of families was 31,480; those employed in agriculture were 11,700; those in trade and manufactures 17,027, and those of neither description 2753.

The towns whose inhabitants exceed 1500 are the following:

Towns.	Houses.	Inhabitants.
Leicester, -	4,683	23,146
Hinckley, -	1,123	6,058
Loughborough,	1,140	5,400
Ashby-de-la-Zouch,	647	3,141
Sheepshead, -	547	3,026
Donnington Castle,	493	2,308
Melton-Mowbray,	422	2,145
Wigston Magna,	388	1,901
Lutterworth,	425	1,845
Market Harborough,	342	1,704
Kegworth, -	313	1,550
Earl Shilton,	310	1,533
Mount Sorrel, -	281	1,502

Face of the
Country.

The county of Leicester may be described generally as a level district, whose undulations are very gentle, and exhibiting but few interesting prospects. The exceptions to this remark are the Charnwood Hills, on the northern part of the county, which rise in an insulated mass, and from the summit of which the rest of the county appears extended in a well-wooded but even surface under the feet. The most lofty prominence of this range of hills (commonly denominated the *Forest*, though it is destitute of trees) is Bardonhill, whose top is 850 feet above the level of the sea. The vale of Belvoir, in which the castle of the Duke of Rutland stands, displays much beauty

of a soft, rather than a romantic and picturesque character.

None of the rivers of this county are considerable streams, nor any of them calculated for the conveyance of commodities except the Soar, for a short distance, but they are abundant, and contribute to increase the beauty and fertility of the district. Their names are, the Anker, Avon, Blackbrook, Deane, Eye, Scalford, Sence, Snite, Soar, Swift, Trent, Willand, and Wreke. The intercourse of the county both in its own different districts and with the surrounding parts of the kingdom, is amply provided for by several navigable canals. One of these connects the town of Leicester with the Grand Junction Canal, in Northamptonshire; another communicates by Loughborough with the river Trent; another from the coal mines near Ashby-de-la-Zouch, passes by Hinckley, and proceeds into Warwickshire; and one is designed to connect Melton-Mowbray with the centre of Rutlandshire.

Though the soil is various, yet, in general, it may be classed under the denominations of either clay or loam, for there are very few portions of it that are calcareous, sandy, or gravelly. The best soil is on the hills, and generally the vallies are a cold clay, very wet in the winter, and with the turf so tender as scarcely to bear the treading of sheep in that season. The soil is naturally productive of the best and most abundant crops of grass, and better fitted for feeding cattle than for arable culture. In consequence of this quality, a very small portion is under the plough, but those parts produce most excellent wheat, oats, and beans; the latter have great celebrity. There are few open fields now remaining, and the quantity of waste land is very small. The productions of the soil are principally from the sheep and cows. Mr Bakewell, whose fame in improving the breeds of all cattle is generally known, has been the means of stocking this county first, and afterwards many other parts of England, with a race of sheep produced by various crosses, that by many farmers is now preferred to every other, and universally known by the name of the *new Leicesters*. They unite perfect symmetry of shape with the smallest possible quantity of bone and offal, and their wool is both fine and abundant. The horned cattle were, in like manner, improved by the lessons of this skilful breeder; and no part of England exceeds Leicestershire either in its beef or in the produce of the dairy. The cheese commonly made is in great request through all the north of England, and the kind called Stilton, from having been first sold in that town, though made near Melton-Mowbray, is perhaps the richest in the world.

Stilton
Cheese.

Leicester-shire.

The process of making it was long kept a secret in a few villages, but is now universally known. Its richness arises from one-half the milk being skimmed, and the cream taken from that added to the other milk, so that the cheese have double the usual quantity of cream in their composition. Bakewell improved, also, the breed of horses to a great extent. In this line there was less room for any extraordinary progress; but his black horses, of the cart kind, originating principally from mares which he brought from Flanders, enabled him to introduce the method of ploughing with two horses abreast, by which much labour in agriculture is saved.

Manufactures.

The manufacture of most eminence in this county is that of Hosiery, which gives employment more or less constant to two-thirds of its inhabitants. The quantity of stockings made here is prodigious, and supplies the greater part of the British dominions, as well as many other parts of the world, with those of an inferior and middling quality. The first frames were invented about 1590, but the first introduced in Leicestershire was used at Hinckley, in 1640. Since that period, many improvements in the machinery of them have been made. At each step in advance, the apprehension of diminishing the labour has occasioned riots and tumults among the workmen, which have been continued to the present time, and recently has embodied them under the denomination of *Luddites*, to the terror of the peaceful inhabitants, some of whom have transferred their capitals and machinery to less turbulent districts. The only other manufactures of consideration are, an extensive one of cotton-spinning and weaving, at Loughborough, and some small ones, of stuffs, at Market Harborough.

Minerals.

In the north-west part of the county there are extensive mines of valuable coal, which supply the inhabitants of the surrounding districts. With them terminate the mines in the direction of the German Ocean to the southward. At Bredon, on the confines, the singular rock, called Bredon Hill, is composed of a most valuable kind of limestone, which forms an excellent cement in water, and which was used for building the pier of Ramsgate.

Antiquities.

The Roman roads are still visible in many parts of the county, though in many instances they have been covered by the more recent highways. The Watling Street road, the Fosseway, and the Via Davana, traversed the county, and have been traced with great accuracy by antiquarians. At Radcliffe, on the Wreke, is an ancient tumulus, generally attributed to the Celts, 350 feet long, and 120 broad. At Leicester, which was a Roman station, are still visible the remains of the architecture of that people, in what is called the Jewry wall, consisting of a mass of stones, brick work, and dilapidated arches, built in alternate courses of brick in three layers, and of stone. Near the town is the vestige of a British Cursus, according to some antiquarians, or of a Roman camp, according to others. At different and distant periods a great number of coins have been discovered, with the names of Titus, Trajan, Dioclesian, Constantine, Constantius, Hadrian, and other Roman emperors. Other Roman antiquities have been found at Rothley, at Wanlip, at Market Har-

borough, at Burrow, and at Cathorpe. The Gothic remains are considerable; those of the Abbey of Leicester, of the Nunnery of Grace Dieu, Ulvestoft Priory, Laund Priory, the Castle of Ashby-de-la-Zouch, the churches of Hinckley and Melton-Mowbray, and the chapel of Market Harborough, all reward the inspection of the antiquarian.

Leicester-shire
||
Leitrim.

In the church of Lutherworth, the pulpit and part of the vestments of the great reformer Wickliffe are still preserved. He was buried there in 1387; but, in 1428, his bones were taken up and burnt, and the ashes thrown into the river, by order of the Council of Sienna. Leicestershire has been the scene of two great military events, which have been the means of transferring the government of England. The first the battle of Bosworth, which terminated the reign and life of Richard III. in 1485, and the other the battle of Naseby in 1645, which led to the death of Charles I., and the subsequent elevation of Oliver Cromwell.

Leicestershire returns but four members to Parliament, viz. two for the county, and two for the borough of Leicester.

The noblemen and gentlemen's seats are very numerous: the most remarkable are, Belvoir Castle, Duke of Rutland; Beaumanoir Park, W. Herrick, Esq.; Buckminster, Sir William Manners; Staunton Harold, Lord Ferrers; Kirkby Park, Sir R. Milbank; Normanton Hall, George Pochin, Esq.; Rothley Temple, T. Babbington, Esq.; Stapleford, Earl of Harborough; Stoughton Grange, G. A. L. Keck, Esq.; Donnington Park, Marquis Hastings; Gossall Hall, Honourable R. Curzon; Stewards Hay, Earl of Stamford.

See Nicholls's *History of Leicestershire*; and *Parliamentary Population Papers*. (w. w.)

LEITRIM is a county in Ireland, in the province of Connaught, bounded on the north by the bay of Donegal and the county of Fermanagh, on the east and south-east by Cavan and Longford, and on the south and west by Roscommon and Sligo. It is about 58 English miles long, and from 7 to 20 broad, and contains 601 English square miles, or 386,560 English acres, divided into five baronies, and seventeen parishes. Half this area or more consists of bog, waste, and water. The centre of the county is in north latitude 55°, and west longitude 7°.

The river Shannon, which enters Leitrim on the Surface, &c. north east from Cavan, about five miles from its source, and soon after flows into Lough Allen, forms, after issuing from that lake on the south, the boundary with Roscommon, on the south-west, till it leaves this county at the village of Rusky. From Carrick on Shannon to Rusky the country is well wooded, fertile, and exceedingly pleasant; but from the southern side of Lough Allen to the northern boundaries, throughout its whole breadth, the greater part of the surface is occupied with mountains, and presents, though not without several exceptions, a very rugged and sterile appearance. The Shannon is the only river of any note; another, the Abhain-Naille, is remarkable for having its source in the lake Killowmawn, situated on the summit of a mountain, called Leacka, into which no streams flow

Leitrim. The principal lake is Lough Allen, near the middle of the western boundary, about nine miles long, and seven miles broad. Lough Melvyn and Lough Gill, though much smaller, deserve to be noticed for the beauty of the scenery on their banks, and the former for its wooded islands and ruins. In these lakes, and also in the Shannon and most of the rivulets, various sorts of fish, the perch in particular, are in great abundance.

There are large tracts of a dark fertile soil incumbent on limestone in the low grounds, but the hills are for the most part covered with a coarse unproductive clay mixed with gravel, and very retentive of water. Below this clay, slate of different colours sometimes occurs. Ironstone, in some places alternating with limestone, is very common; and it was formerly worked to some extent. Coal is found in the mountain Slieb-an-Erin, on the east side of Lough Allen, and has been raised in quantities for some years, but it is not of a good quality, and is employed only in foundries. Pipe-clay and ochre appear in the beds of the rivulets that descend from this mountain. Lead and copper are known to exist in several places; and there is a great variety of clays and marls. Mineral springs, both chalybeate and sulphureous, are not unfrequent, and have been used with very beneficial effects.

About the beginning of the eighteenth century, Leitrim is said to have been almost a continued forest. There is now little wood in it, and no considerable plantations. The proprietors, however, have of late paid some attention to this method of improvement, and several large nurseries have been established for the sale of forest and other trees.

Estates and Farms. This county is in general divided into large estates, and nearly all the great proprietors are absentees. The leases are commonly for three lives or thirty-one years. Agriculture is here in a very low state. The tillage farms are small, seldom exceeding fifty or sixty acres, and these are almost always subdivided among a number of tenants. The plough is very little used. The most common implement is the loy, a kind of spade eighteen inches long, about four inches broad at the bottom, and five or six inches at the top, where it is furnished with a wooden handle about five feet long. The first two crops are potatoes, which are followed by flax, and then oats for one or more years. Clovers and other green crops are unknown in the practice of the tenantry. The county raises grain and potatoes sufficient for its own consumption, but exports very little of either. Its cattle have been much improved by the introduction of English breeds, to which some of those now bred and reared in it are said to be not inferior. There are no considerable dairies, yet a good deal of butter is made throughout the district, and some of this is sent to the market of Sligo. The sheep are of the native race, small, and but few in number.

Population. In 1802, the number of families multiplied by five, gave a population of 76,630, in which, according to Wakefield, the Catholics are as thirty to one. The principal towns are Carrick on Shannon, Carrigallen, Mohill, Ballinamore, and Manor Hamilton, none of which contains more than a few hundred inhabitants. Leitrim, from which the county takes its name, has

been for many years of still less importance, though it is pleasantly situated on the Shannon. There are several bleachfields, and some coarse potteries; and a number of people are employed in weaving. But the linen made here, as well as the coarse woollen goods, is chiefly for the use of the inhabitants themselves. The houses of the lower classes are of the worst description; even the more recently erected farm buildings, including a little barn and cow-house, do not cost more than L.10 or L.12. Turf is their only fuel, and potatoes and oaten bread the chief articles of food, meat being used on extraordinary occasions only; but the people are said to be comfortably clothed. In 1802, wages were only from 4d. to 6d. a-day for cottars, and 6½d. with breakfast and dinner, for occasional labourers, and these rates have not been much altered since. The price of potatoes is from 1½d. to 3d., and of oatmeal from 1s. to 1s. 9d. per stone. Even among the old people the English language is in general use. Leitrim county sends two members to Parliament. See Macparlan's *Agricultural Survey of Leitrim*, and the general works quoted under the former Irish counties. (A.)

LEMONNIER (PETER [CLAUDE] CHARLES), a diligent and accurate astronomer, born at Paris, 23d November 1715, was the son of Peter Lemonnier, of St Sever in Normandy.

His father was a professor of philosophy in the College d'Harcourt, and a member of the Academy of Sciences: he distinguished himself, as a teacher, by his activity in promoting the introduction of mathematical reasoning into the Cartesian philosophy. Under such auspices, the son might have enjoyed facilities for the cultivation of any of the sciences; but he soon showed a decided preference for astronomy, and began to be a practical observer before he was sixteen. In the month of November 1732, Mr Fouchy procured him the use of a mural quadrant of three feet radius, and he soon applied himself with diligence to the determination of the sun's greatest equation,—an investigation which he continued for many years; and in 1741, he found the equation to amount to 1° 55' 31"; a quantity differing only by 7" from Delambre's latest determination.

He presented to the Academy of Sciences, in 1735, an elaborate map of the moon, accompanied by some remarks; and in the month of April of the following year, before he was twenty-one years old, he was made a member of the Academy, in the character of Adjunct Geometrician. He continued to be a constant contributor to its *Memoirs* for more than fifty years. The winter of 1736 and 1737 he passed at Torneo, with Clairaut and Maupertuis, as a member of a committee appointed by the Academy for measuring a degree in Lapland, and he was not less zealous than any of his colleagues in the execution of that arduous undertaking.

He is considered as having effected, in conjunction with Lacaille, a complete reformation in the practical astronomy of France. He entered very early into correspondence with the English astronomers of the day; they had carried their instruments and modes of observation to a higher degree of per-

Leitrim
li
Lemonnier

Wages and
Prices.

Lemonnier. section than their neighbours; and Lemonnier was of great use to the science, in making known to his countrymen the practical methods of Flamsteed, and in introducing the instruments of Graham and Bird. In April 1739, he was made a Foreign member of the Royal Society of London, and for the last twelve or fourteen years of his life, he is said to have been the senior member of the Society. He was the first that introduced the effects of nutation, then lately discovered by Bradley, into the solar tables; and he complained bitterly of Lacaille's injustice, in not giving him due credit for the improvement.

The Duc de Noailles made him known to the King of France, who was fond of his company, and showed him many kindnesses; in 1742, he gave him apartments at the Capucins in the Rue St Honoré, where he continued to live till the Revolution: on another occasion, when he had taken great pains to fix an accurate meridian at St Sulpice, the king made him a present of 15,000 livres, which he expended in the purchase of instruments, as the greatest luxury that he was capable of enjoying.

The places of the stars, which he determined in 1740, served Lalande for the purpose of computing their proper motions, though they differed a little from the results of Bradley's observations. About 1746, he was much engaged in examining the inequalities of Saturn, produced by the attraction of Jupiter: and Euler employed his computations in the theory, which obtained a prize in 1748; each confirming the accuracy of the other. He continued to observe the moon, without intermission, for fifty years, though a small part only of his observations was published.

In the year 1748 he went to England, partly for the purpose of obtaining further information, from a personal acquaintance with the astronomers and opticians resident in London, and partly in order to observe the solar eclipse of that year, in a situation where it would be very nearly annular. He proceeded accordingly to Scotland with the Earl of Morton, accompanied by Short the optician, and they observed the eclipse together at Aberdour, an ancient residence of Lord Morton's in Fifeshire. They obtained their time from the College at Edinburgh, where there was a transit instrument, by means of the flash of a cannon fired from the castle at twelve, and another five minutes after. "The eclipse was so nearly annular, that at the nearest approach, the cusps seemed to want about one-seventh of the moon's circumference to be joined; yet a brown light was plainly observed, both by Lord Morton and myself," says Mr Short, "to proceed or stretch along the circumference of the moon, from each of the cusps, about one-third of the whole distance of the cusps from each cusp; and there remained about one-third of the whole distance of the cusps not enlightened by this brown light, so that we were for some time in suspense whether or not we were to have the eclipse annular with us. During the greatest darkness, the planet Venus was seen at Edinburgh, and other places, by a great number of people, but I did not hear of any other stars being seen. The darkness was not great, but the sky appeared of a faint languid colour." In fact, our mornings and

evenings are always illuminated by a light, which Lemonnier. has acquired more or less of a red tinge in its oblique passage through the atmosphere; and when we have a similar light without the redness, the contrast between the sensation and the memory makes it appear "faint," that is, greenish or grey, instead of white. Mr Lemonnier was particularly anxious to measure the moon's diameter, which "he found $29' 47\frac{1}{2}''$," agreeing precisely with the computed diameter, and not requiring any correction for the supposed effects of irradiation. A similar remark was made by a very accurate practical astronomer in the eclipse of 1820.

In order to verify the position of his mural quadrant, which was of eight feet radius, and made by Bird, Lemonnier felt the advantage of having a moveable one to compare with it, and he procured a block of marble eight feet by six, and fifteen inches thick, turning on an axis, to which he fixed his smaller instrument, of five feet radius, in order to be able to reverse its position. He devoted a considerable portion of his time to the investigation of the laws of magnetism, and especially to the variation of the compass; and he endeavoured to ascertain the effect of the moon's influence on the winds, and on the atmosphere in general.

Lemonnier had long disputed the accuracy of the Parisian base, measured by Cassini and Maraldi, but he was at last convinced that his objections were groundless. He was originally a most zealous friend and patron of Lalande, but afterwards, having taken offence at some slight cause, he refused to see him for many years. In fact, he appears to have been somewhat obstinate and irritable; but he is said to have had genius, zeal, activity, and intelligence, as well as credit in the world, and reputation among men of science. He was a voluminous writer; he had much learning and sagacity, but he often wanted precision in his language and his reasoning. In November 1791, he had a paralytic attack, which terminated his scientific career, though he survived it till the 2d April 1799, when a second stroke carried him off, at Hévil, near Baieux. He was made, in the mean time, one of the 141 original members of the National Institute, as a testimony to the merit of his past labours.

He had married, in 1763, Mlle. de Cussy, a lady of very respectable family in Normandy. He had three daughters; the first married Mr de Parfouru, who was an early victim of the Revolution; the second the celebrated Lagrange; and the third her uncle, Lemonnier the physician, who was also a man of considerable science, and a Member of the Royal Society of London.

From 1735 to 1790, there are very few volumes of the *Memoirs* of the Academy without one or more of Lemonnier's papers; but though not unimportant in the aggregate, they are somewhat uninteresting in the detail. They relate almost exclusively to astronomical observations: eclipses, occultations, appulses, oppositions, and conjunctions; solstices, longitudes and latitudes; with some accounts of astronomical instruments and apparatus. There are also some memoirs relating to the sun's equation and diameter, and on his place, as compared with

Lemmonier. Arcturus; on the motion of Saturn, and on his fifth satellite; on the expansion of wooden measures; on the transit of Venus, and on the diameter and the tables of that planet; on Euler's formula for parallel; on the variation of the needle; on lunar altitudes; on the tides; on horizontal refraction; on Saturn's ring, and on some currents of wind. He also published separately some extensive works, which acquired considerable celebrity.

1. The first was his *Histoire Céleste*, 4. 1711. Comprehending the interval from 1666 to 1685; and containing an account of a transit instrument of Graham's construction.

2. *Théorie des Comètes*, 8. 1743. Including a translation of Halley's work on comets; together with a method of computing the orbit from three observations.

3. *Institutions Astronomiques*, 4. 1746. An improved translation of Keil's Astronomy, which long continued to be the best elementary treatise in the French language. It contains also solar tables, and a variety of other additions derived from observation.

4. *Observations Astronomiques*, Part I. 1751, II. 1754, III. 1759, IV. 1775.

5. *A Letter on the Theory of the Winds*, in Halley's Tables, published by Chappe.

6. *Nouveau Zodiaque, réduit à 1755*, 8. Paris, 1755. Containing thirty-one pages of charts, much more complete than those of Senex, and superseded by some very late publications only.

7. *A History of Astronomy* in the *Traité d'Abrégé* of Fontaine des Crues.

8. *Observations pour la mesure du degré entre Paris et Amiens*, 8. 1757.

9. *Abrégé du Pilotage*, par Goubert, 4. 1766. With additions.

10. *Astronomie nautique lunaire*, 8. 1771.

11. *Exposition des moyens les plus faciles de résoudre plusieurs questions dans l'art de la navigation*, 8. 1772. Employing very generally a table of verse sines; and greatly recommending the use of Gunter's scale for nautical computations.

12. *Essai sur les marées*, 8. 1774. Particularly describing the effects of the tides at Mont St Michel, and on the neighbouring flat sands; including also some considerations on refraction, and on magnetism.

13. *Déscription et usage des principaux instrumens d'astronomie*, fol. 1774. As a part of the collection of *Arts et Métiers*.

14. *Atlas céleste de Flamsteed*, 4. 1776. Revised.

15. *Lois du magnétisme*, 2 Parts, 8. 1776-8. With an elaborate chart.

16. *Traité de la construction de vaisseaux*, par Chapman, fol. 1779. From the Swedish. Said to be less perfect than the translation of Vial du Clair-bois.

17. *Mémoires concernant diverses questions d'astronomie et de physique*, 4 Parts, 4. 1781-4-6-8.

18. *De la correction introduite pour accourcir la ligne sèche du lock de dix-huit pieds*, 8. 1790.

19. *Lettre au sujet d'une éclipse*. Par. 1791. Together with some remarks on navigation, and on the currents of the South Seas; all apparently from the

Memoirs of the Academy. The eclipse, which was observed as annular in China, should have been total, according to the computed distances of the luminaries concerned. (s. 1.)

LEWIS, is the name of an instrument which is indented into a large stone, and has a ring for the purpose of making fast a rope, in order to move the stone, or to act as a stay. It is called in Italian *Ulivella*, in French *La Louve*, in German *Stein Zang*. The lewis consists of three wedges of iron, forming, when put together, a dove-tail. The wedges are inserted into an equal and similar hollow dove-tail excavated in the stone. This hollow dove-tail is made exactly of the form and size of the lewis, and is a figure of six sides; a pair of vertical sides, which are opposite, equal, and parallel, and in form of truncated isosceles triangles; a pair of inclined sides, opposite equal rectangles, equally inclined to the axis of the hole, and not parallel. The top and base of the hole are rectangles parallel to each other, the base being longer than the top. The centre of the base and the centre of the top are in one vertical line. The form of the hole, therefore, is that of an inverted wedge, with the point cut off; it is like a cavity fitted to contain the inverted keystone of an arch. When the iron dove-tail called the lewis is inserted into this hollow dove-tail made in the stone, the ring at the smaller and upper end of the iron dove-tail serves for making fast a rope, for the purpose of raising the stone. The constitution of the substance of timber enables the workman to fix a rope to it by merely inserting a screw or a spike into the log; stone will not admit of these, and is made fast by the contrivance of the lewis. The lewis of the most useful form, and that which is used in Britain, is represented at fig. A, Plate XCIV.; *a* and *b* are two pieces of iron in form of inverted wedges. These pieces are inserted into a quadrangular hole which is made in the stone. The two opposite and shortest sides of the hole are dove-tailed, or, in other words, undercut, as represented at fig. B, which is a vertical section of the hole; *t* is the plan of the hole at top, *o* is the plan of the bottom of the hole. The hole, as represented in the figure, is five inches long at top, and six inches at bottom; the width is one inch, the depth seven inches. Sometimes the width is one and a half inch, and the depth four or five inches. The hole is made of such a size that the lewis fits exactly into it; *a'*, *c'*, *b'*, are transverse geometrical views of the pieces *a*, *c*, *b*; in the transverse view it is seen that the transverse sections of the parts of these pieces that enter the stone are of the same breadth from top to bottom. The piece *c* is represented with a perforation at top, for the purpose of taking out this piece more easily when the lewis is to be unshipped, but the lewis is usually made without this upper perforation. The pieces *a*, *b*, are first introduced into the hole, then is driven in *c*, which may either be a parallelopiped, or it may be a little thicker above, in form of a wedge; the ring *m* is then put on, and the bolt *g* *h* is passed through the holes of the ring and of the three pieces; the bolt enters at *g*, and forelocks at *h*. The tackle by which the stone is to be elevated is hooked on the ring *m*.

Lemmonier
Lewis.

Lewis.

This ring, in cases where a rope is to be passed through it, is bound round with cord, to prevent the rope from being chafed by the iron of the ring.

Piranesi has proposed and figured some other forms of this machine in his *Antichità di Roma*, but they do not appear to be so convenient as the lewis of the common form above described: one of the forms of lewis given by Piranesi is represented at fig. F. The two pieces which constitute the iron dove-tail open and shut by a joint; *n* is a bolt, which is put into the round hole at *p* after the instrument is inserted into the stone; this transverse bolt serves to keep the legs of the instrument spread out, so as to retain the form of the dove-tail. The lewis of the most usual form, represented at fig. A, and a lewis of another form, fig. G, are figured and described in Perrault's *Vitruvius*, lib. x. chap. 2, and in the *Theatrum Machinarum*, tab. XXXV. p. 111. In the lewis, fig. G, the iron dove-tail L has a ring at top, *r*, for receiving a rope; L is put into the dove-tailed hole in the stone, and then the two parallelopipedal iron bolts *c*, *u*, are put in on each side of the iron dove-tail; *c* and *u* are of equal thickness throughout. The top of the hole must not be less than the bottom of the piece L, to the end that L may enter into the hole. The ring must not project beyond the lines which form the prolongation of the inclined sides of the wedge L; for if the ring projected, the pieces *c*, *u*, could not be put into the hole. The hole must be formed so that the machine fit accurately into it.

Uses of the Lewis.

The lewis is used for raising large stones of several tons weight, in the building of harbours, bridges, and other solid fabrics, which, from the forces by which they are assailed, or on account of the long period they are designed to endure, require to be constructed of great masses of stone. Leupold, in his *Theatrum Machinarum*, mentions, that in many churches in Holland the pavement consists of large slabs of stone or marble, each of them the size of a grave, and covering a burying place; these slabs are laid close to one another, and join accurately, so that no lever or crow can be introduced into the joint to raise them; in each of the slabs there is a hole cut in form of a hollow dove-tail, and into this hole a lewis is introduced when occasion requires that the tomb should be opened.

In the construction of harbours, the lewis fixed in a large stone frequently serves to make fast the ropes which stay the cranes. The lewis is commonly used in the docks at London for fixing mooring-rings in the stone: the ring is easily removed when requisite, by unshipping the bolt of the lewis; for this and other reasons it is found more convenient to employ the lewis for fixing rings, than to run the ring-bolt into the stone with melted lead.

The largest stones that have been wrought and moved by the industry of man occur in the buildings of the ancient Egyptians, but it is not ascertained whether their architects employed the lewis.

Piranesi, in his *Antichità di Roma*, describes and figures lewis holes existing in the upper surface of the large stones of the tomb of Cæcilia Metella at Capo di Bove, near Rome. The *forcipes ferrei quorum dentes in saxa forata accommodantur*, mentioned by Vitruvius, lib. x. cap. 2, denote a machine in

the form of nippers, used to effect the raising of stones in the same way as the lewis; but the words seem to indicate a machine different in form from the lewis. Piranesi also observed in some ancient unfinished buildings, stones which appeared to have been raised by another method, namely, by knobs left on the front and side of the stone, to which knobs the ropes were attached. The knobs were taken off when the building was finished.

Vasari relates, in his Account of Brunalesco, that the use of the lewis was revived in Italy by that architect, who was well skilled in mechanics, and who constructed the cupola of the cathedral church of Santa Maria del Fiore at Florence, about the year 1430; the first great cupola that was built in Europe, and which Michael Angelo had in view when he designed the cupola of Saint Peter's. The lewis called Brunalesco's is represented at fig. C. Plate XCIV. Leo Baptista Alberti, a Florentine architect, who lived in 1440, in his *Treatise de Architectura*, mentions the lewis by the Latin name of *Impleola*: he describes the side wedges as having the figure of the letter D, and from that form the machine had its Italian name *Ulivella*, that is to say, Little Olive. Philander of Chatillon, in his *Commentary on Vitruvius*, published at Rome in 1544, gives a figure of the lewis used at Rome in his time, which resembles that used in England, and represented at figure A. In the *Archæologia*, Vol. X. there is a description of holes observed in the crown of the keystones of the abbey church of Whitby, which was built about 1370, in the reign of Edward III. as is supposed. These holes appear to have been lewis holes; they are of the form of an inverted Y, as represented at fig. D, where *w* is the plan of the top of the hole, and *t* the plan of the bottom; the lewis that fitted into these holes would resemble that represented at fig. E: these keystones at Whitby weigh about 1½ ton. (v.)

LEYDEN (JOHN), a celebrated linguist, antiquary, and poet, was born on the 8th of September 1775, at Denholm, a village on the banks of the Teviot, nearly opposite to Minto-house, in the parish of Cavers, and county of Roxburgh. His father was able to trace back his pedigree through a line of shepherds and husbandmen who had long occupied small farms on the estate of Douglas of Cavers, one of whom, Adam Ledan, in Little Cavers, a stern Presbyterian, had been denounced as a rebel in a royal proclamation in 1684. From his second to his sixteenth year, young Leyden lived with his parents in a retired cottage near the bottom of the "stormy Ruberslaw," where he was taught to read by his father's mother, and where he had no companions except the inmates of that rustic dwelling, and no books except the Bible, and such other volumes as are commonly possessed by the Scottish peasantry. His chief delight in the years of childhood was to listen to the tales of martial adventure and supernatural agency, recited by a blind uncle of his mother, and to read such works as the *Metrical Histories* of Bruce and Wallace, the *Poems of Sir David Lindsay*, and the *Arabian Nights' Entertainments*. In his tenth year he went first to school at Kirkcaldy, a distance of two miles from his father's house, and

Lewis
Leyden.

Leyden. there, under three successive schoolmasters, he learned writing, arithmetic, and the elements of Latin grammar. After having spent three years in this manner, he was placed under the charge of Mr Duncan, a Cameronian minister at Denholm, and at the end of two years, not unprofitably employed in this small seminary, he entered the University of Edinburgh in November 1790. Mr Dalzel, then Professor of Greek, has repeatedly stated to the writer of this article, that he had seldom known any young man who at first appeared worse prepared for college, and who so speedily surmounted the disadvantages of imperfect tuition. He had accumulated a great stock of knowledge by a process of study peculiar to himself; but he had not thought it necessary to make himself master of grammatical rules; and, with all his strength and acuteness of mind, he at this time expressed his meaning in terms exceedingly awkward, and in a tone of voice so dissonant and loud as to set his fellow-students in a roar. He attended three winter sessions at the classes for languages and philosophy; applying with extraordinary ardour to every branch of inquiry connected with his academical studies, and to many other pursuits in which none of his instructors could have guided him. The vacations were generally passed in his native wilds among his own relations, with the exception of the summer 1792, when he acted as assistant in a village school at Whitebanklee, or Clovenfords, on Cadon Water, a mountain stream which falls into the Tweed, below Ashiesteel, on the skirts of Ettrick Forest. The charge of the school was left almost entirely to him; but the management of thirty boys and girls, from six to twelve years of age, appeared to be a task for which he possessed no manner of aptitude. Two of his pupils, who were learning Latin, looked up to him with deference and admiration; one of whom did not long survive him, and the other has held various appointments in the church and the universities; but the children in general were in a state of insubordination and tumult, which he endured with a degree of calmness, of which those who knew him in maturer life would have conceived him to be incapable. At this time his appearance was very prepossessing. He was ruddy and fair, with a frame rather delicate than robust, and an expression of great good nature and gentleness in his features.

In November 1793 he entered on the study of Divinity, Church History, and Hebrew, and passed through the usual course of four years' attendance, before he was proposed for trials as a licentiate or probationer of the Church of Scotland. Much of his attention was in the mean time devoted to historical research, to philology, to metaphysical speculations, and to natural history, and medicine. He was a member of various debating societies, in all of which he distinguished himself by the fluency and copiousness of his unpremeditated harangues, rather than by any graceful or polished eloquence. In one of these institutions he contracted an intimacy with Mr Henry Brougham, and with the late Dr Thomas Brown, and Mr Francis Horner, as well as with several other individuals who subsequently attained no inconsiderable distinction. About the same time he formed an

acquaintance with some literary men farther advanced in life, as Mr Thomson, author of *Whist*, a poem, and Dr Robert Anderson, editor of the British Poets, and then supposed to be connected with the *Edinburgh Magazine*,—to which both Leyden and Mr Thomas Campbell, one of his youthful friends, contributed some of their earliest poetical essays.

When he had completed his theological education, he accompanied one or two pupils to St Andrew's in 1797, where he eagerly embraced the opportunity of attending the lectures of Dr Hunter, Professor of Humanity, and of Principal Hill, one of the Divinity Professors. He became also a member of the Theological Society, in which he delivered a number of discourses; one *On the Argument a priori for the Existence of God*; another *On Thanksgiving*; and two *On Regeneration*. He also engaged at almost every meeting in the discussion of some controverted point in divinity or philosophy; and it cannot be doubted that these discussions must often have been highly interesting, when such persons engaged in them as Dr Chalmers of Glasgow, whose speeches differed from most of the others in being generally read. Among the members at that period were Mr Duncan, now Professor of Mathematics at St Andrew's, and Mr John Campbell, now an eminent Counsellor at the English bar. In one respect Leyden felt and acknowledged his inferiority to the students at St Andrew's, namely, in having paid scarcely any attention to mathematics; a study for which he had so little turn, that by his own account he could never comprehend the definition of a straight line, owing to some metaphysical difficulty which nobody could solve to his satisfaction. He appears to have disliked the style of society in St Andrew's, where, however, he acquired more than one of his most valued friends, particularly Dr Hunter and another gentleman of high intellectual capacity, and scientific attainments. From the Presbytery of St Andrew's he received licence to preach in May 1798, and on this occasion he was much disgusted by a vulgar piece of waggonery attempted to be practised at his expence by one of the members who told him, that, as he would be called upon to return thanks after dinner, it was expected that, according to established custom, he should give a specimen of his gifts in prayer, by using a form of words comprehending all the leading doctrines of the Christian faith. When the expected signal was given, Leyden stood up and began to pronounce such a prayer as might have been very suitable for the church; but after having proceeded at some length, and in a very sonorous voice, to enumerate the Divine attributes, he perceived that the company was astonished by this unusual exhibition, and sitting down abruptly in no very placid humour, he was more than half disposed to inflict personal chastisement on the offending individual, with whom he felt enraged, not merely on account of the indignity offered to himself, but for the indecent mockery of one of the solemnities of religion. About this time he returned to Edinburgh, where he frequently preached, not indeed so as to attract popular admiration, but in a manner which satisfied his numerous friends that he possessed a serious, as well as a philosophical mind. Hi

Leyden.

memory was retentive; but in conducting the devotions of a religious assembly, he was apt to be disconcerted by circumstances which would have given him no uneasiness if he had been addressing a learned society.

In the winter of 1798, he attended some of the medical classes, and at this period nearly lost his life, in consequence of his rash and unskilful treatment of a complaint which he believed to be an attack of colic. He swallowed a glass of spirits, in the expectation of receiving immediate relief; but the disorder proved to be *enteritis*, or inflammation of the intestines, and his constitution was so much weakened by venesection, blistering, and evacuations, that he never afterwards recovered the bloom of health. In addition to his duties as a tutor in a family, by which much of his time was engrossed, he had been engaged as a writer in the *New London Review*, and among other articles, contributed those on Horne Tooke's *Diversions of Purley*, on Dr Thomas Brown's *Observations on Zoonomia*, and on Vallancey's *Sanscrit History of Ireland*.

In the summer of 1799 he published a volume, entitled, *A Historical and Philosophical Sketch of the Discoveries and Settlements of the Europeans in Northern and Western Africa, at the Close of the Eighteenth Century*. This interesting piece (an octavo of 442 pages) was written in about six weeks, while the author was in bad health, and at a distance from books; but it exhibits proofs of extensive information, as well as of sound reflection. In the course of the autumn he engaged to publish *The Complaynt of Scotland*, a very rare anonymous work in the Scottish language, written early in the sixteenth century. It did not appear for nearly two years; but the preliminary dissertation, extending to nearly 300 pages, as well as the notes and glossary, indicated a compass of antiquarian lore, and a depth of research in various other unfrequented walks of erudition, which could not easily be rivalled. He also displayed great acuteness and ingenuity in attempting to prove, from internal evidence, that *The Complaynt* was the production of Sir David Lindsay.

Through Mr Richard Heber, to whom he was introduced by Mr Constable, he became acquainted with the most distinguished literary characters in Edinburgh, and among others, with Sir Walter Scott, who at this time was engaged in collecting the ancient traditionary rhymes published in the *Minstrelsy of the Scottish Border*; a collection which Leyden contributed largely to enrich, both by recovering unedited fragments of antiquity, and by communicating imitations written in the spirit and manner of the age of chivalry; as well as by furnishing materials for many of the notes, and particularly for the introduction to the tale of *Tamlane*, containing a learned dissertation on the Fairies of popular superstition.

In the year 1800, a plan was formed to establish him assistant and successor to the minister of his native parish, but it failed in consequence of the reluctance of the incumbent to agree to an arrangement on which the heritors and parishioners had set their hearts. Soon afterwards he was anxious to obtain the Professorship of Rhetoric and Belles Lettres

in Edinburgh; but here also he was doomed to experience a disappointment.

Leyden

About this time he made two successive tours through the Highlands, and collected much curious information, which was once intended for publication. He wrote several poems founded on the remains of Celtic story, two of which have been inserted in the *Border Minstrelsy*. In 1801 he also contributed to Lewis's *Tales of Wonder*.

The year 1802, the last which he spent in Scotland, was one of the busiest of his life. About the beginning of the year, he had carried through the press nearly half a volume of an enlarged *Account of the Progress of Discovery in Africa*. At the same time he engaged to conduct the *Scots Magazine* on an improved plan, and the volume for that year contains many articles furnished by him and by another eminent orientalist, the late Dr Alexander Murray. He was also employed in correcting the papers of the Highland Society for publication; and he edited a volume entitled, *Scottish Descriptive Poems, with some Illustrations of Scottish Literary Antiquities*, containing *Clyde*, by John Wilson, schoolmaster of Greenock,—*Albania*, addressed to the Genius of Scotland,—*The Day Estival*, by Alexander Hume, and *Poems*, by William Fowler. Early in this year, he offered to the African Society to explore the interior of those obscure and inhospitable regions in which so many Europeans have perished. His friends, alarmed at this apparently fatal resolution, became eager to obtain for him an Indian appointment, that might give him access to the treasures of Eastern learning, which his past attainments peculiarly qualified him to appreciate. Through the interest of Mr William Dundas, he was nominated Assistant Surgeon, and though it was privately stipulated, that, on his arrival in India, he was to devote himself chiefly to literary inquiries, he could not be permitted to go out as a passenger in that capacity, without producing a surgeon's diploma, and undergoing an examination before the Medical Board. He had attended many of the medical classes, but he had hitherto paid little attention to the practice of surgery, and it was therefore necessary to prepare himself for passing through the strict trials prescribed by the College of Surgeons. It reflects no slight credit on his capacity and application, that he accomplished this task within six months. He was not equally successful in procuring the degree of M. D. from the University of Edinburgh; but having gone to St Andrew's with certificates of his character and regular education, and having satisfied the *Senatus Academicus* at a private examination, as well as by reading several exercises prescribed to him in the Latin language, that degree was conferred on him there, on the 7th August 1802. While he was occupied in these unpoetical avocations, he continued at every interval of leisure to court the inspiration of the Muses, and he gave the finishing hand to the *Scenes of Infancy, descriptive of Teviotdale*, a poem which had been partly written before, but which was now enlivened by some of its most touching passages, and left for publication in the hands of Dr Thomas Brown, who, in the revision of the sheets, suppressed a number of verses

which the author conceived ought to have been retained.

Leyden spent the winter in London, having narrowly escaped the misfortune of sailing in the Hindostan, which was wrecked in its passage down the Thames. He sailed from Portsmouth in the *Hugh Inglis*, 7th April 1803, and soon after his arrival at Madras, was attached as Surgeon and Naturalist to the Commission for Surveying the Districts of the Mysore, in which capacity he was expected to turn his attention, not only to the natural history of the country, but to the manners, institutions, and language of the inhabitants. His constitution had nearly sunk under the labours to which he subjected himself, and he was under the necessity of removing to Prince of Wales's Island. Here he was befriended by the governor, Mr Dundas, and here too he procured the chief materials of the *Essay on the Languages and Literature of the Indo-Chinese Nations*, contained in the 10th volume of the *Asiatic Researches*.

He removed in 1806 from Prince of Wales's Island to Calcutta, where, through the favour of the Governor-General, Lord Minto, he was appointed one of the Professors in the Bengal College, from which station he was soon transferred to the office of a Judge of the Twenty-four Pergunnahs of Calcutta. The income attached to this charge was applied chiefly in purchasing manuscripts, and rewarding the native teachers whose instructions he solicited; and all his leisure hours were spent in the eager investigation of the languages, the laws and history of the East. In 1809 he was appointed a Commissioner of the Court of Requests in Calcutta, and in the end of the following year, having resigned this office, he obtained the office of Assay Master of the Mint. Soon afterwards he was required to attend Lord Minto upon the expedition to Java, that he might be employed in collecting information with respect to the learning and institutions of the native tribes, and that the Governor-General might enjoy the benefit of his services in negotiating with the local authorities, and in adjusting the future government of the country. After the British troops took possession of the city of Batavia, he ventured rashly into an ill-aired library, supposed to contain many Indian manuscripts,—and on leaving it, was immediately seized with a fever, which proved fatal three days after its accession, and a few days before the conquest of the island was completed. He died on the 21st August 1811.

A very high tribute to his memory was paid by Lord Minto, on occasion of a visitation of the College of Fort-William, after his Lordship's return from the conquest of Java.—“To speak of all that Dr Leyden had already performed, especially in the prosecution of Asiatic learning,—to compute the treasures which his incomparable genius, urging and sustaining his invincible powers of mental labour, presented the fair promise of acquiring and accumulating, would be to relate a history of the short, but memorable

life he was allowed to live, and to expatiate into the yet more ample fields of inquiry of which he had projected the survey. I need not remind those who hear me of the zeal he had long nourished, for exploring the philology of the more eastern regions of Asia; of the first steps he had already made in the prosecution of that purpose, by the construction of vocabularies, but above all, by methodising and reducing into system the classification of the various languages spoken on the continent, intermediate between India and China; the various kingdoms and districts of which, as they recede from each of these extreme points, appear, with some relation to their local approximation, or to historical affinities, gradually to have blended and assimilated their respective languages into compound dialects, partaking of both the distinct and primitive tongues. To this just and authorized tribute to the literary merits of Dr Leyden, I must yet add a personal testimony, prompted by personal experience, to virtues of a higher class, neither connected with the talents and toils of a student, nor so uniformly the companions of learned reputation, as it would be natural perhaps to wish, and to expect. But I speak it in the presence of many who can attest it with myself, that, founder as he was of his own fortunes and reputation, and climbing by many laborious steps from the lowest stage of social life, to an eminence, which many cannot even maintain, though placed yet higher by their birth; no man, whatever his condition might be, ever possessed a mind so entirely exempt from every sordid passion, so negligent of fortune and all its grovelling pursuits,—in a word, so entirely disinterested,—nor ever owned a spirit more firmly and nobly independent. I speak of these things with some knowledge, and wish to record a competent testimony to the facts, that within my experience, Dr Leyden never, in any instance, solicited an object of personal interest, nor, as I believe, ever interrupted his higher pursuits, to waste a moment's thought on those minor cares. To this exemption from cupidity was allied every generous virtue worthy of those smiles of fortune which he disdained to court; and amongst many estimable features of his character, an ardent love of justice, and a vehement abhorrence of oppression, were not less prominent than the other higher qualities I have already described.”

Sir John Malcolm bears testimony, in terms equally strong, to the purity, disinterestedness, and independence of his character, as well as to the indomitable perseverance and ardour with which he devoted himself to literary and scientific acquirements; and, after adverting to some rather unpleasant oddities of manner, “How trivial,” he adds, “do these appear, at a moment when we are lamenting the loss of such a rare combination of virtues, learning, and genius, as were concentrated in the late Dr Leyden.”

See *Edinburgh Annual Register* for 1811; and *The Poetical Remains of the late Dr John Leyden*, with *Memoirs of his Life*, by the Rev. James Monton. 8vo. London, 1819. (c. c. c.)

Liberty of
the Press.

THE task of pointing out which of the acts capable of being committed by the press it would be expedient to prohibit under penalties, we trust will be found to be greatly diminished, by what we have already established in the articles GOVERNMENT and JURISPRUDENCE.

Nature and
Objects of
the Inquiry.

There is scarcely a right, for the violation of which, scarcely an operation of government, for the disturbance of which the press may not be employed as an instrument. The offences capable of being committed by the press are indeed nearly co-extensive with the whole field of delinquency.

It is not for that reason, however, necessary to give a separate definition for every such violation or disturbance, for that would be to write the penal code over; first describing the violation as produced in other cases, and then describing them anew for the case in which the press is the particular instrument.

If, for the prevention of the violation of rights, it were necessary to give a separate definition for every instrument which might be employed as a means of producing the violation, the penal code would be endless. In general, the *means* is an immaterial circumstance. The violation itself, and the degree of alarm which may attend, are the principal objects of attention. If a man is put in fear of his life, and robbed of his purse, it is of no consequence whether he is threatened with a pistol or a sword. In the definition of a theft, of a fraud, or a murder, it is not necessary to include an account of all the sorts of means by which these injuries may be perpetrated. It is sufficient if the injury itself is accurately described. The object is to prevent the injury, not merely when produced by one sort of means or another sort of means, but by any means.

From these illustrations it sufficiently appears, that if an accurate penal code were composed, defining the violations of rights, and disturbances of the operations of government, to which penalties were to be annexed, every offence capable of being committed by the press would be defined without mentioning its name. It is no less evident, that if we include in the term *libel*, as, to the great encouragement of confusion, is generally done, all the offences capable of being committed by the press, we include in the definition of libel all the definitions of the penal code.

As far as persons and property are concerned, the general definition of the acts by which rights are liable to be violated, has been held sufficient; and has been regarded as including not less the cases in which the instrumentality of the press has been employed, than those in which any other means have been employed to the same end. Nobody ever thought of a particular law for restraining the press on account of the cases in which it may have been rendered subservient to the perpetration of a murder or a theft. It is enough that a law is made to punish

him who has been guilty of the murder or theft, whether he has employed the press or any thing else as the means for accomplishing his end. Liberty of
the Press

There can be no doubt, however, that the press is an instrument peculiarly adapted for the commission of injuries against *reputation*, and for effecting disturbance to the operations of *government*, while it has no peculiar adaptation for the commission of other offences. Here, too, it is equally certain there is the greatest disposition to restrain the press within improper limits. It is demanded of us, therefore, upon this part of the subject, to enter into greater detail.

We are then to inquire, in the first place, what are the acts of the press with respect to *private reputation*? and next, which are the acts with respect to *government*, which it is desirable that punishment should be employed to restrain?

Agreeably to the principles which have been already considered in the article JURISPRUDENCE, no act can be regarded as an offence with respect to an individual, which is not a violation of some of his rights. Offences
the Press
with respect
to Private
Rights

In considering the rights which ought to be established with respect to *reputation*, one proposition may be assumed, that every man should be considered as having a right to the character which he deserves; in other words, to be spoken of according to his actions.

In what manner the definition of this right, which would form a part of the civil code, should be expressed, is not now the question; but it is evident that no peculiar difficulty belongs to it. As words, not thoughts, are the object of legal cognizance, the right can only have respect to security against certain words;—words imputing to the individual actions which he has not performed, or a disposition to actions, of which disposition there is no evidence.

Suppose that one man has instituted a suit against another, for the offence of having violated, through the press, his right to all the reputation he deserves. In his ground of complaint he must affirm that the man has imputed to him either the performance of actions which he did not commit, or a disposition to certain actions, of which disposition no evidence can be given.

The words are produced; and the first question is, whether they do or do not impute the actions which, in the complaint or bill of accusation, they are alleged to impute?

It is to be observed, that they who oppose the attempt to define the offences, which, for shortness, we call the *offences of the press*, make use of such occasions as this to raise their objections. How, they ask, can all the forms of expression be defined, by which the imputation of such and such actions may be either more openly, or more covertly conveyed?

It is very evident that the question on such an occasion, whether the words do or do not impute such

Liberty of
the Press.

or such actions, is a question of fact. The law says, that such and such actions shall not be imputed, defining the actions. Whether such and such a man has imputed such actions, either by one set of words or another, is a question of fact.

The law, when it said that such and such acts should not be imputed to a man, could not determine whether A, who is accused by B of having imputed to him one of these acts, did so or not. That is to be determined by evidence bearing upon the fact. One, and in general the main article of that evidence, are the words which have been used. What is the import of these words; or, which comes to the same thing, what is the degree of proof involved in them, is to be determined, as all questions respecting the weight of evidence are in each instance to be determined, by the tribunal before which the accusation is brought. The interpretation of words rests upon the same footing in this as in all other cases, that, for example, of a Will. The law determines that whatsoever disposition a man has made with respect to his property, shall take effect after his death. But whether A has left his manor of Dale to B, is a matter of fact to be determined by evidence applying to that particular fact; principally by that arising from the words of the will.

It may still be argued by persons who do not easily renounce an opinion to which they have once given their support, that even the actions, the interpretation of which, or that of the disposition to which the legislature means to prohibit, cannot be defined.

This, however, is a position which it is impossible long to maintain. Some actions it is hurtful, others it is not hurtful, to a man, if he is believed to have committed, or to have a disposition to commit them. Evidently it is by imputation of the first sort alone, that any right with respect to reputation can be infringed.

The acts which a man receives injury from being believed to have committed, or to be disposed to commit, are either those to which the law has annexed penalties, or those to which the penalties of public disrepute and dislike are annexed.

With respect to those acts to which the law has annexed penalties, as theft, murder, perjury, and so on, it will not be pretended that there is any difficulty; the law has already defined them, or ought to define them, and they may be included with perfect precision in a few words.

Those acts which it is hurtful to a man, solely on account of the disrepute and dislike which they produce, to have it believed that he has committed them, may also be with sufficient accuracy determined.

The ends to be attained by punishment are, reparation to the individual to whom injury has been done, and prevention of similar acts in future.

In the idea of all punishment, effectual reparation to the injured individual is a necessary and essential ingredient. Suppose, then, it were declared by the legislature, that the imputation falsely of all acts, hurtful to the person against whom the imputation is brought, by reason of the disrepute and dislike which attach to him by whom such acts are suppo-

VOL. V. PART II.

Liberty of
the Press.

sed to be committed, shall be punished at least by reparation to be made to the party injured; the word *hurtful* is to this purpose perfectly precise. It would remain with the complainant to show what kind and degree of injury he had received; which is a matter of fact, to be estimated in each instance from the evidence adduced, by the tribunal before which the question is brought. If the injury sustained is a pecuniary injury, the question coincides exactly with the question of damages, decided regularly, in English courts, as a question of fact by the jury.

Injuries of the kind which we are now considering can affect a man only in two ways; either, as stated above, by lessening the pecuniary value which he might otherwise have enjoyed; or, secondly, by lessening the marks of respect and affection which he would otherwise have received. What the loss is, in this latter instance, is also evidently a question of fact. It has nothing, therefore, to do with the legal definition of the offence, the business of the legislature. It is a question, which, like all other questions of fact, must of necessity be determined upon evidence by the tribunal before which it is brought. It is no doubt a question of delicacy, and considerable difficulty, because the evidence must often consist of very fine and minute circumstances, which can seldom be precisely ascertained. But this is not the only class of judicial questions, the determination of which depends upon such evidence as it is very difficult accurately to collect and to weigh.

What it is of greatest importance, on this occasion, to remark is, that all the difficulty lies in the matter of fact. There is no doubt or obscurity in the law, which says, that for whatsoever hurt a man has sustained through actions or dispositions falsely imputed to him, he shall receive compensation. Difficulties, however, arising either from the complexity of the matter of fact, or the obscurity of the evidence, no legislature enactments can prevent. These are committed to the skill and fidelity of the judge.

One question for the legislature we have not yet considered; and that is, the compensation which can be made to a man for the diminution of those marks of respect and affection which he would otherwise have received. Let us suppose that a soldier has been accused of cowardice, in such a manner as to create a general belief of the truth of the accusation; that a man of honour has been accused of mendacity, or of some of those irregular propensities to which the horror of the public is attached; it is evident that money is not an appropriate compensation for injuries thus received.

When a man, through the offence of another, has been deprived of a certain amount of money, or of money's worth, we say that he has received compensation, when he is placed in the same situation in which he would have been if the offence had not taken place.

According to this idea of compensation, a man, against whom an unfavourable opinion has been created by the act of another man, has received compensation, when he is placed in the same situation with regard to the opinion of those with whom he is connected, as if that act had not taken place. This,

L I

Liberty of
the Press.

therefore, is the object which it ought to be the endeavour of the legislature to effect.

One expedient is perfectly appropriate. It is, that the man who has falsely propagated an unfavourable opinion with respect to another, should be made to do whatever is in his power to remove the impression he has made. To this end, he should publish the sentence of the judge, declaring that the action, or disposition which he had imputed to the individual injured, he had imputed to him falsely. He should at least be made to publish it in every way in which he had published the imputation. Frequently a more extensive publication might be required.

In most cases, it will be allowed, that this much would suffice. It may, however, be affirmed, that often the impression would be too profoundly struck, to be effaced by a mere knowledge of the sentence of the judge. In such cases, something more in the way of compensation would be required. On this, it is of importance to be observed, that if the impression produced by an imputation, which, after solemn inquiry, the judge has declared to be false, should not, by that declaration, be completely effaced, it implies necessarily one of two things; either that the public have evidence of the truth of the accusation, which was not adduced to the judge, and then the remaining impression is not owing to the imputation which the judge has condemned, but to the evidence; or, secondly, that the public mind is in a state of gross ignorance and imbecility, capable of forming opinions, even on the clearest subjects, not only not according to evidence, but in opposition to it. If the public mind, however, is in such a deplorable condition, it is the fault of the legislature; and for the rectification of this evil, the best course undoubtedly is, to take effectual measures for the instruction of the people, which instruction would soon place them beyond the danger of such contemptible as well as mischievous delusions. In the mean time, if something more than the publication of the sentence of the judge were necessary to restore a man to that degree of consideration of which the false imputation had deprived him, governments have numerous ways of raising the consequence of individuals; and no legislature would be at a loss for a gradation of expedients suited to the scale of demand.

We have now illustrated that part of this question which regards compensation to the injured individual. It remains to inquire what is best to be done in this case, for the attainment of the other object of punishment, namely, the prevention of similar offences in time to come.

To devise a punishment sufficient to prevent an offence, is to provide a motive sufficient to counteract the motive which leads to the offence. We have hence to consider what are the motives by which men are incited to make false imputations on the characters of others.

These motives may be of three different sorts. A man may derive *pecuniary profit*, he may derive *comparative distinction*, or he may satisfy his desire of *vengeance*, by blackening the character of his neighbour.

Liberty of
the Press.

In the case in which a man has by calumny wrongfully intercepted the pecuniary receipts of his neighbour, the obligation of making satisfaction to the party injured would, it is obvious, alone suffice, provided the machinery of the laws were sufficiently perfect, to render the execution of them certain. Seldom would any man calumniate his neighbour, for the sake of placing £20 in his own pocket, if he were sure that next day, or next week, he would have to restore it, with all the profit which might have been made by the use of it, and with the disgrace besides of having committed an action which other men abhor.

Sometimes, however, a man may derive pecuniary profit from calumniating persons whom he has not by that means deprived of any pecuniary advantage; by the sale, for example, of a slanderous publication; when the satisfaction due to the individual may not be of a nature to counteract the motive which leads to the offence. The expedient in this case, also, is sufficiently obvious, and sufficiently simple. It is necessary to ascertain the whole of the gain which has been made by the offender, and to take it away from him. This, together with the satisfaction which he ought to make to the injured individual, would, if it were certain, create a surplus of motive to abstain from the injurious act.

In both of these cases, if the execution of the law is uncertain, an additional punishment may be necessary, sufficient to compensate for the chance of escape. The allowance to be made on this score must depend upon the imperfection of the laws; while one important fact is to be kept in remembrance, that as severity of punishment, beyond a certain point, is increased, certainty of execution is diminished. The true expedient, therefore, is to render the machinery of the laws so perfect, that the penalties which they denounce may always be sure of execution; and then hardly any thing beyond compensation to the individual, and the abstraction of any additional gain which might have been made by the propagation of slander, would be necessary to repress all offences against the reputation of others, to which the motive was constituted by pecuniary gain.

The two remaining cases are still more simple. If a man propagates a falsehood, for the sake of injuring the character of a man by whom his own consideration is eclipsed, it is only when he expects to obtain by that means a permanent advantage. If he knows that immediately the law will take its hold upon him; that he will be compelled to re-elevate the character of his neighbour, and to proclaim his own disgrace, he will see that, to attempt depressing the character of another man by calumny, is the very worst of all expedients, for giving a comparative elevation to his own. The same is the result in the case where vengeance constitutes the motive to injure the reputation of another. To render this proposition manifest, the most obvious illustration will suffice. No man, to gratify his malignity to another person, would kill his ox or his ass, provided he were sure that immediately he would be obliged to make him full satisfaction; and instead of injuring the man whom he hated, to injure only him-

Liberty of
the Press.

self. No, the rudeness and inefficacy of the law, holding out a chance of escaping the duty of making reparation, is the sole origin and cause of all offences of this description; and if the law were placed in a state but approaching perfection, hardly any thing beside the obligation of making satisfaction would be necessary to repress the whole of this order of crimes.

We have now made considerable progress in this important inquiry. We have ascertained, we think, with sufficient evidence, all that is necessary to be done for preventing injuries to the reputation of individuals; provided the rights of reputation are, by the civil code, not made to extend beyond the boundaries of truth. Whether or not they ought to extend farther, and individuals ought to be protected from the disclosure of acts which they may have committed, is, we confess, a question highly worthy of solution; upon which, therefore, before we proceed to any of the subsequent topics, we shall offer the following reflections.

There can be no doubt that the feelings of the individual may be as painful, where actions of a disreputable nature are truly, as where they are falsely imputed to him. It is equally certain that no painful feelings ought to be wilfully excited in any man, where no good, sufficient to overbalance that evil, is its natural consequence.

We have already shown, that reputation is injured by the imputation of acts of two different descriptions; first, those to which the law annexes penalties; secondly, those to which disrepute and the dislike of others are annexed.

With respect to those acts to which the law annexes penalties, there is no room for uncertainty or dispute. Unless the law is a bad law, which ought to be repealed (this, we confess, constitutes an exception, and one, which, in very imperfect codes, extends a great way), the law ought not to be disappointed of its execution. The man who gives information against a murderer, or a thief, by the press, or without the press, renders a public service, and deserves not punishment but reward.

It appears, therefore, that the question, whether a man ought to be protected from the imputation of actions which he has really committed, refers solely to those acts which, without being punishable by the law, are attended with disrepute; acts, in other words, which the members of the society disapprove and dislike.

The prospect of the immediate and public exposure of all acts of this description, would be a most effectual expedient to prevent their being committed. Men would obtain the habit of abstaining from them, and would feel it as little painful to abstain, as at present it is to any well educated person to keep from theft, or those acts which constitute the ill manners of the vulgar. The fable of Momus has always been understood to carry an important moral. He found grievous fault that a window had not been placed in the breast of every man, by which, not his actions alone, but his thoughts, would have been known. The magnanimity of that Roman has been highly applauded, who not only placed his residence in such a situation that his fellow citizens

Liberty of
the Press.

might see as much as possible of his actions, but declared a wish that he could render open to the eyes of all his breast as well as his house.

If the hatred and contempt of the people, therefore, were always rightly directed, and rightly proportioned; if they never operated against any actions but those which were hurtful, either to the individual himself, or to others, and never, but in the degree in which they were hurtful, the case would be clear; the advantage which would be derived from the true exposure of any man's actions of any sort, would exceed beyond calculation the attendant evil. The great difficulty of insuring the practice of morality, in those numerous and highly important cases, to which the legal sanction, or the security of pains and penalties does not extend, consists in the want of a motive always present, and powerful enough to counteract the temporary motive which urges to the momentary offence. That motive almost every man would derive from his knowledge that the eyes were upon him of all those, the good opinion of whom it was his interest to preserve; and that no immoral act of his would escape their observation, and a proportionate share of their hatred and contempt. It is in this view that the aid of religion has been sometimes regarded as of importance to morality; suggesting the idea of a high and constant observer. All motives, however, are feeble, in proportion as the pains and pleasures upon which they depend are distant, and vague, or uncertain. Divines agree with all other men in complaining of the trifling effect of religious motives upon the lives of the greater number of men. From the nature of the prospect on which these motives depend, they were necessarily as feeble as they have so often been described. Such is not the case with the motives arising from the sentiments which we know we shall inspire in the breasts of our fellow creatures. It is a matter of daily and incontrovertible experience, that these are among the most powerful which operate upon the human mind. The soldier rushes upon death, and endures all the hardships and toils of his cruel profession, that he may enjoy the admiration, and escape the contempt, of his fellow men. On what else is founded the greater part of all the pursuits of mankind? How few, even of those who toil at the meanest occupations, but exert themselves to have something for show, something to make an impression upon the eyes of those who surround them? The very subject of the present inquiry derives from this source the whole of its importance. The value of reputation is, indeed, but another name for the value which we attach to the favourable and unfavourable sentiments of our fellow men.

It is, however, true, that their unfavourable sentiments do not always fall where they ought, and this, we confess, is a consideration of the highest importance. It very often happens that men's antipathies are excited to actions from which no evil ensues, either to him who performs them, or to any body else. If any man derives a pleasure from such actions, it is to limit his sphere of innocent enjoyment, to debar him from them. And if the press exposes him to the antipathies, the hatred, and contempt of his fellow-creatures, on account of those actions, it produces

Liberty of
the Press.

an evil, uncompensated by the smallest portion of good. If an Indian Brahman were known to have eaten, even when starving, a morsel of food which had been prepared by a Christian, the consequences to him would be dreadful. Where the Roman Catholic religion is in vigour, a man who should indulge himself in animal food on forbidden days would be regarded with horror. The use of wine, however moderate, would render a Mahomedan execrable to the whole of his tribe.

This misdirection of the favourable and unfavourable sentiments of mankind, in other words, this perversion and corruption of their moral sentiments, has, in by far the greater number of instances, been the work of priests, contriving the means of increasing their influence. In some very important instances, such, for example, as the prejudices of birth, at one time so powerful in Europe, as to make ineffable contempt the lot of the low, the highest veneration that of the man of elevated birth, the perversion of the moral sentiments, is evidently the work of the aristocratical class, securing to themselves a more easy dominion over the rest of their fellow creatures. It is, therefore, evident, that where antipathies, religious or aristocratical, should prevail, the press would be hurtfully employed in giving notoriety to the facts which would expose a man to the operation of either.

We have now ascertained the cases in which it would *not* be good that men should be protected from the declaration of truth by the press, and also the cases in which it *would* be good that they should be so protected.

What, upon this view of the subject, would be desirable, is sufficiently clear. It would be desirable that, in the one set of cases, the declaration should be allowed, in the other it should not be allowed. Are the two sets of cases, however, capable of being accurately distinguished?

If the comparison is made with any attention, it will not be difficult to determine that the evil to be incurred by the loss of truth in the set of cases in which the declaration of it would be useful, is much greater than that which would arise from permitting the declaration in the cases in which it would be hurtful.

In the first place, the set of cases in which the declaration would be useful are much more numerous, and much more important, than those in which, in any tolerably civilized state of society, it would be hurtful. Those in which it would be useful embrace the whole field of morality, all those acts, the performance of which, on account of their singular importance, has been elevated to the rank of virtues. Every body believes and proclaims, that the universal practice of the moral virtues would ensure the highest measure of human happiness; no one doubts that the misery which, to so deplorable a degree, overspreads the globe, while men injure men, and instead of helping and benefiting, supplant, defraud, mislead, pillage, and oppress, one another, would thus be nearly exterminated, and something better than the dreams of the golden age would be realized upon earth. Toward the attainment of this most desirable state of things, nothing in the world

is capable of contributing so much as the full exercise of truth upon all immoral actions,—all actions, the practice of which is calculated to lessen the amount of human happiness. According to this view, the justice of which it is impossible to dispute, the evil incurred by forbidding the declaration of truth upon all immoral actions is incalculable. That which would be incurred by the antipathies of misguided minds against actions innocent in themselves, nobody, we should imagine, would so much as think of placing in comparison.

In our own country, for example, the classes of actions which, though they injure nobody, expose a man to the unfavourable sentiments of others, are not numerous. The number of persons who would be exposed to inconvenience on account of the declaration of truth, in regard to them, would be small in comparison with those who would benefit by its declaration, in the case of all really hurtful acts.

It is, indeed, important to be observed, that a comparative smallness of number is necessarily implied in the supposition of injury from any unfounded antipathy. Those who share in the antipathy, of course, abstain from the action. And unless the antipathy were so general as to include almost the whole of the society, it would lose its injurious effect. Besides, all the injury which can be done to the individuals against whom truth would in this manner operate injuriously, would be, to make them abstain from the acts which were thus condemned.

Another thing to be considered is, that the whole of the evil arising from the exercise of truth is dependent upon an accidental circumstance, capable of being removed upon a mental disease, requiring to be cured; of which, of course, the legislature ought to undertake the cure, and toward the cure of which truth is likely to operate as the most effectual of all expedients. If any considerable inconvenience were experienced from exposure to unfounded antipathies by publications of truth, the groundlessness of these antipathies could not fail to be so often canvassed, and made to appear, that at last it would become familiar to the multitude, and the antipathies would expire.

It clearly, therefore, appears, that, if the cases in which the declaration of truth would expose to unfounded prejudices could not be clearly defined, and separated from the cases in which the declaration would be salutary, the rule of permitting truth ought to be universal. But though we perceive, that, to a considerable extent, there are cases, in respect to which it would be vain to hope for agreement in drawing the line of distinction between what is hurtful and what is not, we are persuaded that principles might be laid down in which all would agree, and which would serve to mark out certain cases for exception with sufficient exactness. If any such cases could be separated, either of actions which, though injurious to nobody, excited antipathies, or of facts, as those of birth, for which, though a man was in no respect worse, he might be regarded as worse, the exercise of truth, with regard to them, might, on the express ground of these being actions innoxious, or facts which ought to be

Liberty of
the Press.

Liberty of the Press. of no importance in the estimate of human worth, be forbidden, when injurious, under the penalty of at least making reparation for all the injury of which it had been the cause.

Offences of the Press with respect to Government.

We have now explained, we trust, with sufficient clearness for the present occasion, the principles upon which laws should be constructed for protecting the rights of individuals against violations committed by the press. The first part of this inquiry, therefore, we must consider as completed. In the second part we have to explain the principles upon which they should be constructed for protecting the operations of government.

This question involves a point which presents the appearance of considerable difficulty. In the first place, unless a door is left open to resistance of the government, in the largest sense of the word, the doctrine of passive obedience is adopted; and the consequence is, the universal prevalence of misgovernment, with the misery and degradation of the people. In the second place, unless the operations of government, instituted for the protection of rights, are secured from obstruction, the security of rights, and all the advantages dependent upon the existence of government, are at an end. Between these two securities, both necessary to obtain the benefits of good government, there appears to be such a contrariety, that the one can only be obtained by the sacrifice of the other.

As this difficulty, however, arises chiefly from the largeness of the terms, a close inspection of the cases which they involve, and which they have a tendency to confuse, will enable us to discover the course which it belongs to practical wisdom to pursue.

It is necessary, first of all, to ascertain what sort of obstructions are inconsistent and what are not inconsistent, with the operations of government, which are necessary for the protection of rights.

The application of physical force to resist the government in applying, to the execution of the laws, the physical power placed at its disposal by the law, is such an obstruction of the operations of government as would, if frequent, render it inadequate to the ends which it is provided to secure. This application of force, therefore, must be treated as an offence; and any thing proceeding from the press, tending directly to produce it, as a similar offence.

This proposition requires to be illustrated. The application of physical force which is here described, and treated as an evil, is clearly distinguishable from that resistance of government which is the last security of the many against the misconduct of the few. This is an application of physical force to obstruct the operations of government in detail; the proceedings, for example, of a court of justice, the proceedings of the legislative organ, or the proceedings of any of the administrative functionaries, in the execution of the duties with which they are charged. This is not that species of resistance which is necessary in the last resort to secure the people against the abuse of the powers of government. This last is not a resistance to the operations of government in detail. It is a resistance to all

Liberty of the Press. the powers of government at once, either to withdraw them from the hands in which they have hitherto been deposited, or greatly to modify the terms upon which they are held.

Even this last species of resistance it may be necessary to punish, at least in a certain degree, whenever it is not successful; that society may not be disturbed by frequent commotions, in the motives to which, the majority of the people do not partake. This, however, is a question which belongs to the penal code in general, and does not concern the inquiry into the offences capable of being committed by the press: because we think it may be satisfactorily shown, that no operation of the press, however directly exhorting to this species of resistance, ought to be treated as an offence. The reason is, that no such exhortation can have any immediate or formidable effect; can, indeed, have any effect at all, except through such mediums as ought to be at all times perfectly free. Suppose that a work is published, exhorting the people in general to take arms against the government, for the purpose of altering it against the consent of its rulers. The people cannot take arms against the government without the certainty of being immediately crushed, unless there has been already created a general consent. If this consent exists in such perfection as to want nothing to begin action but an exhortation, nothing can prevent the exhortation, and forbidding it is useless. If the consent does not exist in nearly the last degree of perfection, a mere exhortation, read in print, can have no effect which is worth regarding. In all circumstances, therefore, it is useless, and consequently absurd, to treat this species of exhortation as an offence. If, on the other hand, it were clearly recognized, that every man had a licence to exhort the people to the general resistance of the government, all such exhortations would become ridiculous, unless on those rare and extreme occasions in which no prohibitions and no penalties can or ought to prevent them. The doctrine of this paragraph, which will appear somewhat startling and paradoxical to minds accustomed only to a certain train of ideas, will receive illustration and we trust will be amply confirmed as we proceed.

Having mentioned this as a grand exception, we now return to the cases in which not only physical force applied to obstruct the operations of government, but the publishing of exhortations to that obstruction, ought to be treated as an offence. These relate solely, as above remarked, to the operations of government in detail. Obstructions, it is evident, may be offered to the operations in detail of a government which possesses and deserves the fullest confidence of the community at large, and the press may be employed in directly and efficiently exciting to these obstructions. A hand-bill, for example, may be distributed in a morning, which, operating upon an inflamed state of mind, in a narrow district, may excite a mob to disturb the proceedings of a court of justice, to obstruct the officers of law, police, or government, in the execution of their duties, or to disturb, on this or that occasion, the deliberations of the legislature itself.

These are clearly hurtful acts; they may be very

Liberty of
the Press.

accurately defined; and penalties, of moderate severity, would be sufficient to deter from the performance of them. The obligation of the offending party to make satisfaction to the party injured, would often, in offences of this description, be excluded, because there would be no definite party to whom an injury would be occasioned. It would only be necessary to ascertain the sorts of motives by which such offences would be liable to be produced, and to apply skilfully, as in other cases, motives of an opposite tendency, sufficient to counteract them. This would not be more difficult in this than in other cases, and it is not, therefore, necessary to explain at any length the mode of performing it. One principle is to be carefully and most religiously observed, that of not imposing an atom of punishment for the purposes of *vengeance*. This is a principle, the justness and importance of which are so completely recognized, that we might have expected to be relieved ere now from the necessity of recommending attention to it. The fact, however, is, that so long as there are abuses in governments, so long will the men who have the means of profiting by those abuses, exert themselves to multiply the list of offences against government, and to apply to them punishments of the greatest severity. Punishments for contempt of court; punishments to vindicate the honour of the court, of the government, of the magistracy; punishments for the support of dignity; punishments severe in proportion as the dignity of the party offended is supposed to be high, and so on, are punishments almost always applied for purposes of vengeance, or the protection of the instruments of abuse. They are punishments, therefore, which will be rigidly excluded from a code which wisely and steadily pursues the general good.

What the *sort of acts* are, to which the exhortations of the press ought not to be applied, has been so far ascertained. The next point is, to determine with accuracy what *sort of exhortation* it is that ought to be forbidden. To all those who profit by the abuses of government, that is, more especially to all those who, in a defective government, wield any of its powers, it is of great importance to leave, as undefined as possible, the sort of exhortation that ought to be forbidden. The point of greatest importance to them is, to keep the people at large from complaining, or from knowing or thinking that they have any thing of which to complain. If this grand object is fully attained, they may then, without anxiety, and without trouble, riot in the pleasures of misrule. There is no limit to the degree in which the few may pursue their own advantage at the expense of the many. There can be nothing, therefore, in which they have a greater interest, than preventing the press from being employed in any such way, as will lead the people to think that they have any thing, on the part of their rulers, of which to complain. All artifices possible will be sure to be employed to effect that prevention. And if it is enacted, that exhortations to acts which obstruct the operations of government in detail should be punished, *without defining accurately what sort of exhorta-*

tions, they will easily find expedients which, to a great extent, will accomplish their purpose.

Liberty of
the Press

Under the sort of constructions which it will be their interest to apply, every thing which can be done by the press, to make the people know or believe that there is any thing in the system of their government, or the conduct of their rulers, of which they have to complain, may be treated as an exhortation to obstruct the operations of government. Of these constructions, our experience affords innumerable examples. Does not the imputing of defects to the government, or misconduct to those who wield the powers of government, tend to bring both "into hatred and contempt?" And if the people hate and condemn the institutions and rulers of their country, will they not oppose their operations? The imputing of these faults, therefore, is it not, in essence and effect, an exhortation to oppose the operations of government? And are we to be governed, in our legislature, by the mere forms in which a set of words may appear, and not by our knowledge of their nature and consequences?

This is not only exceedingly plausible, but almost all the propositions which it involves are perfectly true. It is thus, therefore, the more easy to establish such a mode of interpreting an indefinite law of the press, as will prevent, or where the people cannot yet bear a total prevention, will go far towards preventing whatever can lead the people to believe that any thing is amiss in the manner in which they are ruled.

There are two species of exhortations, one the explicit and direct, the other implied and constructive. In the one, a particular act is pointed out, and the party, or parties, addressed are called upon to perform it. In the other, certain grounds only are laid, from which the opinion of the addresser may be inferred, more or less certainly, that the act ought to be performed.

With respect to the first, there is no occasion for doubt. A direct and explicit exhortation to commit one of those acts described above, as obstructing the operations of government in detail, should be treated as an offence. The precise question is, whether any exhortation, which is only implied and constructive, should be considered an offence? In the answer to this question, almost every thing which relates to the use of the press in matters of government, will be found to be involved.

We have already divided the subject of resistance to government into two parts; first, that general resistance, the object of which is, some great change in the government at large; and, secondly, resistance to this or that of its operations in detail.

We have already adduced an argument, which appears to us to be conclusive, to show, that no exhortation, whether explicit or implied, direct or indirect, the object or tendency of which is to produce the first species of resistance, ought to be subject to legal restraint.

It is necessary here to enter a little more fully into the grounds of that opinion.

We think it will appear, with sufficient evidence, that in the way of indirect exhortation to resistance,

Liberty of
the Press.

that is, in laying the grounds of dissatisfaction with the government, there is no medium between allowing every thing and allowing nothing; that the end, in short, which is sought to be gained, by allowing any thing to be published in censure of the government cannot be obtained, without leaving it perfectly free to publish every thing.

The end which is sought to be obtained by allowing any thing to be said in censure of the government, is to ensure the goodness of the government, the most important of all the objects, to the attainment of which, the wisdom of man can be applied. If the goodness of government could be ensured by any preferable means, it is evident that all censure of the government ought to be prohibited. All discontent with the government is only good, in so far as it is a means of removing *real cause* of discontent. If there is no cause, or if there is better means of removing the cause, the discontent is, of course, an evil, and that which produces it an evil.

So true it is, however, that the discontent of the people is the only means of removing the defects of vicious governments, that the freedom of the press, the main instrument of creating discontent, is, in all civilized countries, among all but the advocates of misgovernment, regarded as an indispensable security, and the greatest safeguard of the interests of mankind.

For what is meant by a vicious government? or wherein do the defects of government consist? Most assuredly they all consist in sacrificing the interests of the many to the interests of the few. The small number, in whose hands the powers of government are in part directly, in part indirectly placed, cannot fail, like other men, to have a greater regard for what is advantageous to themselves, than what is advantageous to other men. They pursue, therefore, their own advantage, in preference to that of the rest of the community. That is enough. Where there is nothing to check that propensity, all the evils of misgovernment, that is, in one word, the worst evils by which human nature is cursed, are the inevitable consequence. (See the article GOVERNMENT.)

There can be no adequate check without the freedom of the press. The evidence of this is irresistible. In all countries, the people either have a power legally and peaceably of removing their governors, or they have not that power. If they have not that power, they can only obtain very considerable ameliorations of their governments by resistance, by applying physical force to their rulers, or, at least, by threats so likely to be followed by performance, as may frighten their rulers into compliance. But resistance, to have this effect, must be general. To be general, it must spring from a general conformity of opinion, and a general knowledge of that conformity. How is this effect to be produced, but by some means, fully enjoyed by the people, of communicating their sentiments to one another? Unless where the people can all meet in general assembly, there is no other means known to the world of attaining this object to be compared with the freedom of the press.

It is, no doubt, true, that in countries where the

Liberty of
the Press.

liberty of the press is unknown, evil governments are frequently overthrown. This is almost always accomplished by the military force, revenging some grievance of their own, or falling in with some heat and animosity of the people. But does it ever enable them to make a new government, in which any greater security is provided for their interests than there was before? In such cases, the people get rid of one set of rulers, whom they hate, only to obtain another set, with equal powers of doing them injury.

There are, however, we believe, some people who say, that though the liberty of the press is a necessary instrument to attain good government, yet, if it is fairly attained, and if legal and peaceable means are in the hands of the people of removing their governors for misconduct;—if the people of England, for example, really chose the members of the House of Commons, and renewed their choice so frequently as to have the power of removal after a short experience of misconduct, the freedom of the press would be unnecessary.

So far is this from being true, that it is doubtful whether a power in the people of choosing their own rulers, without the liberty of the press, would be an advantage.

It is perfectly clear, that all chance of advantage to the people from having the choice of their rulers, depends upon their making a good choice. If they make a bad choice—if they elect people either incapable, or disinclined, to use well the power entrusted to them, they incur the same evils to which they are doomed when they are deprived of the due control over those by whom their affairs are administered.

We may then ask, if there are any possible means by which the people can make a good choice, but the *liberty of the press*? The very foundation of a good choice is knowledge. The fuller and more perfect the knowledge, the better the chance, where all sinister interest is absent, of a good choice. How can the people receive the most perfect knowledge relative to the characters of those who present themselves to their choice, but by information conveyed freely, and without reserve, from one to another?

There is another use of the freedom of the press, no less deserving the most profound attention, that of making known the conduct of the individuals who have been chosen. This latter service is of so much importance, that upon it the whole value of the former depends.

This is capable of being rigidly demonstrated. No benefit is obtained by making choice of a man who is well qualified to serve the people, and also well inclined to serve them, if you place him in a situation in which he will have motives sufficient to serve himself at their expence.

If any set of men are chosen to wield the powers of government, while the people have not the means of knowing in what manner they discharge their duties, they will have the means of serving themselves at the expence of the people; and all the miseries of evil government are the certain consequences.

Suppose the people to choose the members of the Legislative Assembly, with power of rechoosing, or dismissing, at short intervals: To what desirable end

Liberty of
the Press.

could these powers be exercised, without the liberty of the press? Suppose that any one of those whom they have chosen has misconducted himself, or promoted, as far as depended upon him, the ends of misgovernment, how are the people to know that the powers with which they had entrusted him had been treacherously employed?

If they do not know, they will rechoose him, and that as cordially as the man who has served them with the greatest fidelity. This they are under a deplorable necessity of doing, even to be just; for, as they know no difference between him and the best, it would be on their part iniquity to make any. The consequences would be fatal. If one man saw that he might promote misrule for his own advantage, so would another; so, of course, would they all. In these circumstances, we see laid the foundation on which, in every country, bad government is reared. On this foundation it is impossible that it should not be reared. When the causes are the same, who can expect that the effects will be different? It is unnecessary to dwell upon these fundamental truths, because they have already been developed in the article **GOVERNMENT**.

Without the knowledge, then, of what is done by their representatives, in the use of the powers entrusted to them, the people cannot profit by the power of choosing them, and the advantages of good government are unavailable. It will surely not cost many words to satisfy all classes of readers that, without the free and unrestrained use of the press, the requisite knowledge cannot be obtained.

That an accurate report of what is done by each of the representatives, a transcript of his speeches, and a statement of his propositions and votes, is necessary to be laid before the people, to enable them to judge of his conduct, nobody, we presume, will deny. This requires the use of the cheapest means of communication, and, we add, the free use of those means. Unless every man has the liberty of publishing the proceedings of the Legislative Assembly, the people can have no security that they are fairly published. If it is in the power of their rulers to permit one person, and forbid another, the people may be sure that a false report,—a report calculated to make them believe that they are well governed, when they are ill governed, will be often presented to them.

One thing more is necessary, and so necessary, that, if it is wanting, the other might as well be wanting also. The publication of the proceedings tells what is done. This, however, is useless, unless a correct judgment is passed upon what is done.

We have now brought the inquiry to this important point: In the article **GOVERNMENT**, we have seen that, unless the people hold in their own hands an effectual power of control on the acts of their government, the government will be inevitably vicious. We have now seen, that they cannot exercise this control to any beneficial purpose without the means of forming a correct judgment upon the conduct of their representatives. We have likewise seen, that one of the means necessary to enable them to judge correctly of the conduct of their representatives, is the liberty to every body of publishing reports of

what they do. It remains to inquire, by what other acts the press can be made to contribute to the same desirable end.

What is wanted is, that all the people, or as many of them as possible, should estimate correctly the consequences of the acts proposed or done by their representatives, and also that they should know what acts might have been proposed, if the best were not proposed, from which better consequences would have followed. This end would be accomplished most effectually, if those who are sufficiently enlightened would point out to those who are in danger of mistakes, the true conclusions; and showing the weight of evidence to be in their favour, obtain for them the universal assent.

How is this to be accomplished? In what manner are those wise men to be chosen? And who are to be the choosers? Surely it is evident the object cannot be attained. There are no distinct and indubitable marks by which wisdom, and less by which integrity, is to be known. And who is to be trusted with the privilege of pointing them out? They whose judgment requires to be directed are not well qualified to determine who shall direct them. And if the rulers are to choose, they will employ those only who will act in uniformity to their views, and enable them to benefit themselves by the pillage and oppression of the people.

As there is no possible organ of choice, no choice whatever ought to be made. If no choice is to be made, every man that pleases ought to be allowed. All this is indubitable. The consequences of denying any part of it are so obvious, that hardly any man, we suppose, will risk the imputations to which such a denial would justly expose him.

They who say that no choice ought to be made, say, in effect, that no limit whatsoever ought to be imposed upon the liberty of the press. The one of these propositions is involved in the other. To impose any restraint upon the liberty of the press undoubtedly is to make a choice. If the restraint is imposed by the government, it is the government that chooses the directors of the public mind. If any government chooses the directors of the public mind, the government is despotic.

Suppose that, by the restraint imposed upon the liberty of the press, all censure of the government is forbidden, here is undoubtedly a choice. The government, in this case, verbally says, the people who might attempt the task of directing the public mind are of two sorts; one that of those who would censure, another that of those who would not censure: I choose the latter.

Suppose that not every censure, but only such and such kinds of censure, are forbidden, here, again, is still a choice, while confessedly there is no party to whom the power of choosing for the rest can with safety be given.

If not every censure, but only some censures, are to be forbidden, what are those to which the prohibition should extend? The answer to this question will elucidate nearly all that yet remains in any degree obscure, of the doctrine of the liberty of the press.

It will not be said that any censure which is just

Liberty of
the Press.

Liberty of
the Press.

should be forbidden; because that would undoubtedly be to detract from the means of enabling the people to form correct judgments; and we have, we trust, rendered it indisputable that no source of benefit to society is at all to be compared with that of correct judgments on their government and its functionaries, formed among the people, and determining their actions.

But what censures are just and what are unjust; in other words, what are the conclusions which ought to be formed respecting the properties and the acts of the government, is exactly the point to be determined. If you say that no man is to pass an unjust censure upon the government, who is to judge? It is surely unnecessary to repeat the proof of the proposition, that there is nobody who can safely be permitted to judge. The path of practical wisdom is as clear as day. All censures must be permitted equally, just and unjust.

Where various conclusions are formed among a number of men, upon a subject on which it would be unsafe, and therefore improper, to give to any minor portion of them a power of determining for the rest, only one expedient remains. Fortunately, that is an expedient, the operation of which is powerful, and its effects beneficial in the highest degree. All the conclusions which have formed themselves in the minds of different individuals, should be openly adduced; and the power of comparison and choice should be granted to all. Where there is no motive to attach a man to error, it is natural to him to embrace the truth; especially if pains are taken to adapt the explanation to his capacity. Every man, possessed of reason, is accustomed to weigh evidence, and to be guided and determined by its preponderance. When various conclusions are with their evidence presented with equal care and with equal skill, there is a moral certainty, though some few may be misguided, that the greater number will judge aright, and that the greatest force of evidence, wherever it is, will produce the greatest impression.

As this is a proposition upon which every thing depends, it is happy that the evidence of it should be so very clear and striking. There is, indeed, hardly any law of human nature more generally recognized, wherever there is not a motive to deny its existence. "To the position of Tully, that if Virtue could be seen, she must be loved, may be added," says Dr Johnson, "that if Truth could be heard, she must be obeyed." (*Rambler*, No. 87.)—"Je vous plains, mes Peres," says Mons. Pascal to the Jesuits, "d'avoir recours à de tels remèdes. Vous croyez avoir la force et l'impunité: mais je crois avoir la vérité, et l'innocence. C'est une étrange et longue guerre que celle où la violence essaie d'opprimer la vérité. Tous les efforts de la violence ne peuvent affaiblir la vérité, et ne servent qu'à la relever davantage: toutes les lumières de la vérité ne peuvent rien pour arrêter la violence, et ne font que l'irriter encore plus. Quand la force combat la force, la plus puissante détruit la moindre: quand l'on expose les discours aux discours, ceux qui sont véritables et convainquants confondent et dissipent ceux qui n'ont que la vanité et le men-

songe." (*Lett. Provinc.* 12.)—"Reason," says Burke, "clearly and manfully delivered, has in itself a mighty force; but reason, in the mouth of legal authority, is, I may fairly say, irresistible." (*Lett. on Regicide Peace*.)

It is of importance to show how many of the greatest men, of all ages and countries, have borne testimony to the prevalence of true over false conclusions, when both are fairly offered to the human mind. "Truth," says Mr Locke, "certainly would do well enough, if she were once left to shift for herself. She seldom has received, and I fear never will receive, much assistance from the power of great men, to whom she is but rarely known, and more rarely welcome. She is not taught by laws, nor has she any need of force to procure her entrance into the minds of men." (*Letter on Toleration*.) The following is the emphatical language of Montesquieu: "La raison a un empire naturel; elle a même un empire tyrannique: on lui résiste, mais cette résistance est son triomphe, encore un peu de temps, et l'on sera forcé de revenir à elle." (*Esp. de Loix*, l. 28, ch. 38.)—"It is noted out of Cicero, by Machiavel, that the people, though they are not so prone to find out truth of themselves, as to follow custom, or run into error; yet if they be shown truth, they not only acknowledge and embrace it very suddenly, but are the most constant and faithful guardians and conservators of it." (*Harrington*.)—"The labour of a confutation," says Chillingworth, "I have not in any place found such labour or difficulty, but that it was undertakeable by a man of very mean abilities; and the reason is, because it is Truth I plead for; which is so strong an argument for itself, that it needs only light to discover it." (*Religion of Protestants*.)—"About things on which the public thinks long," says Dr Johnson, "it commonly attains to think right." (*Life of Addison*.)—"The adversary," says Dr Campbell, "is both subtle and powerful. With such an adversary, I should on very unequal terms enter the lists, had I not the advantage of being on the side of truth. And an eminent advantage this doubtless is. It requires but moderate abilities to speak in defence of a good cause. A good cause demands but a distinct exposition, and a fair hearing; and we may say, with great propriety, it will speak for itself." (*Campbell on Miracles*. Introd.)

We have then arrived at the following important conclusions,—that there is no safety to the people in allowing any body to choose opinions for them; that there are no marks by which it can be decided beforehand, what opinions are true and what are false; that there must, therefore, be equal freedom of declaring all opinions, both true and false; and that, when all opinions, true and false, are equally declared, the assent of the greater number, when their interests are not opposed to them, may always be expected to be given to the true. These principles, the foundation of which appears to be impregnable, suffice for the speedy determination of every practical question.

All censure thrown upon the government, all censure thrown either upon the institutions of the government, or upon the conduct of any of the func-

Liberty of
the Press.

Liberty of
the Press.

tionaries of government, supreme or subordinate, has a tendency to produce resistance to the government. Of the censures thrown upon government, some may have a tendency to produce resistance to the operations of government in detail; others to produce that general resistance which has in view some great alteration in the government.

Of the first sort would be any such accusation of the conduct and disposition of a judge, as might excite the people, whose sympathies were roused in favour of the individual against whom his sentence was to operate, to rescue him from the officers of justice. We have already shown that such a rescue ought to be punished, and any direct exhortation to it ought to be punished. It will now be evident, we trust, that no censure on the judge, though capable of being treated as an indirect exhortation, ought to be punished.

The reason is conclusive. The people ought to know, if possible, the real qualities of the actions of those who are entrusted with any share in the management of their affairs. This they have no chance of knowing, without the unlimited power of censure upon those actions, both in gross and detail. To see the full force of these propositions, it is only necessary to apply the principles which have been already established.

If the people have not the means of knowing the actions of all public functionaries, they have no security for the good conduct even of their representatives. Suppose it is the duty of their representatives to watch the conduct of the judges, and secure the perfection of judicature, the people cannot know whether their representatives perform their duty, unless they know what the conduct of the judges is. Ignorance of this would of itself suffice to vitiate the government. A door would be left open, through which the rulers might benefit themselves at the expense of the people. All the profit to be made by an abuse of the power of justice, would thus become the profit of the representatives, by whom it would be allowed, and encouraged as far as the knowledge, which they could not withhold from the people, would permit.

That the people ought, therefore, to know the conduct of their judges, and when we say judges we mean every other functionary, and the more perfectly the better, may be laid down as indubitable. They are deprived of all trust-worthy means of knowing if any limit whatsoever is placed to the power of censure.

All censure consists in the delivery of an unfavourable opinion, with or without the grounds of it. This is the essence of censure. But if the conduct of the judge deserves that an unfavourable opinion should be entertained of it, the more perfectly that is known to the people the better.

The conduct of the judge, on this occasion, says a defender, does not deserve an unfavourable opinion: A public expression of such an opinion ought, therefore, to be prohibited. But the conduct of some judge, on some occasion, deserves an unfavourable opinion. When it is deserved, there is no security for good government, unless it is allowed to be made known. How can you allow an unfavourable opinion

to be delivered in the one case, and not delivered in the other? To have the benefit of it in the one case, you must submit to the evil of it in the other.

Liberty of
the Press.

As the real point of importance is, to establish correct opinions in the minds of the people, it is as mischievous to inculcate a favourable opinion, when an unfavourable is deserved, as an unfavourable when a favourable is deserved; and, in the eye of reason, it is incontrovertible, that, if the one deserves to be prevented by punishment, so does the other. But, if an unfavourable opinion is pronounced of any public functionary; of a judge, for example, would you have it left uncontradicted? Would you not grant the liberty of calling in question the truth of the allegations, and of supporting a different opinion? In that case, it is abundantly evident, that the character of no public functionary would be safe, and that any man, however deserving, might be made to appear the proper object of the most unfavourable sentiments.

It is perfectly certain, that it is not in the power of law to mark out, by antecedent definition, any sort of men, of whom it can say, all opinions favourable to such men shall be punished. It can never be affirmed of any men beforehand that they will certainly perform such and such injurious actions. If they do perform them, all declarations conformable with the matter of fact are good. But the question is, whether they have performed them? One man affirms that they have. Is that to be taken for granted? And is no man to be allowed to affirm the contrary, and to sift the grounds upon which the allegations of the other man are supported? It is by weighing well the evidence on both sides, that a well-founded opinion is capable of being formed. This is perfectly certain. It is equally certain, that the best security for having the evidence on both sides fully adduced, and the strength and weakness of it perfectly disclosed, is by permitting all those who are attached to different opinions to do what they can for the support of their own.

If it is evident that it ought not to be permitted to speak evil of public functionaries without limit, while any limit is put to the power of speaking well of them; it is equally evident that, for the purpose of forming a correct opinion of their conduct, it ought not to be permitted to speak well of them, and oppose any limit whatsoever to the power of speaking ill of them. It ought not to be permitted to speak evil of them without an equal liberty of speaking well; because, in that case, the evidence against them might be made to appear much stronger than it was. It ought not to be permitted to speak well of them without an equal liberty of speaking ill; because, in that case, the evidence in favour of them might be made to appear much greater than it really was. In either case, the people would be misguided, and defrauded of that moral knowledge of the conduct of their rulers, the paramount importance of which has so fully appeared.

It may be said (as by the short-sighted, if we did not anticipate them, it would be said), that if, by limiting the power of censure, the people are made to judge more favourably of their rulers than they deserve, the evil is small; but if they are permitted to

Liberty of
the Press.

form a very unfavourable opinion, the consequences are alarming.

We believe it may be rigidly demonstrated, that no evils are greater than those which result from a more favourable opinion of their rulers, on the part of the people, than their rulers deserve; because just as far as that undue favour extends, bad government is secured. By an opinion of their rulers more favourable than they deserve, is implied an ignorance on the part of the people of certain acts of their rulers by which the people suffer. All acts by which the rulers have any motive to make the people suffer, are acts by which the rulers profit. When the ignorance of the people extends to material points, all the evils of bad government are secured. These are the greatest of all possible evils. To this it will not be said that the ignorance of the people ought to extend. On all material points, it is admitted, then, that the freedom of censure ought to be complete. But if it is to be allowed on great points, on those where it is calculated to exact the greatest disapprobation, what can be thought of their consistency who would restrain it on those where it is only calculated to excite a small? If it is proper to protect the people from great injuries at the hands of their rulers, by exciting a strong, it is good to protect them against small injuries by exciting a weak disapprobation.

To public functionaries may be imputed either acts which they have not performed, or a want of certain qualifications, moral or intellectual, which they do possess.

With respect to acts, and even dispositions, which do not, either directly or indirectly, concern their public function, the same protection may be safely extended to them as to private men.

Acts in their public capacity which they have not performed, may be imputed to them either by mere forgery, and without any appearance of ground, or they may be imputed with some appearance of ground. From permitting the former, no good can be derived. They ought, therefore, to be prevented, in the same way as false imputations, injurious to individuals in their private capacity. That there should be no restraint in imputing actions to any public functionary which he may appear to have done, flows immediately from the principles already established, and requires not that any thing should here be added to its proof. Any appearance sufficient to lay the foundation of the slightest suspicion, renders it useful to call the attention of the public to the suspected part, which can only be done by making the suspicion known. A man may, indeed, publish, as a matter of fact, what is supported by appearances which would only justify the slightest suspicion. In that case, he is sure of incurring the disgrace of temerity, if not of malignity; and this is all the penalty which needs or can safely be inflicted upon him.

In imputing inaptitude to a public functionary, on the score either of intellectual or moral qualities, scarcely any limitation would be safe. Every man ought to have liberty to declare upon this subject any opinion which he pleases, and support it by any evidence which he may think adapted to the end. If, in supporting his opinion of the inaptitude of any

Liberty of
the Press.

public functionary, he imputes to him actions which there is not even an appearance of his having performed, that limited prohibition, the propriety of which we have just recognised, will strictly apply. With this exception, freedom should be unimpaired.

We have now, therefore, explained, we hope sufficiently, in what manner the principles which we have established require that the use of the press should be regulated in speaking of the action of public functionaries, and their fitness for the duties which they are appointed to discharge; whether those functionaries are the immediate representatives of the people, or others whom it is the business of their representatives to control.

We have next to inquire in what manner those principles require that the use of the press should be regulated in speaking of the institutions of government. The illustrations already adduced will supersede the use of many words upon this part of the subject.

Institutions of government are good in proportion as they save the people from evil, whether it be evil created by the government, or not prevented by the government. Institutions of government are bad in proportion as they are the cause of evil to the people, either by what they create, or fail in preventing.

According to this statement, which it is impossible to controvert, institutions of government may, in strict propriety of speech, be said to be the cause of all the evil which they do not save the people from, and which any other institutions would save them from.

It is therefore of the highest importance that the people should know what are the institutions which save them from the greatest quantity of evil, and how much their own institutions want of being conformable to those best institutions.

Institutions of government are bad, either because those in whose hands the powers of government are placed do not know that they are bad, and though willing, cannot improve them; or they are bad, because those who have in their hands the powers of government do not wish that they should be improved.

Where the rulers are willing, but do not know how to improve, every thing which leads to a knowledge of these defects is desirable to both rulers and people. That which most certainly leads to such knowledge is, that every man who thinks he understands any thing of the subject, should produce his opinions, with the evidence on which they are supported, and that every man who disapproves of these opinions should state his objections. All the knowledge which all the individuals in the society possess upon the subject is thus brought, as it were, to a common stock or treasury, while every thing which has the appearance of being knowledge, but is only a counterfeit of knowledge, is assayed and rejected. Every subject has the best chance of becoming thoroughly understood, when, by the delivery of all opinions, it is presented in all points of view; when all the evidence upon both sides of every question is brought forward, and all those who are most interested in showing the weakness of what is weak in it, and the

Liberty of
the Press.

strength of what is strong, are, by the freedom of the press, permitted, and by the warmth of discussion excited, to devote to it the keenest application of their faculties. False opinions will then be delivered. True; but when are we most secure against the influence of false opinions? Most assuredly when the grounds of these opinions are the most thoroughly searched. When are the grounds of opinions most thoroughly searched? When discussion upon the subject is the most general and the most intense; where the greatest number of qualified persons engage in the discussion, and are excited by all the warmth of competition, and all the interest of important consequences, to study the subject with the deepest attention. To give a body of rulers, or any other body of men, a power of choosing for the rest opinions upon government without discussion, we have already seen, upon good evidence, is the way to secure the prevalence of the most destructive errors.

When institutions are bad, and the rulers would gladly change them if they knew they were bad, discussion, it will not be disputed, would be good for both parties, both rulers and ruled. There is, however, another case, and that by far the most common, where the rulers are attached to the bad institutions, and are disposed to do all in their power to prevent any alteration. This is the case with all institutions which leave it in the power of them who are entrusted with the powers of government, to make use of them for their own advantage, to the detriment of the people; in other words, which enable them to do injury to the people, or prevent the people from good. This is the case with by far the greater number of those institutions by which the people suffer. They are institutions contrived for benefiting the few at the cost of the many.

With respect, therefore, to the greater number of defective institutions, it is the interest of the rulers that true opinions should not prevail. But with respect to these institutions, it is of still greater importance to the people that discussion should be free. Such institutions as the rulers would improve, if they knew that they were defective, will be improved as the rulers themselves become sensible of their defects. Such defective institutions as the rulers would not wish to see improved, will never be improved, unless the knowledge of these defects is diffused among the people, and excites among them a disapprobation which the rulers do not think it prudent to disregard.

That the prevalence of true opinions among the people, relative to those defects in their political institutions, by which the rulers profit at their expence, is of the utmost importance to the people, is therefore a proposition which no improbity will dare openly to controvert. That freedom of discussion is the only security which the people can have for the prevalence of true opinions, has already been proved. It is therefore proved that freedom of discussion, in its utmost perfection, they ought to enjoy.

What is included in the term *freedom of discussion*, is evident from what has already been said.

Freedom of discussion means the power of representing all opinions, equally, relative to the subject of

Liberty of
the Press.

discussion; and of recommending them by any medium of persuasion which the author may think proper to employ. If any obstruction is given to the delivering of one sort of opinion, not given to the delivering of another; if any advantage is attached to the delivery of one sort of opinion, not attached to the delivery of another, so far equality of treatment is destroyed, and so far the freedom of discussion is infringed;—so far truth is not left to the support of her own evidence, and so far, if the advantages are attached to the side of error, truth is deprived of her chance of prevailing.

To attach advantage to the delivering of one set of opinions, disadvantages to the delivering of another, is to make a choice. But we have already seen, that it is not safe for the people to let any body choose opinions for them. If it be said, that the people themselves might be the authors of this preference, what is this but to say, that the people can choose better before discussion than after; before they have obtained information than after it? No, if the people choose before discussion, before information, they cannot choose for themselves. They must follow blindly the impulse of certain individuals, who, therefore, choose for them. This is, therefore, a pretence, for the purpose of disguising the truth, and cheating the people of that choice, upon which all their security for good government depends.

If these deductions are as clear and incontrovertible as to us they appear to be, the inquiry respecting the principles which ought to regulate the use of the press is drawn pretty nearly to its close. We have shown, that as far as regards the violation of the rights of individuals in respect to both persons and things, no definition on account of the press is required. We have shown in what manner the rights of individuals, in regard to reputation, should be defined by the civil code, and the violation of them prevented by the penal. We next proceeded to what may be considered as the main branch of the inquiry, namely, the use of the press in speaking of the institutions and functionaries of government. We have found, that in this respect the freedom of the press is of such importance, that there is no security for good government without it. We have also found, that the use of it, in respect to these subjects, admits but of two useful restrictions;—that of a direct exhortation to obstruct any of the operations of government in detail, and that of imputing to a functionary of government a criminal act, which there was no ground, nor even any appearance of ground, to impute to him. These restrictions, of course, it would be very easy to define in the criminal code, and to find appropriate motives to sanction. In all other respects, we have seen that the press ought to be free; that if there is any limit to the power of delivering unfavourable opinions, either of the functionaries or the institutions of government, and of recommending those opinions by any media, with the single exception of false facts, under the circumstances mentioned above, the benefits which may be derived from the freedom of the press are so greatly infringed, that hardly any security for good government can remain.

In the administration of English law, or rather of

Liberty of
the Press.

what is called law, upon this subject, without being any thing better than the arbitrary will of the judges, it is said, that though discussion should be free, it should be "decent;" and that all "indecent" in discussion should be punished as a libel. It is our object in this discourse to give an exposition of the manifold deformities of the English law of libel. If we have been successful in developing the true principles which ought to regulate the freedom of the press, every reader may, by an application of those principles, determine what he ought to think of the several particulars which may there attract his attention. We shall confine ourselves to a short notice of those *dicta*, or doctrines, which seem most likely to be pleaded in opposition to the principles which we have endeavoured to establish.

The question is, whether *indecent* discussion should be prohibited? To answer this question, we must, of course, inquire what is meant by indecent. In English libel law, where this term holds so distinguished a place,—is it not defined? English legislators have not hitherto been good at defining; and English lawyers have always vehemently condemned, and grossly abused it. The word "indecent," therefore, has always been a term under which it was not difficult, on each occasion, for the judge to include whatever he did not like. "Decent," and "what the judge likes," have, therefore, been pretty nearly synonymous.

Indecency of discussion cannot mean the delivery either of true or of false opinions, because discussion implies both. In all discussion there is supposed at least two parties, one who affirms and one who denies. One of them must be in the wrong.

The delivery, then, of all true opinions, yet of some may be said to be indecent. All opinions are either favourable or unfavourable. True opinions may be favourable to government and its functionaries, or may not be said to be indecent, nor will all opinions that are true and unfavourable be marked out for prohibition under that name. Opinions unfavourable may either be greatly unfavourable or slightly unfavourable. If any unfavourable opinions are exempted from the charge of indecency, it must be those which are slightly so. But observe, what would be the consequence of prohibiting, as indecent, those which are greatly unfavourable. A true opinion, greatly unfavourable to a functionary, or institution of government, is an opinion that the functionary, or institution, is greatly hurtful to the people. You would permit the slight evil to be spoken of, and hence removed; you would not permit the great evil to be spoken of.

If no true opinion can be regarded as indecent, meaning by indecent, requiring *punishment*, we must inquire if any false opinion on matters of government ought to be treated as such. If all false opinions are indecent, all discussion is indecent. All false opinions, therefore, are not indecent. The English libel law does not treat any favourable opinions how much soever false, as indecent. If all opinions that are false and unfavourable are said to be indecent, who is to judge if they are false? It has been already proved, that the people can confide the power of determining what opinions are true, what are false, to

Liberty of
the Press.

none but themselves. Nothing can resist this argument. Either the people do know, or they do not know, that an opinion is false. If they do not know, they can permit nobody to judge for them, and must leave discussion its free course. If they do know, all infliction of evil for the delivery of an opinion which then can do no harm, would be purely mischievous and utterly absurd.

If all opinions, true and false, must be allowed to be delivered, so must all the *media* of proof. We need not examine minutely the truth of this deduction, because it will probably be allowed. It will be said, however, that though all opinions may be delivered, and the grounds of them stated, it must be done in calm and gentle language. Vehement expressions, all words and phrases calculated to inflame, may justly be regarded as indecent, because they have a tendency rather to pervert than rectify the judgment.

To examine this proposition, it must be taken out of that state of vagueness in which so many things are left by the English law, and made, if possible, to speak a language, the meaning of which may be precisely ascertained.

We have just decided, as appeared, on very substantial grounds, that the statement of no opinion, favourable or unfavourable, true or false, with its media of proof, ought to be forbidden. No language, necessary for that purpose, can be indecent, meaning here, as before, nothing by that term, as nothing can be meant, but simply *punishable*, or proper for punishment.

But the only difference between delivering an opinion one way and another way is, that in the one case it is simply delivered, in the other it is delivered with indications of passion. The meaning of the phrase in question then must be, that an opinion must not be delivered with indications of passion. What! not even a favourable one? "Oh, yes! a favourable one. Merited *praise* ought to be delivered with warmth." Here, then, is inequality, and therefore mischief at once. An opinion, meaning here a true opinion, if it is favourable, you allow—if unfavourable, you do not allow—to be delivered in a certain way. Why? Because in that way, you say, it is calculated to make an undue impression. Opinions favourable, then, you wish to make an undue impression, and by that confess the wickedness of your intention. You desire that the people should think better of the institutions and functionaries of their government than they deserve; in other words, you wish the government to be bad.

If opinions, to what degree soever unfavourable, may be freely and fully delivered, there are two conclusive reasons why the terms in which they are delivered should not be liable to punishment. In the first place, the difference between one mode of delivery and another is of little consequence. In the second place, you cannot forbid the delivery in one set of terms, without giving a power of preventing it in almost all.

1. *The difference is of little consequence.* If I say barely that such a functionary of government, or such an institution of government, is the cause of great injury and suffering to the people, all that I

Liberty of
the Press.

can do more by any language is, to give intimation, that the conduct of such functionary, or the existence of such institution, excites in me great contempt, or great anger, or great hatred, and ought to excite them in others. But if I put this in the way of a direct proposition, I may do so, because then it will be a naked statement with regard to a matter of fact, and cannot be forbidden, without overthrowing the whole of the doctrine which we have already established. If, then, I give indication of certain sentiments of mine, and of my opinion of what ought to be the sentiments of others *explicitly*, I ought, you say, to be held innocent; if *implicitly*, guilty. Implicitly, or explicitly, that is the difference, and the whole of the difference. If I say, that such a judge, on such an occasion, took a bribe, and pronounced an unjust decision, which ruined a meritorious man and his family, this is a simple declaration of opinion, and ought not, according to the doctrine already established, to meet with the smallest obstruction. If I also state the matter of fact with regard to myself, that this action has excited in me great compassion for the injured family, and great anger and hatred against the author of their wrongs, this must be fully allowed. I must further be allowed to express freely my opinion, that this action ought to excite similar sentiments in other members of the community, and that the judge ought to receive an appropriate punishment. Much of all this, however, I may say in another manner. I may say it much more shortly by implication.—Here, I may cry, is an act for the indignation of mankind! Here is a villain, who, invested with the most sacred of trusts, has prostituted it to the vilest of purposes! Why is he not an object of public execration? Why are not the vials of wrath already poured forth upon his odious head?—All this means nothing, but that he has committed the act; that I hate him for it, and commiserate the sufferers; that I think he ought to be punished; and that other people should feel as I do. It cannot be pretended, that between these two modes of expression the difference, in point of real and ultimate effect, can be considerable. For a momentary warmth, the passionate language may have considerable power. The permanent opinion formed of the character of the man, as well as the punishment which, under a tolerable administration of law, he can sustain, must depend wholly upon the real state of the facts; any peculiarity in the language in which they may have been originally announced soon loses its effects. If that language has expressed no more indignation than what was really due, it has done nothing more than what the knowledge of the facts themselves would have done. If it has expressed more indignation than what was due, the knowledge of the facts operates immediately to extinguish it, and, what is more, to excite an unfavourable opinion of him who had thus displayed his intemperance. No evil then is produced; or none but what is very slight and momentary. If there should be a short-lived excess of unfavourable feeling, we have next to consider what is the proper remedy. Punishment should never be applied, when the end can be attained by more desirable means. To destroy any excess of unfavourable feeling, all that is necessary is, to show

the precise state of the facts, and the real amount of the evil which they import. All excess of feeling arises from imputing to the facts a greater efficacy in the way of evil than belongs to them. Correct this opinion, and the remedy is complete.

Liberty of
the Press.

2. *You cannot forbid the use of passionate language, without giving a power of obstructing the use of censorial language altogether.* The reason exists in the very nature of language. You cannot speak of moral acts in language which does not imply approbation and disapprobation. All such language may be termed passionate language. How can you point out a line when passionate language begins, dispassionate ends? The effect of words upon the mind depends upon the association which we have with them. But no two men have the same associations with the same words. A word which may excite trains of emotion in one breast, will excite none in another. A word may appear to one man a passionate word, which does not appear so to another. Suppose the legislature were to say, that all censure, conveyed in passionate language, shall be punished, hardly could the vices either of the functionaries or institutions of government be spoken of in any language which the judges might not condemn as passionate language, and which they would not have an interest, in league with other functionaries, to prohibit by their condemnation. The evil, therefore, which must of necessity be incurred by a power to punish language to which the name of *passionate* could be applied, would be immense. The evil which is incurred by leaving it exempt from punishment is too insignificant to allow that almost any thing should be risked for preventing it.

Religion, in some of its shapes, has, in most countries, been placed on the footing of an institution of the state. Ought the freedom of the press to be its complete, in regard to this, as we have seen that it ought to be, in regard to all other institutions of the state? If any one says that it ought not, it is incumbent upon him to show wherein the principles which are applicable to the other institutions fail in their application to this.

We have seen, that, in regard to all other institutions, it is unsafe for the people to permit any but themselves to choose opinions for them. Nothing can be more certain, than that it is unsafe for them to permit any but themselves to choose for them in religion. If they part with the power of choosing their own religious opinions, they part with every power. It is well known with what ease religious opinions can be made to embrace every thing upon which the unlimited power of rulers, and the utmost degradation of the people, depend. The doctrine of *passive obedience* and non-resistance was a *religious doctrine*. Permit any man, or any set of men, to say what shall and what shall not be religious opinions, you make them despotic immediately. This is so obvious, that it requires neither illustration nor proof.

But if the people here, too, must choose opinions for themselves, discussion must have its free course; and the same propositions which we have proved to be true in regard to other institutions, are true in regard to this.

Limerick.
 Situation
 and Extent.

LIFE PRESERVERS. See PRESERVERS.
LIMERICK, a county in Ireland, in the province of Munster, is bounded by the river Shannon, which separates it from Clare on the north; by Tipperary on the east; on the south by Cork; and on the south-west and west by Kerry. Its greatest extent, from east to west, is about 51 miles, and from north to south 32; and its area is about 1045 English square miles, or 688,800 English acres; which is divided into nine baronies, besides the liberties of the towns of Limerick and Killmalloch, and 126 parishes.

Surface. &c.

This is, in general, a low lying fertile district, surrounded by high grounds on the south-east, south, and west, from which the country has a gentle declivity towards the Shannon. The mountains on the south-east, called the Galtees, extend into Tipperary; and, on another range, very steep but less elevated, on the west, is the boundary with Kerry. On the banks of the Shannon there is a tract of low grounds, extending to more than 100,000 acres, chiefly alluvial, and of the richest quality. Besides the Shannon, this county is watered by several considerable streams. Of these the largest is the Maig, which has its source in the mountains on the south-east, and flowing through it from south to north, falls into the Shannon below Limerick. The Gale, and the Feale, which pass into Kerry, rise in the western mountains, and also the Blackwater, which flows eastward through the county of Cork on the south. The principal lake is Lough Gur, about five miles in circumference, in which there are three small islands. At the city of Limerick, rain falls for about two-thirds of the year; the barometer ranges between 28 and 30.5, and the thermometer between 28° and 74°. A great number of villas near this city, the summer residence of its wealthy merchants; several gentlemen's seats in different parts of the county, and some venerable ruins, both religious and military, give variety to a landscape which is not remarkable for its natural scenery.

Much of the county is divided among a few great proprietors, whose rentals are from £2000 to £40,000 a-year. The land seems to be of greater yearly value than in most parts of Britain at a distance from large towns; for, according to Mr Wakefield's information, the green acres would have let, in 1808, for three guineas the Irish acre, or almost 40s. the English. Considerable farms brought five guineas the Irish acre, and in some instances more. The rent of the mountain-land had increased in a still greater proportion than the grazing and corn farms. One grazier held land of the value of £10,000 a-year, and in one season, slaughtered, in Cork, 600 head of cattle. Many of the best long-horned cattle of the united kingdom are fattened here, and also a considerable number of sheep. Two year old wethers sold then, without their fleeces, at from £2, 10s. to £3. Only a small proportion of the land is in tillage. The produce of this, and some of the adjacent counties, in proportion to the seed, is stated by the same author to be at a medium,—of wheat 10, bear 17, barley 12, oats 9, and potatoes 10. Hemp was formerly cultivated extensively on the rich low grounds, called the *Caucasses*, on the banks of the

Shannon, but this tract is now occupied in grazing. Flax of an excellent quality, for sailcloth, is still grown in several parts. The common term of leases is 31 years and three lives.

The towns and principal villages are, Limerick, Askeaton, Newcastle, Abbey-Feale, Adair, Killmalloch, Bruff, and Castle Connell. The last is a fine village, much resorted to for its mineral springs. Limerick is the only considerable town; and, next to Dublin and Cork, it is the most populous and commercial town in Ireland. Though situated on the Shannon, 60 miles from the sea, vessels of 300 tons come up close to the Custom-house: and it has a communication with Dublin by the Grand Canal. A large share of the provision and corn trade of Ireland is, accordingly, possessed by this city. In 1810, Limerick exported 50,998 barrels of wheat, 173,793 of oats, and 74,680 of barley, the value of the whole being little short of £300,000. It is said to contain about 60,000 inhabitants. See LIMERICK, in the *Encyclopædia*.

In 1811, the wages of common labour throughout the county were, of men, the year round, 1s. 2d. a day, and of women, 9d.; in hay and corn harvest, 1s. 10½d. Potatoes were 3½d. per stone; beef and mutton, 6d. and 6½d. per pound; wheat, per barrel of 20 stones, 39s.; and oatmeal, 16s. 6d. the cwt.

Two members are returned to Parliament for the county, in which there are more than 3000 freeholders, and one for the city of Limerick. According to Mr Wakefield, two individuals have influence enough to return the member for the city and one of the county members. A colony of Palatines was established here more than a century ago, who still form a distinct race of industrious small farmers. The far greater part of the inhabitants are Catholics. These held much of the leasehold and personal property, but few large estates. Of the militia for the city of Limerick, consisting of 600 men, only seven of the privates were Protestants, at the time when Mr Wakefield wrote, and all the privates of the county militia were Catholics, excepting 50. Not a twelfth of the inhabitants of the city were Protestants. The population, in 1790, according to Mr Beaufort, was 170,000; it has been lately computed at 250,000.—See the general works referred to under the former Irish counties.

(A.)

LINCOLNSHIRE, an English maritime county. It is bounded on the north by Yorkshire, on the east by the German Ocean and Norfolk, on the south by Cambridge, Northampton, and Rutland shires, and on the west by Nottinghamshire and Leicestershire. Its greatest length is 73 miles, and its greatest breadth 48. The area is 281½ square miles, or about 1,800,000 acres.

The county is divided into three districts or provinces. The largest of these, Lindsey, is more extensive than the other two, containing more than 1,000,000 acres, and stretching from the shores of the German Ocean to Nottinghamshire. It is rather an elevated tract of country, but the whole so level as scarcely to contain a single hill. The north-eastern part of this division is a very extensive district of heathy land, generally very poor, especially the northern part of it, and denominated the Wolds.

Extent and Boundaries.

Divisions.

Lincoln-
shire.

Though some parts of it have recently been brought into cultivation, yet a great portion has scarcely any other live stock than the numerous rabbits, which multiply in extended warrens. A small part, however, of this division, contains a rich track of low land, formed by the rivers Trent, Dun, and Idle, where horned cattle are pastured, and some excellent flax is produced. The province of Lindsey is subdivided into fifteen hundreds and two sokes.

The province of Kesteven extends along the western side of the county, from its middle to its southern extremity; on which latter part is a portion of the fens. Notwithstanding there are many extensive heaths, especially near Lincoln and Ancaster, and though the soil and elevation is various, yet, on the whole, it may be properly described as a fertile country. Towards the west, a ridge of hills, which forms an abrupt boundary, extends from Grantham nearly to Lincoln; but none of the points attain a great elevation. This province is subdivided into nine hundreds and three sokes.

The third province, Holland, contains the greater part of that unhealthy division of Lincolnshire usually called the *Fens*. It is subdivided into three hundreds, sometimes denominated Sokes, sometimes Wapentakes. The character of this province is similar to the province of the same name in the Netherlands, after which it has been called. Nearly the whole of it appears, at a remote period, to have been covered by the sea, and only brought to its present state of productiveness by the active and persevering labour of the inhabitants. The embankments and the draining have been expensive, perpetual, and progressive, and the soil that has been redeemed has conferred a most abundant remuneration. Excellent pasture land has been formed out of the swamps and bogs, and some of it produces extraordinary crops of corn, especially oats. Even in those parts that have not been reclaimed, the reeds, which abound, are converted into good covering for houses and barns, and they are well stocked with aquatic wild fowl. The taking of them is a profitable employment to many persons, and the markets of London are principally supplied from thence with those delicacies. The decoys in this district are more numerous than in any other part of England. They are commonly formed around quiet pools, to which pipes made of bent willows, and covered with nets, gradually enlarging as they approach the water, are conducted. Into the large orifice of the pipes, the wild birds are enticed by tame ones trained for that business, and who conduct them into the funnel, when the appearance of a man or his dog behind, drives them to the most contracted part, where they are taken. The quantity of birds taken in some seasons is prodigious, amounting to some hundreds of thousands. They usually consist of teal, widgeon, and wild ducks, but occasionally wild geese, godwits, snots, ruffs, and reeves and whimbrels are caught. In these otherwise unproductive fens, the keeping of geese, principally for the sake of the feathers, is a considerable branch of rural industry, and supplies a large part of the demands of the kingdom, both for beds and for pens.

Wild Fowl.

Lincoln-
shire.

The feathers are plucked from the birds at three, four, sometimes five different periods in the course of a year. This is thought to be a barbarous custom, but the charge is denied by the breeders, who assert, that, for their own profit, they pluck only those feathers which are so near falling off as to occasion little pain; those more firmly fixed, and which have some portion of blood at their end, being of very inferior value. The young ones are plucked as well as the old ones; experience having taught that, when plucked early, the future growth of the feathers becomes greater. During the breeding season, the birds are lodged in the same houses as their owners, in wicker pens, which are arranged in rows, frequently in the bed-chambers. A gooseherd in attendance on the flock leads them daily to water, and assists them, on their return, to get into their several cells. The attendants are acquainted with each individual goose in the flock, and can commonly distinguish them by the tones of their voices. Near Spalding, there is a considerable heronry, and a smaller one near Surfleet, where the herons, like rooks, build their nests on high trees.

The air in the fens is generally insalubrious, and the inhabitants suffer much from the nature of the water, which is generally of a brackish quality; and though they make reservoirs to preserve rain water, in dry summers, they experience very great distress. In warm weather, vast swarms of insects add to the annoyances of this district.

By the returns of 1811, the inhabitants of Lincolnshire were 237,891, viz. 117,022 males, and 120,869 females. In the preceding year the baptisms were 3963 males, 3857 females; the deaths 2736 males, and 2784 females. The houses were 47,467, which were inhabited by 50,904 families: of these 29,881 were chiefly employed in agriculture, 13,184 in trade, and 7889 in neither.

The towns containing more than 2000 inhabitants are the following:

	Houses.	Inhabitant
Lincoln (city),	1839	8861
Boston,	1837	8180
Gainsborough,	1227	5172
Lowth,	1035	4728
Stamford,	820	4582
Spalding,	944	4330
Grantham,	683	3646
Holbeach,	617	2962
Great Grimsby,	668	2747
Horncastle,	571	2622
Barton,	486	2204

The towns whose population is betwixt 1000 and 2000 are Sleaford, Crowland, Bourn, Swineshead, Donnington, Epworth, Crowle, Brigg, Alford, Wainfleet, Kirton-in-Lindsey, and Caistor.

Lincolnshire returns twelve members to the House of Commons, viz. two for the county, two for the city of Lincoln, and two for each of the boroughs of Boston, Grantham, Great Grimsby, and Stamford. The titles derived from places in this county are, of *Barons*, Brownlow, Bolingbroke, Boston, Holland, Grantham, Harrowby, Irnham (Irish); of *Earls*, Lincoln, Lindsey, Stamford, Yarborough, and Digby.

Lincoln-
shire.

The capital of this county is the see of a Bishop, whose jurisdiction is the largest of any in England, extending over the counties of Lincoln, Leicester, Huntingdon, Bedford, and Buckingham; over one half of Hertfordshire, and several portions of Oxfordshire, Berkshire, Rutlandshire, Northamptonshire, and Warwickshire; and including 1517 parishes under the superintendence of six archdeacons.

Rivers, Ca-
nals, and
Dikes

The fens of Lincolnshire have through them wide ditches, which serve to drain the water from the land, and which, when united and extended, become navigable, and highly beneficial as means of conveying the productions to the various markets. The Foss Dike, the earliest canal made in Britain, was constructed in the year 1121, to form a connection between the city of Lincoln and the river Trent; and though, from the nature of the soil, it has been often obstructed, and the expence of keeping it in order has been great, it has continued to be used from that time to the present day. The river Trent, though rising in Staffordshire, may be considered as a Lincolnshire river, from the principal navigation upon it belonging to this county. It receives the Dun and the Ouse, and, before reaching the sea, unites with the Humber. It is navigable for large barges to Gainsborough. It has, on the influx of the tide, a most extraordinary bore, or, as it is provincially termed, *eager*, when the waters run up resembling a wall with a rapidity that has no equal in any of our English rivers, except the Wye at Chipstow. The Witham rises within the county, about ten miles from Stamford. The early part of its course is through a beautiful district till it reaches the fen country, when its course becomes sluggish; but being navigable to Boston, is highly beneficial both for draining and for commerce. The other rivers are the Ancholme, the Welland, the Glen, the Grant, and the Ouse. The Humber, indeed, is its boundary on part of the northern side, but is more commonly and properly considered as a Yorkshire than a Lincolnshire river, from Hull, its principal port, being in that county. Two small canals communicate with the river Witham, one from Horncastle, the other from Sleaford.

The great bay or estuary into which the different rivers and dikes that drain the fens are disembogued, is very shallow, and filled with drifting sands, that make the approach to the shore highly dangerous. The rivers are constantly loaded with mud, and, in times of flood, encounter the tide, equally charged with its floating silt, which causes a stagnation and deposit that is constantly shifting its position, as the strength of the rivers or of the tides happen to be the most powerful.

Face of the
country

The face of the country in the fens is generally uninteresting, exhibiting extensive plains, with nothing to break the continuity of the line of vision, and only rendered less monotonous by the vast numbers of cattle with which the green meadows are covered. On the wolds a more bleak and dreary prospect presents itself, but the western division of the country, near Stamford and Grantham, is variegated, woody, and undulating, and presents generally pleasing pictures.

Agriculture

The agriculture of the fens is of the simplest

kind; for where nature has created such a productive soil, little remains to be done by the operations of man. In the more elevated parts of the county the cultivation is conducted with various, but, on the whole, good judgment; and the land produces ample crops of wheat, oats, barley, and beans, and, in some parts, hemp and flax. The attention, however, of the whole county is more turned to derive profit from cattle than from the use of the plough.

Lincoln-
shire.

The oxen of Lincolnshire are proverbial for their goodness. The original race were of a great size, with large heads and short horns, thick in the bone, deep in the belly, short on the neck, high on the rump, and bare on the shoulders; but these have been improved by such various and judicious crossings of breeds, that their symmetry and excellent qualities render them the best in the island. Many cattle bred in other countries are fattened here on the rich natural pastures, but a portion of oil-cake is very commonly given, to fit them earlier for the market of Smithfield, to which numerous droves are weekly dispatched. This fattening of cattle for the supply of London is so advantageous, that the dairy is almost everywhere considered as a secondary object.

Oxen

The sheep of this county are almost peculiar to it. They are of a large size, have horns, and produce heavy fleeces of long wool, highly prized in the manufacture of stuffs and some kinds of baizes. The flesh is, however, rank in flavour, and, unless the animals are improved by crossing with other races, is not generally relished. As the foundation of an excellent breed, they were selected by the late judicious Mr Bakewell, who, from mixing them with other races, produced those excellent sheep known by the name of the "new Leicesters." The fleeces of the pure Lincolnshire sheep in general weigh from ten to twelve pounds, but extraordinary instances have been known in which they have attained more than twenty pounds.

Sheep

The live stock, in which this county exceeds every other, is rabbits, which the numerous warrens on the wolds produce in vast numbers. From their prodigious quantity the flesh is of small value, and the sale of the skins for the use of the furriers and hatters is the principal source of profit. The number of warrens has considerably diminished of late years, and the land they occupied appropriated to tillage; but they are still very extensive.

Rabbits

Lincolnshire is not a manufacturing county: before the extension of machinery, the spinning of their native wool gave occupation to the female part of the population, but that employment has been nearly discontinued of late years, and no other has yet been substituted in its place. In some parts the flax is spun for domestic use. The nature of its sea-shores operate to prevent foreign commerce, and there is little or no intercourse between Lincolnshire and the ports even of Holland and Germany, that are opposite to it. The county produces neither minerals nor coals.

Trade and
Manu-
factures

The antiquities of Lincolnshire are numerous. Almost all the churches are fine specimens of ancient architecture, a singularity which distinguishes them from those in every other county of England. The

Antiquities.

shire.

remains of Crowland, founded in 716, the seat of a Mitred Abbot, and anciently a place of great fame, are still visited by every antiquary; and near them, is the triangular bridge over three streams, in good preservation. It is, however, so lofty and precipitous, that it is only useful to horse and foot travellers, as carriages usually pass under it. The other most prominent antiquities are Torksey Castle, at the junction of the Foss Dike with the Trent; Thornton Abbey, near the Humber; Bardney Abbey, on the banks of the Witham; Tattershall Castle, on the same river; and Somerton Castle, in the parish of Boothby.

Sir Isaac Newton, Lord Burleigh, Lord Bolingbroke, Stukeley the Antiquarian, and Wesley, the founder of Methodism, were, among many other eminent men, natives of this county.

The most remarkable seats of noblemen and gentlemen are, Blankney, Charles Chaplin, Esq.; Brocklesby Park, Lord Yarborough; Coleby Hall, Earl Lindsey; Gauthy, Robert Vener, Esq.; Grinsthorpe Castle, Lord Gwydir; Hanby Hall, Sir Wm. Manners; Harmston, Sam. Thorold, Esq.; Hainton Park, G. Heneage, Esq.; Nocton Park, Earl of Buckinghamshire; Belton House, Lord Brownlow; Normanby Hall, Sir J. Sheffield; Reevesby Abbey, late Sir Joseph Banks; Subton, Sir Robert Heron; Summer Castle, Lady Wrey; Syston, Sir John Thorold; Thurgunby, Lord Middleton.

See Young's *General Agricultural View of Lincolnshire*; Brayley and Britton's *Beauties of England and Wales*; and Stone's *Agricultural Survey*.

(w. w.)

LINLITHGOWSHIRE, or **WEST-LOTHIAN**, a county in Scotland, having the Frith of Forth on the north, Edinburghshire, or Mid-Lothian, on the east and south-east, Lanarkshire on the south-west, and Stirlingshire on the west, is situated between 55° 49' and 56° 1' north latitude, and 3° 18' and 3° 51' west longitude from Greenwich. It is of a triangular form, about 19 miles long on its eastern boundary, and 13 on its western; but at a medium it is only about 7 miles broad and 16 long, according to the *Agricultural Survey*, and its area is therefore 112 square miles, or 71,680 English acres.

So large a portion of the surface of this county is either level, or gently undulating, that only a fifth part of it is stated to be unfit for cultivation. Yet a considerable space is occupied by hills. A ridge extends across it from north-west to south-east, of which Cairnpapple, the most elevated point, is about 1500 feet high. The highest ground is in the middle, and towards the west; on the south there is much moor and moss; but the hills for the most part yield good pasturage, and some of them are planted. The climate, though variable, is not severe. The prevailing winds are from the west, which blow for about two-thirds of the year. According to a register of the weather, kept at Duddington on the coast of the Frith, about the middle of the northern boundary, the greatest number of rainy and snowy days, in any one year, for a period of thirty years, from 1778 to 1808, was 111 (in 1780), and the smallest number 22 (in 1803); but days on which slight showers fell are not included. The greatest heat in

that period was in June 1785, when the thermometer stood at 87° in the shade, in a northern exposure. In June 1787, there was a week of frost, with ice one-sixteenth of an inch thick.

Though there is a great variety of soil in this district, and considerable tracts of gravel and sand, yet clay is the most general. The better kinds of clay extend over a fourth of the area; but the inferior sorts, incumbent on a close bottom, are still more extensive.

The only streams of any note are the Almond, which rises on the border of Lanarkshire, and flows north-east for about 24 miles between this county and Edinburghshire; and the Avon, which forms the western boundary for about 12 miles. Both these rivulets fall into the Frith of Forth. On the north side of the town of Linlithgow, there is a lake about a mile long, and half a mile broad, which contains pike, perch, and eels; and a smaller one on the south, stocked with the same kind of fish. In the parishes of Linlithgow, Ecclesmachan, and Abercorn, are several sulphureous springs, and a strong chalybeate is found in the parish of Torphichen; but none of them are much resorted to.

Silver and lead were at one time got in the hills of Bathgate, in the parish of Linlithgow, and in the neighbourhood a small vein of silver ore was found several years ago in a limestone quarry. Ironstone is wrought occasionally in the parishes of Borrowstounness and Carriden. Sandstone, in some places of an excellent quality, prevails along the coast of the Forth, and also in the interior; and there is an inexhaustible store of limestone. But the chief mineral production is coal, which abounds in almost every part of it, and is wrought in the parishes of Borrowstounness and Carriden on the Forth, in Uphall and Whitburn on the east and south, and in the parish of Bathgate in the middle. An excellent kind of coal has been wrought within these few years near Cultmuir, on the south-western border. The Union Canal, which passes through this county, will afford the means of transporting the coal of the interior to the city of Edinburgh. (See **EDINBURGHSHIRE** in this Supplement.)

Linlithgowshire is for the most part divided into estates worth from L.200 to L.3000 a-year; but there are a few above, and several below these extremes. In the neighbourhood of the burghs of Linlithgow and Queensferry there are properties of only a few acres. Four of the greatest estates, rented at from L.4000 to L.10,000, belong to as many noblemen. In 1806, the number of freeholders, entitled to vote in the election of a member for the county, was 67. The valued rent, taken in 1649, is L.75,027, 12s. 2d. Scots; in 1806, the real rent was L.64,518, 18s. 7d. Sterling; and, in 1811, the real rent of the lands and mines was L.82,947, 2s., and of the houses L.5,798, 8s. Almost half the county is entailed. The principal seats are Hopetoun House, Earl of Hopetoun, two miles west of Queensferry; Barnbougle Castle and Livingston House, Earl of Rosebery; Craigiehall, Mr Hope Vere; Duddington, Mr Dundas; Hallyards, Mr Ramsay; Houston, Mr Sharp; Kinneil, Duke of Hamilton, near Borrowstounness; and Polkemmet, Mr Baillic.

Linlithgow-
shire.
Farms.

The size of farms is from 50 Scots acres to 600, but the greater part are between 100 and 300 English acres. The rent of the better soils, which extend over half the county, varies from L.2 to more than L.5 the acre; that of the inferior clays is from 14s. to 20s., and of the high grounds from 6d. to 10d.; the average rent of the whole, in 1811, being rather more than 23s. the English acre. The common term of leases is 19 or 21 years; but, in some instances, they are for 24, 38, and even 57 years; grazing farms are let on short leases, from one to four years. The crops raised are the same as in the other counties in this quarter of Scotland, which have been already described; and the general system of husbandry is not materially different, except that the dairy is more an object here than in the counties to the east and south-east.

The towns are Linlithgow, Borrowstounness, and Queensferry; and the principal villages are Whitburn and Bathgate. Linlithgow, the county town, and a royal burgh, sixteen miles west from Edinburgh, contained, in 1811, 2557 inhabitants. It was formerly a place of considerable trade, but is now in a decaying state. The manufactures of the town and parish are paper, leather, stockings, malt, and spirituous liquors, calico printing and tambouring. The standard dry measures of Scotland were committed to the charge of this burgh, and still bear its name. These are the firiot of 2199 cubic inches for wheat, rye, beans, peas, meal, and salt; and another of 3208 cubic inches for malt, barley, and oats. The Palace, situated on an eminence overlooking the lake on the north side of the town, was founded by Edward I. of England. The Regent Murray was assassinated on the streets of this town, by Hamilton of Bothwellhaugh, on 22d January 1569. Borrowstounness is a port on the Frith of Forth, eighteen miles west from Edinburgh, containing about 2200 inhabitants, who are partly employed in shipbuilding, and in the manufacture of salt, earthenware, and soap.

Queensferry, a royal burgh, is nine miles west from Edinburgh. The width of the Frith of Forth here is only two miles, with convenient landing-places on either side. (See QUEENSFERRY in the *Encyclopædia*.) In the middle of the Frith at this place is the small island of Inchgarvie, surmounted by a ruinous fort. The village of Bathgate is eighteen miles west, and Whitburn twenty-one south-west from Edinburgh. Borrowstounness is the only place which carries on some external commerce, but its trade has declined since the Forth and Clyde Canal was opened. The chief exports are coal, salt, and soap, and the imports timber, hemp, flax, &c. The herring fishery in the Frith is prosecuted with various success; the usual season is from November to February. There is also a salmon fishery on some parts of the coast, particularly between Queensferry and Blackness.

Linlithgowshire sends one member to Parliament; and, in the elections for the burghs, the town of Linlithgow unites with Selkirk, Peebles, and Lanark; and Queensferry with Stirling, Culross, Inverkeithing, and Dunfermline. It is divided into twelve entire parishes, and contains portions of other three, the rest of which belong to the county of Edinburgh. With the exception of the parish of Cramond, of which only a small part is situated in Linlithgowshire, all these parishes belong to the Presbytery of Linlithgow, in the Synod of Lothian and Tweeddale. The poor are relieved for the most part by the rents of land and interest of money, the donations of individuals, and from the ordinary funds of the kirk-sessions; but in some parishes poor-rates are raised by assessment. The annexed tables contain an abstract of the census of 1800 and 1811.

LITHOGRAPHY,

Litho-
graphy.

THE art of taking impressions from drawings or writings made on stone.

The principles on which this art is founded are, 1st, The quality which a compact granular limestone has of imbibing grease or moisture; and, 2dly, The decided antipathy of grease and water for each other.

A drawing being made on the stone with an ink or crayon of a greasy composition, is washed over with water, which sinks into all the parts of the stone not defended by the drawing. A cylindrical roller, charged with printing-ink, is then passed all over the stone, and the drawing receives the ink, while the water defends the other parts of the stone from it on account of its greasy nature.

This process, therefore, depends entirely on chemical principles, and is thus distinct from letter-press or copper-plate printing, which are altogether mechanical. On this account it has in Germany been called *chemical printing*; and, as metallic plates can be prepared to be printed from in a similar manner, Lithography is considered only as a branch of chemical printing.

I. HISTORY OF LITHOGRAPHY.

History
of Art

The invention of Lithography was the result of accident. Its inventor, Alois Senefelder, the son of a performer at the Theatre-Royal of Munich, was placed for education in the University of Ingoldstadt, as a student of jurisprudence; but, after his father's death, he attempted a theatrical career. Not succeeding in this, he became an author, though his poverty prevented him from publishing his works. He now tried many plans with copper-plates and compositions, as substitutes for letter-press, in order to be his own printer. He found, in the course of his experiments, that a composition of soap, wax, and lamp-black, formed a good material for writing on his plates; that, when dry, it became firm and solid, and that it resisted aquafortis. Wanting facility in writing backwards on the plates, he got some pieces of Kilheim stone, as cheap materials, on which he could practise after polishing their surfaces. One day being desired by his mother to take an account of some linen about to be sent to be washed, and having no paper at hand, he wrote the account on a polished stone, with his composition ink, intending to copy it at his leisure. When he was afterwards about to efface this writing, it occurred to him that he might obtain impressions from it; and, having eaten away the stone with acid for about the hundredth of an inch, he found that he could charge the lines with printing-ink, and take successive impressions. This new mode of printing appeared to him very important, and he persevered through all difficulties in applying his discovery to practical purposes, and in improving it.

In the course of many experiments, he found that it was not necessary to have the letters raised above

the surface of the stone, but that the chemical principles by which grease and water are kept from uniting, were alone sufficient for his purpose. This point obtained, Lithography may be said to have been fully discovered. All that was required was the improvement of the materials, and the mode of working with them, and the construction of a proper press for taking the impressions.

The perseverance with which he followed up his experiments, in order to overcome the difficulties which successively arose in his progress, is astonishing, and the more so, considering the total want of method in his proceedings. Often has he wasted months in surmounting a difficulty which a little knowledge, or a very little reasoning, would have enabled him to conquer immediately. His uniform plan seems to have been, to try the first thing that came to hand, and so on in succession, till chance rewarded his assiduity by presenting to him the material suited to his purpose.

The first essays to print for publication were some pieces of music, executed in 1796; afterwards he attempted drawings and writings. The difficulty he had in writing backwards led him to the process of *transfer*, and the use of dry soap, which was found to leave permanent traces, which would give impressions, naturally led to the mode of chalk drawings.

Having made considerable improvements, Mr Senefelder obtained, in 1799, a patent privilege for Bavaria, when he made known his process, and afterwards entered into partnership with Mr André, of Offenbach, who proposed to establish presses, and take out patents at London, Paris, and Vienna. For this purpose Senefelder came to London with a brother of André's, and the invention having been much spoken of, under the name of *Polyautography*, most of the principal English artists made trials of it. Unfortunately, however, the art of printing from the stones was not then fully understood, and the difference between the materials of Germany and those of England, used both for the purposes of drawing and printing, caused constant failures, and the artists in succession abandoned the practice of it. To this cause is to be attributed the unpopularity of Lithography till recently in England, as it was left entirely in the hands of *amateurs*, whose productions, generally speaking, did no credit to the art, and whose faults were in some degree supposed to be those of the art itself.

In August 1800, Senefelder, who had now separated from André, went to Vienna, where, after much difficulty, a patent was obtained, and extensive preparations were made, for applying his process to print cottons; but bad management and some unfortunate circumstances, prevented his success, and he returned to Munich in 1806, leaving the establishment in other hands.

Mr Mitterer, Professor of Drawing at the Public School at Munich, now (1806) practised Lithography

Litho-
graphy

Litho-
graphy.

to multiply copies for the pupils, and is said to have invented the chalk composition in its present form, or at least to have improved it greatly.

From this period the practice of the art has extended and improved rapidly, and more particularly at Munich, where several establishments were formed, for the purpose of applying it to the fine arts, as well as for printing writings and official forms, for the different departments of the government.

In October 1809, Senefelder was appointed Inspector of the Royal Lithographic Establishment at Munich, for printing from stone a complete map and survey of Bavaria; since which period he has devoted his time to experiments, and to writing the history of his invention. Among other points of improvement to which his attention has been directed, is a substitute for the stones, which are inconvenient to use on account of their weight, and they are also liable to break in the press, when used without due caution, or when they contain flaws. For this purpose he has made a composition of drying oil, finely ground earth, and other substances, which is thinly spread over pieces of parchment; but it has not hitherto been found to answer. The surface cracks after repeated wetting and exposure to the power of the press, and the printing-ink is then taken in the cracks, and spoils the impressions. Thus a very small number only of good impressions can be obtained. A public exhibition of printing from this stone paper was made in London, on the 23d July 1821, by a partner of Mr Senefelder; but the result was not such as to induce much confidence in the ultimate success of the trials to form this desirable substitute of a light material for a heavy one.

In England Lithography can scarcely be said to have been entirely given up since its first introduction in 1800, although it was but little practised or thought of after 1805, till its revival at the latter end of 1817; since then it has been more generally attended to, and some of the establishments having now become well acquainted with the process of printing, specimens have been produced in England equal to those of any other country.

In France but little was done in lithography till 1815, when it was established at Paris by Lasteyrie, and being taken up by good artists, it soon attained great excellence. About the same time it extended to Russia and other parts of Europe.

II. DESCRIPTION OF THE MATERIALS, AND THE MODE OF PREPARING THEM.

1. *Of the Stones, and the manner in which they are prepared to receive the Drawings.*

Stones

As calcareous stones will all imbibe grease and moisture, and effervesce with an acid (the use of which will appear when we speak of the process of printing), they are all capable of being used for Lithography. Those are best adapted to the purpose which are very compact, of a fine and equal grain, and free from veins, or imbedded fossils or crystals.

The quarries of Solenhofen, near Pappenheim in Bavaria, furnished the first plates, and none have as yet been found to equal them in quality. They are of a very uniform pale yellowish white colour. The

fracture is perfectly conchoidal. The beds divide into thin portions of considerable size, with perfectly flat surfaces, and were on this account carried to Munich and other places for paving kitchens and halls, and thus came in the way of Senefelder, when he discovered the chemical process of printing.

The stones of this quarry vary in their quality, but the best are in great abundance. Generally speaking, the hardest are the best, provided they are quite uniform in texture. Such are necessary for fine chalk drawings, softer ones may do for ink, or for coarser drawings in chalk.

In France, stones have been found near Chateauroux (*Département de l'Indre*), of a similar colour to those of Solenhofen, and even harder and of a finer grain, but they are so full of large spots of a softer nature, that it is scarcely possible to get one perfect of a greater size than twelve inches square.

In England a stone has been used for Lithography which is found at Corston near Bath. It is one of the white lias beds, but not so fine in grain or so close in texture as the German stone, and therefore far inferior. But it is good for transfers, and does tolerably well for ink drawings or writings. Another stone, found near Stony Stratford, is also used; but it is of a brownish grey tint, and too dark in colour to show the effect of the drawing with sufficient clearness.

To bear the pressure used in taking the impressions, a stone twelve inches square should be at least one inch and a quarter thick. The thickness must increase with the size of the stone, but two inches and a half are a thickness sufficient for stones of three feet by three feet and a half.

The stones, when sawn to a proper size and thickness, are ground level by rubbing two of them face to face with water and sand, and very carefully examined with a straight-edge, to ascertain that they are perfectly level in all directions. This applies only to the side which is afterwards to receive the drawing, as the natural division of the stone is sufficiently true for the back.

To prepare them for chalk drawings, two stones, which have been perfectly levelled, are well washed in order to free them from any of the coarser grains or sand which have been previously used upon them. They are now to be placed on a board over a trough, and a small quantity of water and very fine sand being strewed over the surfaces, they are to be rubbed face to face, adding occasionally a little fresh sand and water. The best sort of sand in England is that called silver sand, for preparing the stone, and the common brown sand for giving a fine grain. The sands must be passed through a sieve of the fineness required, which will vary with the nature of the drawing; and the greatest care must be taken to have the sieves perfect, and to prevent any coarser particles of sand from being mixed with the rest. A single grain would fill the stone with innumerable scratches, which would all appear in the drawing. The upper stone is in this operation moved in small circles, carefully and equally all over the under one, taking care not to move the one beyond the edge of the other, or the faces would become rounded. When the grain is equal, and sufficiently fine, the stones are carefully

Litho-
graphy.

Litho-
graphy.

washed, and wiped with a clean cloth. The stone, thus prepared, should have, when dry, a perfectly uniform appearance in the colour and grain, and resemble a sheet of vellum. It should be free from scratches, and have no shining parts. The upper stone is always the finer grained of the two.

Sometimes dry sand alone is used, but it is better to use it with water.

To prepare the stones for ink drawings or writings, the process just described is first followed; they are then well washed to get rid of the sand, and the same operation of rubbing two together is continued with powdered pumice-stone and water. When perfectly smooth, they are again washed, and afterwards separately polished with a large piece of fine pumice-stone with a circular motion. The polish now given to the stone should be such as to show the reflection of objects to the eye placed close to the stone, and looking along it towards the light.

When a writing or drawing has been fully used, and the stone is to be again prepared, sand is strowed over the surface, and it is sprinkled with water, and rubbed with another stone as before described, till the drawing has disappeared. It must then be washed with aquafortis diluted with twenty times its bulk of water. This is absolutely necessary to destroy the lines, which would otherwise partially re-appear in printing a second drawing from the same stone. After this the stone is again prepared for a new drawing with fine sand in the manner before described.

Ink drawings sink deeper into the stone than the chalk, and require the stone to be more ground away to efface them. The longer drawings remain on the stone, the deeper the ink or the chalk penetrates.

2. Lithographic Ink and Chalk.

For these materials the union of several qualities is required, and as no single substance possesses them all, it is necessary to combine several substances together.

Lithographic Ink.

Ink.

A great many different receipts have been given, but as only two sorts are wanted, namely, one for writing on the stone, and one for transfer, it will be sufficient to give one of the most approved of each kind, and to point out the cause of any defect, with the means of remedying it. These defects are generally to be attributed to some fault in the preparation.

Composition of Lithographic Ink for Drawing on the Stone.

Tallow candle,	2 oz.
Virgin wax,	2 oz.
Shell lac,	2 oz.
Common soap,	2 oz.
Lamp-black, about one-twentieth of the whole.	

These materials are prepared in an iron saucepan with a cover. The wax and tallow are first put in and heated till they ignite; while they are burning the soap must be thrown in in small pieces, one at a time, taking care that the first is melted before a second is put in. When all the soap is melted, the in-

redients are allowed to continue burning till they are reduced one-third in volume. The shell lac is now added, and as soon as it is melted, the flame must be extinguished. It is then necessary in the course of the operation to extinguish the flame, and take the saucepan from the fire, to prevent the contents from boiling over; but if, after the process above described, any parts are not completely melted, they must be dissolved over the fire without being again ignited.

Sometimes a larger proportion of wax is used, when only half of the soap is put in, and the burning goes on till the quantity is reduced one-half. The remainder of the soap is then added over a fire which keeps the mass melted without igniting it.

If the ink, in this state, is broken when cold, the pieces should adhere very slightly when pressed together between the fingers. If it works between the fingers like wax, it must be again burnt for a short time; if it is too brittle, and the broken parts will not adhere at all together by pressure, some more soap must be added in a second burning.

It should now dissolve, though with difficulty, by rubbing with warm water. The lamp-black, of the finest quality, must now be mixed with it, which is done while it is melted over a slow fire, adding small portions of the black at a time, and stirring them well together. The black increases its solubility for use, but too much is detrimental. When complete, it should, in its fracture, have the appearance of Indian ink, though it is softer. When the black is mixed with it, it must be cast on a marble slab and pressed with a heavy weight. The following rules for remedying defects in the ink are given by M. de Raucourt in his *Manuel de la Lithographie*, which is the most useful book yet published on the subject. It has been translated into English by Mr Hullmandel.

Defects of the Ink.

The ink is not soluble.
It is soft and attaches itself to the fingers.

Some time after dissolving it in water it becomes thick and slimy, and requires a continual addition of water in order to be enabled to draw with it.

The ink is not compact, and is full of bubbles.

The ink has no tenacity. It seems composed of scorias.

Remedies.

Add soap.
Burn it more.

This is the defect of almost all inks; it proceeds from its not being sufficiently burnt. Burn it more.

It has been cast too hot on the marble slab; cast it again when it is less hot, and lay a heavier weight upon it.

Both these defects may proceed either from its being too much burnt, or from its containing too much black; in either case, add equal portions of wax and soap, and melt on a slow fire.

Keeping in view the principles here pointed out, any one can, after a few trials, make good Lithographic ink.

Litho-
graphy.

Litho-
graphy.*Ink for Transfers.*

This is composed of the same materials as the preceding, but must be less burned. It will therefore be softer, and it must also be afterwards melted and mixed with a little more wax and thick varnish, such as is described hereafter in speaking of the printing inks.

Lithographic Chalk.

Chalk.

This should have the qualities of a good drawing crayon, it should be even in texture, and carry a good point. It is, however, difficult to avoid making it too soft and greasy on the one hand, and too brittle on the other. For the chalk, as for the ink, more or less of the soap, wax, and tallow, may be used as the extent of the burning may render necessary, and the remedies pointed out for defects of the ink will enable the operator to judge of what is wanting.

The following proportions are the best :

Common soap,	1 ½ oz.
Tallow,	2 oz.
Virgin wax,	2 ½ oz.
Shell lac,	1 oz.

The manipulation is similar to that for the ink. It is well, however, to throw in a little of the wax just before the flame is extinguished. Less black must be mixed with the chalk than with the ink, its only use being to colour the drawing, so that the artist may see the lines he traces.

When the whole is well mixed, it should be poured into a mould, and very strongly pressed to prevent any bubbles, which would make the texture irregular.

3. Mode of Drawing.

With these materials the artist proceeds to work on the prepared stone, taking care first to wipe the stone with a clean dry cloth. The ink being rubbed with warm water like Indian ink, is used on the polished stone; and it is to be observed, that a gradation of tints can be obtained only by varying the thickness of the lines, and the distance at which they are placed apart; as the line traced by the ink being sound and unbroken throughout, receives the printing ink all over. Hence it follows, that the artist cannot gain any advantage by diluting the ink for the lighter tints of the drawing, as the printing ink will take equally upon all the lines, and at once render all of them equally black. The object of the artist is to mix the ink to that consistency, which, while it works freely, shall yet be strong enough to stand perfect through the process of printing. A consistency, a little stronger than writing ink, is sufficient for this purpose.

The chalk will not hold upon the polished stone.

The grained stone, prepared for chalk, being carefully wiped to free it from dust, must be drawn upon with the crayon as common drawing chalk is used on paper. The subject may be traced on the stone with lead pencil or red chalk, but care should be taken to do this very lightly, so as not to fill up any of the grain of the stone. In drawing, the degree of pressure of the hand will vary the strength of the tint, and it is desirable to give the requisite strength at once; as the surface of the stone is a little alter-

ed by receiving the chalk, and hence it does not take any additional lines with the same equality. Practice is necessary to give a command of the material, as it does not work quite like the common crayon, there being great difficulty in keeping a good point. There is also much difficulty in obtaining the finer tints sound in the impression; and for the light tints it is necessary to put the chalk in a reed, as the metal port-crayon is too heavy to draw them, even without any pressure from the hand; and therefore the artist cannot draw them with freedom, as his touch will be unsteady, by being obliged to support the pencil from the stone.

It is necessary to observe the grain with which the stone is prepared, which should vary with the fineness of the drawing. Several pieces of chalk should be prepared to use in succession, as the warmth of the hand softens it.

It is useful to cut the chalk to the form of a wedge rather than a point, as it is less likely to bend in that form.

Small portions of the point will break off during the drawing; these must be carefully removed with a small brush.

4. Printing Press and Roller.

The best sort of printing press for Lithography is *Fig. 1* represented in Plate XCV. the drawings being taken from one used by Mr Hullmandel.

Fig. 1. Is a side elevation of the press, with the scraper partly down.

2. A cross section through the middle.
3. A horizontal plan of the upper part.
4. Detail of the manner in which the scraper is held down during the impression.
5. End elevation of the press.
6. To explain the manner in which the centre of motion of the scraper is raised and lowered.

The press consists of a strong frame, having on the upper part a platten, or bed, *a*, to receive the stone, and which is moved along grooves in the upper part of the frame by means of a star-wheel, *b*, to the axle of which is fixed a cylinder, *c*. On this cylinder the straps, *dd*, are gathered, which work over the pulleys, *e*, fixed to the bed.

When the stone is placed on the bed, and ready for the impression, the frisket, or cover, *f*, of the bed is brought down from the position marked by the dotted outline in *fig. 1*, and shut over the stone, as shown in the same figure. This cover consists of a strong piece of calf's skin, stretched by screws with nuts and hooks, which catch hold of an iron rod sewed along one end of the skin. The other end of it is fixed to the opposite end of the frame. (See *fig. 3*.) The cover is fixed to the bed by hinges, *g*, which can be screwed at different heights, according to the thickness of the stones. When the cover is opened, it rests against the frame, *h*, which can be adjusted to different heights. (See *figs. 1* and *5*.)

The cross piece, *i*, having the scraper, *k*, fixed in it, is now brought down, and the catches, *l*, lock into the upper part of the piece, *n*, sliding between the grooved upright, *m*. This is shown more in detail in *fig. 4*, the upper part, where the catches lock, is of iron, and has a joint and handle to pull it out

Litho-
graphy.

Litho-
graphy.

when the scraper is to be unlocked. A spring, *o*, keeps it generally in an upright position to be ready to hold the catches; *ll*.

When the scraper is locked down, the printer sets his foot on the treadle *p* of the lever, which presses the scraper with great power on the stone. The pressure is by a double lever, having a connecting rod, *q*, which can be adjusted so as to bring the upper arm *r* nearer to the treadle, when an increase of pressure is required, or a thinner stone is placed on the bed, which makes it necessary to bring the scraper lower down. The arm *r* passes through an iron frame on the sliding piece *n*, and thus brings it down when the treadle is depressed. The hook *s* holds down the treadle during the impression.

The star-wheel *b* is now turned round, and by this motion the bed is drawn under the scraper, and the impression is taken. The bed passes over a roller, *t*, which is placed with its centre directly under the scraper. See fig. 2.

As the stones are not always of the same thickness, the scraper must be brought to different heights. Fig. 6 shows an adjusting screw for the purpose of regulating the end farthest from the catches, there being a sliding piece between the grooved uprights, *u*, in which the centre is fixed, on which the cross piece *i* turns. The iron *v*, fig. 2, stops the cross piece and scraper from falling back.

When the bed has been drawn out, the printer releases the treadle, which is raised up by the balance weight, *w*, and the scraper being unlocked and thrown back, the bed is drawn to its first position by the weight, *x*.

As the surface of the stone is not always quite parallel to the bed, a simple contrivance has been adopted to allow a self adjustment of the scraper, which is allowed to turn on the centre, and pressed down by a spring acting on each end, but yielding if necessary at either. It is shown by the dotted lines in fig. 2. The screw *y* presses the scraper lower, or raises it if required.

The scrapers are made of beech wood.

The Roller.

Roller.

The roller for inking the drawing is of the form represented, Plate XCV. fig. 7. The length may vary, but it ought to be full four inches in diameter. It is covered with flannel, rolled tightly three or four times round, and nailed at the ends. It is then covered with a stretched calf-skin, fitting quite tight. The seam must be made neatly with the boot-maker's closing stitch. The ends of the leather are gathered with a string, and tied round the projecting ends of the roller. Loose handles *A, A*, made of thick leather, are put on these ends when it is used. The leather must be put on the roller with the rough side outwards.

5. Printing Ink.

Printing
Ink.

The printing ink is composed, as other printing inks are, of oil, varnish, and very fine lamp-black, well mixed together. To prepare the varnish, a saucepan is about half filled with pure linseed oil, and heated over a fire, till it ignites from the flame of a piece of burning paper. It should then be allowed to burn till it is reduced to the degree re-

quired; and if, during the operation, there appears danger of its boiling over, it must be immediately taken off the fire, and the cover, which ought to fit quite close on the saucepan, must be put on to extinguish the flame. This is to prevent accidents; and the operator cannot be sufficiently cautioned against the danger attending the burning of the varnish, which ought never to be performed in a room with a boarded floor, or indeed in any part of a house. Wet sacks are the best things to put out the flame in case of accident.

Several inks must be prepared, differing in the degree of viscosity, or thickness of the varnish from which they are made, and the quantity of black mixed with them. The longer the oil is burned, the thicker the varnish becomes.

The thinnest varnish is burned till it has lost nearly one-fourth of its volume.

The next till it is reduced one-third.

The thickest till it is reduced one-half.

These directions are to be considered as very general ones; and the state of the varnish is best judged of during the burning, by taking out some with a spoon, and letting a drop fall on a cold earthenware plate, and trying its degree of viscosity with the finger. The thinnest sort should be like common honey, the other should draw out in strings, which will be longer as the varnish is thicker. The thickest will draw out in strings two or three feet long.

It is quite essential to have the oil pure, and the saucepan perfectly clean, and to keep the varnish in clean close jars in a cool place.

It is best not to make the varnish long before it is wanted; for if any decomposition takes place in it, the drawing will be spoiled by the printing ink.

The black is mixed with the varnish on a grinding stone with a muller, in small successive quantities; care being taken that the first portion of black is equally mixed with the varnish before a second is added. In the thickest inks this requires considerable labour.

By mixing the varnishes together, any degree of stiffness of the ink may be obtained; and by putting more or less black, its thickness is regulated.

The printer must always have by him several small pots, each containing a different printing ink, to be used as occasion requires. A small quantity, not more than the size of a hazel-nut, should be used at a time, for it is desirable to charge the roller with as small a quantity as possible. It must be worked well on the colour table with the roller in all directions, that it may be equally distributed all over the roller.

Ink drawings are generally printed with a stiffer ink than chalk drawings.

6. Preparation of the Stone for Printing.

The drawing being finished on the stone as before described, is sent to the Lithographic printer, on whose knowledge of his art the success of the impressions entirely depends. The first process is to etch the drawing, as it is called. This is done by placing the stone obliquely on one edge over a trough, and pouring over it very dilute nitric acid. It is poured on the upper part of the stone, and runs down all over the surface. The stone is then turned, and placed on the opposite edge, and the etching water,

Litho-
graphy.

Etching

Litho-
graphy.

being collected from the trough, is again poured over it in the same manner. The degree of strength, which is little more than one *per cent.* of acid, should be such as to produce a very slight effervescence; after the etching water has lain on the stone for a second or two, its strength must vary according to the heat of the atmosphere, and the degree of fineness of the drawing. It is desirable to pass the etching water two or three times over the darkest parts of the drawing, as they require more etching than the lighter tints. Some stones also, and different chalks, require different degrees of strength of the acid, and experience alone can guide the Lithographer in his practice on this point. Chalk drawings require weaker acid than the ink.

The stone is now carefully washed, by pouring clean rain-water over it, and afterwards with gum-water; and when not too wet, the roller, charged with printing ink, is rolled over it in both directions—sideways, and from top to bottom, till the drawing takes the ink. It is then well covered over with a solution of gum-arabic in water, of about the consistency of oil. This is allowed to dry, and preserves the drawing from any alteration, as the lines cannot spread, in consequence of the pores of the stone being filled with the gum. After the etching, it is desirable to leave the stone for a day, and best not to leave it more than a week, before it is printed from. In some establishments a few proofs are taken immediately after the drawing is etched, but it is better not to do so.

The operation of the etching requires great nicety, and must be done quickly. If the drawing is etched too strongly, the fine tints disappear; if too weak, the printing ink mixes with the darker parts, and the drawing runs into blots. A soft stone requires weaker acid than a hard one, if they are equally pure in quality. The differences in the composition of the stones also require differences in the strength of the etching water, so that no strict rules can be given.

The effect of the etching is, *first*, to take away the alkali mixed with the drawing chalk or ink, which would make the drawing liable to be affected by the water; and, *secondly*, to make the stone refuse more decidedly to take any grease. The gum assists in this latter purpose, and is quite essential to the perfect preparation of the surface of the stone.

7. Printing.

Printing.

When the stone is to be printed from it is placed on the bed or platten of the press; at this time a proper sized scraper for the printing is very carefully adjusted to the surface of the stone. The gum on the stone is now sprinkled with rain-water, and being gradually dissolved, and a wet sponge passed lightly all over it, the printer works the ink which is on the colour table placed beside him, with the roller in all directions till it is equally spread and thinly all over the roller. He then (the stone being wet) passes the roller all over the stone in both directions, observing (as his experience enables him to do) that all parts of the drawing take the ink in due proportion. The roller should be applied with an equal motion and pressure, which must be regulated according to the mode in which the drawing takes the ink; if it does not take it readily, the pressure must be increased, and the roller moved more slowly.

VOL. V. PART II.

Litho-
graphy.

The roller should turn freely as it passes over the stone; if it slips, the cause is either that the stone is too wet, or that too much of the gum remains upon the stone; in the first case, a drier sponge will correct the evil; in the second, the stone must be again washed with a little water; but this must be done with caution, as the gum should not be entirely washed off the stone.

At first the drawing receives the ink with some difficulty, and it is frequently necessary to wet the stone and roll it in several times, before it will take the ink readily. Care must now be taken not to wet the stone too much; the less dampness the better, provided it is sufficient to keep the stone from taking the ink in the parts where there is no drawing; at all events, no drops of water should be seen on the stone, as they spoil the printing ink, and also are imbibed by the roller, which therefore becomes unfit for use. After the drawing is thus rolled in, the sheet of paper is placed on the stone, and the impression taken in the manner described in the account of the press. When, after the impression, the paper is taken up, the stone appears dry, the moisture having been imbibed by the paper. It must be again wetted with a damp sponge, and rolled in with ink as before, taking care to work the roller well on the colour table each time before applying it to the stone.

Generally the first few impressions are imperfect, from the drawing not taking the ink fully, but this is gradually corrected.

During the printing some gum must always remain on the stone (though it will not be visible), otherwise the ink will take on the stone, and also spoil the drawing. If, by too much wetting or by rubbing too hard with the sponge, the gum is entirely removed, some fresh gum-water must be laid on. If the stone has, in the first instance, been laid by with too small a quantity of gum, and the ink stains the stone on being first applied to it, gum-water must be used to damp the stone instead of pure water. Sometimes, however, this may arise from the printing ink being too thin, as will appear below. If some spots on the stone take the printing ink, notwithstanding the above precautions, some strong acid must be applied to them with a brush, and after this is washed off, a little gum-water is dropped on the place. A steel point is here frequently necessary to take off the spots of ink.

The edges of the stone are very apt to soil, and generally require to be wiped with an old sponge or rag after the rolling in. They must also frequently have an application of acid and gum, and sometimes be rubbed with pumice-stone.

Chalk drawings are much the most difficult to print.

After this general description of the printing the following development of the principles on which it is regulated, and notice of the difficulties which arise in its progress, will be found useful.

An ink which is too thin, and formed of a varnish not sufficiently burned, will soil the stone, notwithstanding the proper precautions are taken of wetting the stone, and preparing it properly with acid and gum.

Ink which is too stiff will tear up the lighter tints of the chalk from the stone, and thus destroy the drawing.

The consideration of these circumstances leads us at once to the principles of the printing. These

Lithography.

accidents arise at the extreme points of the scale at which the printing inks can be used, for it is evident, that the only inks which can be employed are those which are between these points, that is, thicker than that which soils the stone, and at the same time thinner than that which takes up the drawing. Lithographers are sometimes unable to print in very hot weather, the reason of this may be deduced from the above. Any increase of temperature will diminish the consistency of the printing ink; the stone will therefore soil with an ink which could be safely used at a lower temperature; hence a stiffer ink must be used. Now, if the temperature should increase so much that the stone will soil with any ink at all less thick than that which will take up the drawing, it is evident that the printing must cease till a cooler temperature can be obtained; for, as the drawing chalk is affected equally with the printing ink, the same ink will tear up the drawing at the different degrees of temperature.

This, though it sometimes occurs, is a rare case; but it shows that it is desirable to draw with a chalk or ink of less fatness in summer than in winter; and also, that if the printing-room is in winter artificially heated, pains should be taken to regulate the heat as equally as possible.

We will now enumerate some other difficulties which are not referable to the above general principle.

If the pressure of the scraper is too weak, the ink will not be given off to the paper in the impression, although the drawing has been properly charged with it. Defects will also appear from the scraper being notched, or not correctly adjusted, or from any unevenness in the leather or paper.

Inequalities in the roller will cause the drawing to receive the ink unequally, and if the roller or its leather is too hard, it will not ink the drawing clearly.

After printing a considerable number of impressions, it sometimes happens that the drawing takes the ink in dark spots in different parts. This arises from the printing ink becoming too strongly united with the chalk or ink of the drawing, and if the printing is continued the drawing will be spoiled. A little consideration will show us the reason of this accident. The printing ink readily unites with the drawing, and being of a thinner consistency, it will by repeated applications accumulate on the lines of the drawing, soften them, and make them spread. In this case it is necessary to stop the printing, and let the stone rest for a day or two, for the drawing to recover its proper degree of hardness. If the drawing should run smutty from any of the causes before enumerated, the following mixture will clean it.

Take equal parts of water, spirits of turpentine, and oil of olives, and shake them well together in a glass phial, until the mixture froths, wet the stone, and throw this froth upon it, and rub it gently with a soft sponge. The printing ink will be dissolved, and the whole drawing also will disappear, though, on a close examination, it can be distinguished in faint white lines. On rolling in again with printing ink, the drawing will gradually reappear as clear as at first.

Accidents sometimes occur in the printing, from the qualities of the paper. If the paper has been made from rags which have been bleached with oxy-muriatic acid, the drawing will be incurably spoiled

after thirty impressions. Chinese paper has sometimes a strong taste of alum; this is so fatal as sometimes to spoil the drawing after the first impression.

When the stone is to be laid by after printing, in order that it may be used again at a future period, the drawing must be rolled in with a *preserving ink*, called by Senefelder, Aetzfarbe, as the printing inks would, when dry, become so hard, that the drawing would not take fresh printing ink freely. The following is the composition of the *preserving ink*.

Thick varnish of linseed oil,	2 parts.
Tallow,	4 do.
Venetian turpentine,	1 do.
Wax,	1 do.

These must be melted together, then four parts of lamp-black very carefully and gradually mixed with it, and it must be preserved for use in a close tin box.

Very good effects are produced in Lithographic prints, by printing from two or more stones with different coloured inks. This is managed by preparing a composition of

Wax,	2 parts.
Soap,	1 do.

A little vermilion.

Melt them in a saucepan, and cast them into sticks. This must be rubbed up with a little water to the thickness of cream, and applied to the surface of a polished stone. An impression is taken in the common way from a drawing, and applied to a stone prepared in this manner, and passed through the press, taking care to mark, by means of this impression, two points in the margin corresponding on each of the stones. The artist having thus on the second stone an impression from the first drawing to guide him, scrapes away the parts which he wishes to remain white in the finished impression. The stone must now be etched with acid stronger than the common etching water, having one part of acid to twenty of water. The whole is then washed off with turpentine.

This plan has been very much followed at Munich. It is generally used to print a middle tint from the second stone. The black impression being given from the first stone, a flat transparent brownish tint is given from the second, and the white lights are where the paper is left untouched. The dots are necessary to regulate the placing of the paper on the corresponding parts of the two stones.

The coloured inks for the tints are differently made, according to the tint required, but the varnishes alone make very good light browns.

The paper for Lithographic Printing should not be so damp as for Copperplate Printing.

8. Different manners of Lithography.

Besides the manners already described of drawing with ink and chalk, Lithography is practised in various other ways.

Transfers.

The most useful of these is the transfer, before alluded to in speaking of the inks, as it saves the labour and inconvenience of writing backwards. This is performed by writing with the composition ink on a prepared paper, and then transferring the writing to a stone, by passing it through the press.

Mixture to clean the drawing while printing.

Bleached paper unfit for Lithography.

Lithography.

That

,

,

Transfers

Lithography.

The paper is prepared as follows. A paste is made by dissolving, with heat, glue or starch in water till its consistency is such as to fix like a thin jelly when cold. It must then be mixed with gamboge and a little alum, in the following proportions :

Glue,	.	.	.	6 parts.
Gamboge,	.	.	.	1 do.
Alum,	.	.	.	½ do.

These must be mixed together over a fire, and applied while lukewarm in a thin coating on one side of a sheet of soft or unsized paper, which, when dry, must be rubbed over with a little powdered gum-sandarac. The writing is to be made with the fatter sort of ink on the prepared side.

When the transfer is to be made, a polished stone is warmed to about 130° Fahrenheit, and placed in the press. The paper is then carefully damped at the back with a sponge, and placed between some sheets of soft paper. It is next placed on the stone with the writing towards it and passed through the press as in printing an impression. This must be repeated four or five times without raising the leather cover of the bed of the press; beginning with a slight pressure at first, and increasing it every time. The press is now to be opened and the paper taken off, when the writing will appear to have come off the paper on the stone. If necessary, the paper may be a little damped, to raise it from the stone, but it should be done with care.

When the stone is quite cold, it is etched and prepared for printing in the usual manner.

This mode is of great use for circular letters and written forms, but does not do so well for works of art, as the lines lose their sharpness by spreading a little at the edges, from the warmth of the stone. To obviate this, Senefelder has proposed a fatter ink, which may be taken off on a cold stone.

Imitation of Wood Cuts.

This is a very easy mode, though not much practised. A polished stone is covered all over with lithographic ink, and the parts which are to be left white are scraped away with a steel point. Very fine lines are most easily obtained by putting them in with a hair pencil. The stone is etched as before described.

Etchings on Stone.

Lithographic Etchings.

A polished stone is prepared for this mode by washing it with diluted acid as weak as the water used for etching a drawing; and after that is washed off, and the stone is dry, it is to be covered with weak gum-water and a little lamp-black. This forms a coating to the stone, and the artist works on it with an etching needle, as in etching on copper. The lines he traces appear white, but look stronger than they will appear afterwards. The stone should be a little warmed, for the needle to work freely through the coating, and care must be taken not to breathe upon it. When the etching is finished, the surface is to be rubbed all over with linseed oil, which penetrates into the lines drawn by the needle. After this the coating is to be all washed off with water.

In this mode lines can be drawn as fine as on copperplate; it is, however, but little practised in England, though it is often employed in Germany.

Lithography.
General Observations on this Art.

The great distinction of Lithography from Engraving is, that it gives a fac-simile of an original drawing, which retains all the freedom and touch of the artist's own hand; while, on the contrary, an engraving must be a copy. This character in a lithographic print arises from the facility with which the drawing is produced; as the process is exactly that which the artist would follow in making a common drawing; and the farther advantage of a great saving of expence is derived from the same cause; for the drawing being made at once on the stone, the whole expence of the engraving is saved. This is particularly the case with drawings in chalk, or with outlines or slight works in ink; and thus the door is opened to the production of many works which could not otherwise be published on account of the expence of engraving.

The more finished drawings in ink, however, have not the same advantages, for the gradations in tint can be obtained only by the variations in the breadth and distance of the lines, which is the same principle as that on which the engraver works; and hence the labour is more nearly equal in the two methods.

It must be admitted, that there is much less difficulty, and consequently less education, required to draw the lines on the stone than to cut them on the copper, but no superiority is obtained in the impression; nor is there any other advantage attending the substitution of the stone for the copper than a saving of expence, which, from there being but few artists who have practised this mode of Lithography, is not considerable at the present time.

The number of impressions which can be taken from a chalk drawing will vary according to the fineness of the tints. A fine drawing will give 400 or 500; a strong one from 1000 to 1500.

Ink drawings and writings give considerably more than copperplates. The finest will give 6000 or 8000, and strong lines and writings many more. Upwards of 80,000 impressions have been taken at Munich from one writing of a Form for regimental returns.

If, however, we compare lithographic prints with fine line engravings, or more particularly with engravings in Mezzotinto, we shall observe, that the latter are more rich in their effect, and that the shadows have, in some places, more depth and brightness. This is in part obtained by cutting deeply into the copperplates, so as to lay on in the impression a mass of ink of a rich and deep black colour in the parts where it is wanted to increase the effect, and by this means the engraver extends the limits of his tints. Lithography will, perhaps, always remain inferior in this respect to line and mezzotinto engraving, as the principle on which it is founded is to print from the surface only. Some of the modes of engraving, such as soft ground etching and aquatint, are inferior to Lithography.

Such may be said to be the present state of Lithography; but it must be recollected, that it is as yet but a new art, and doubtless susceptible of great improvement. It is very much in want of the attention and practice of better artists, who would not only produce better performances with the present materials, but would also be able to point out in

Litho-
graphy
||
London.

what respects the materials might be improved. This want is more particularly felt in England, where Lithography has had to contend with many prejudices; partly from the opposition it has met with from en-

gravers, who consider it as a rival art; and partly from its having fallen into the hands of amateurs whose performances have brought it into a discredit, from which it is but now gradually recovering. (L. L. L.)

London.

LONDON. Since the article **LONDON** in the *Encyclopædia* was written, the extension and improvement of the capital of the British Empire have proceeded with a rapidity equal, if not superior, to what has been witnessed at any former period.

Improve-
ments in the
City.

In the city, or that part properly called London, the increase of buildings and their improvement have not proceeded with an equal pace to what have been exhibited in Westminster, and the other adjuncts, which form a large portion of the metropolis. The private dwellings have been, indeed, much improved and augmented, principally in the environs of Moorfields, and the site which was formerly occupied by the buildings of Bedlam Hospital are now (1821) about to be covered with good dwellings. The most extensive public building recently erected within the city is the new Custom-house, with one front to the river Thames. It is upon a much larger scale than the building destroyed by fire in 1812; its interior is far better arranged for the dispatch of business, and the simple elegance of its front is an addition to the beauty of the banks of the river. The clearing away the ancient and vulgar erections which covered the legal quays between the Custom-house and London Bridge will, when completed, add much to the beauty of that part of the banks of the Thames. The New Mint, on the north-east side of Towerhill, has been completed, and displays much simplicity and taste; but from being crowded by surrounding buildings, its full effect is lost. Though attention has been paid to the exterior of this institution, yet its great excellence consists in the curious, valuable, and accurate machinery by which its operations are effected; for a full account of which, we refer to the article **COINAGE** in this *Supplement*. The inconveniencies of the situation, and of the scattered buildings which form the General Post-Office, have been long subjects of complaint, and at length measures have been taken for erecting a new Post-Office on a regular plan, in a more central part of the metropolis. A piece of ground situated between St Martin's le Grand and Forster Lane, at the north-west corner of Cheapside, has been selected for the purpose, and the houses and warehouses which stood upon it have been purchased and pulled down; by which a good access to Aldersgate Street, and the northern roads from the city, has been formed. The work is at present languishing on account of some differences betwixt the Corporation of London and the Postmaster-General. The estimate of the value of the ground and buildings to be purchased was made to be £240,000; but the actual expences incurred on those purchases has already exceeded that sum; and £87,000 more is required to complete the payment for the whole of the ground and houses. An application was made to Parliament in July 1820, for the additional sum of £100,000. The committee to whom the petition was referred did not approve of the prayer for the grant, and, in consequence of this

state of affairs, the operation must remain suspended, till some new plan for supplying the pecuniary means is adopted by the Legislature. The Prison in the Poultry, called the Counter, has been removed. A new and more commodious edifice has been constructed near Cripplegate, capable of containing 250 delinquents, to which the prisoners have been removed, and the site of the ancient building is now covering with a spacious dissenting chapel. Among the public edifices of an inferior kind within the city that merit notice, may be mentioned the new house built on Moorfields for the London Literary Institution, to which its valuable library and apparatus have been removed. Near to it, on opposite corners of what is intended to form a new square, a very sumptuous Roman Catholic chapel, and an elegant chapel for a congregation of seceders from the Church of Scotland, have been built, the effect of which on the whole of that mass of buildings will be very good, when the plan is completed. The ancient building originally appropriated for a cloth market, known as Blackwell Hall, is now pulling down, and the corporation design building on the spot a range of offices for the Commissioners of Bankrupts, and for other purposes. One of the most striking improvements, because in Holborn, the broadest of all the streets in the city, is that which has been recently effected by removing the cumbrous front of Furnival's Inn, and replacing it with a more modern pile, covered with Bernasconi's composition, which has the appearance of Portland stone. Waterloo Bridge, Southwark Bridge, and Vauxhall Bridge, have all been completed, and opened for the public. As the particulars of their construction have been amply detailed in this work under the article **BRIDGE**, we must refer to it; only adding, that, from want of advantageous approaches, the toll-collected at Waterloo and Southwark Bridges are very inadequate to pay any interest on the capital that has been expended. The ruinous condition of London Bridge has been a subject of complaint for many years, and a Committee of the House of Commons has been appointed, to investigate and report on its present condition, and on the steps necessary to be taken to remove the inconveniencies suffered as well by those who pass over as by the barges and boats that sail under it. Among the improvements to the facilities of the commerce of London must be noticed the docks of the East India Company (see the article **DOCKS**); the West India and London Docks, and the admirable commercial road leading to the two former, by which the goods from those deposits are conveyed to the warehouses in the city. Though not strictly speaking a part of London, yet the East Country Dock, and the Surry Canal, on the southern bank of the Thames, form a vast addition to the facilities of the metropolis, and are now in a complete state to receive shipping. Though the private dwelling-houses within the city

Fig. 1

Fig. 2

London. do not appear to have increased in number within the last ten years, nor have the number of windows increased, yet the value of them must have become considerably greater, as the house tax has advanced from L.86,200, in 1810, to L.103,442, in 1820.

Improvements in Westminster.

The improvements in Westminster that have been made, or that are now (1821) in progress, are very numerous and extensive, both as regards the public erections and the dwellings of individuals. The new churches, whose erection has commenced since the vote of Parliament has destined a large sum to that object, have contributed much to increase the beauty of Westminster. The parish church of St Mary-le-Bone, begun independently of the assistance of government, has been completed, and exhibits a very striking specimen of the architectural taste of the present age. Many others are in a state of great forwardness; but, as these new temples want the elegant towers which arise from the churches built by Sir Christopher Wren, they present, at a distance, less ideas of magnificence than the buildings of that great architect. The completion of the Opera-house and of the adjoining arcade has formed one part of the many additions that have been recently made, and are still proceeding, in the vicinity of the royal palace of Carlton House. Among them the most striking are Regent Street and Place, terminating with the splendid insurance-office which faces the palace. A circular street of uniform houses, with balconies supported by lofty pillars, sweeps round the insurance-office, and connects itself, at the northern extremity, with the magnificent piles of buildings on both sides of a new and wide street, which crosses Oxford Street, and terminates in the Regent's Park. When this plan shall be completed, the mass of buildings will present a group of private dwellings far superior to any thing that is to be seen in any of the other capitals of Europe. The new squares and the streets connected with them which have recently been constructed in the parishes of Mary-le-bone and Paddington, especially Montague and Brianston Squares, exhibit neat and elegant dwellings on spots either disfigured previously by being receptacles of the

filth of the metropolis, or by houses of mean and dirty appearance. The estate of the Duke of Bedford has been covered with handsome streets, and that of the Foundling Hospital, near it, is now converted into Mecklenburg Square and several new streets. On the south-western side of the metropolis the same spirit of building is displayed, and Tottenham-fields is being covered with houses, whilst towards Chelsea, between Grosvenor Place and Sloane Street, the ground is marked out for the construction of spacious squares and wide streets. These improvements do not, however, appear to have increased the number of the dwellings. In fact, the smaller houses have given place to larger; one of which, in many instances, has occupied the space formerly covered by several. The space covered by houses has thus been extended, and the number of streets increased, rather by the demolition of small courts and alleys, and by the new being larger than the old habitations, than by any remarkable augmentation in the number of residences. There cannot, however, be a doubt, that the improvements have tended much to the health of the inhabitants of this extended metropolis.

The portion of the metropolis usually comprehended under the name of Southwark, though it forms no part of that borough, but is within the parish of Lambeth, has partaken of the general spirit of improvement which is displayed in the other portions of the capital. The most remarkable public building is that of Bedlam, a massy pile, constructed with great regard to the nature of the malady of those for whom it is destined, and not destitute of architectural taste. The Cobourg Theatre for performing musical pieces, the Asylum for the Destitute, and the School for the Deaf and Dumb, are among the new public edifices, whilst several streets have been either built, or are now building, connected with the new bridges.

The annexed table exhibits an account of the number of houses charged to the window and inhabited house duties, with the amount of the duties in London, Westminster, and Southwark, for the years 1810, 1812, 1814, 1816, and 1818.

London.

London.
Gas Lights.

The introduction of gas lights into the streets, coffee-houses, and shops, has added much to the brilliant appearance of the metropolis at night. An incorporated company has hitherto furnished this substance, and is now increasing its establishments, whilst a new corporate body has been formed for the farther extension of this mode of lighting. Some late improvements, by which the gas may be produced from oil instead of coal, will tend to lessen the cost of the machinery, to simplify its preparation, and to adopt it for more general, if not universal use.

Fuel consumed.

The consumption of fuel may be considered as fair a criterion as any other, of the increase or decrease of the prosperity of a city. In London coal is almost exclusively used for firing, and, with the exception of a small portion brought from Staffordshire by the Grand Junction Canal, passes through the Custom-house, whose return of imports is as follows:

Years.	Chaldrons of Coals.	Chaldrons of Culm.

Police E.
blishmen

Whilst the Police of the city of London has been left to the care of the municipal magistrates, all of the aldermen being justices of the peace, the vast increase of the suburbs has rendered it necessary to have establishments of a permanent nature in different quarters to prevent depredations, to detect offenders, and to protect the laws and property of the industrious and peaceable. These police offices, which have been of late years increased, are established in Bow Street, Marlborough Street, Hatton Garden, Worship Street, Whitechapel, Shadwell, Queen's Square, Westminster, and Union-hall, in Southwark. To these must be added the Thames police, having hulks in different parts of the river, fitted up as occasional prisons, from whence boats are manned, which row as guard boats through the night in the whole extent of the river, to watch the property on board the different vessels, and on the wharfs that border the water. The principal police office, that in Bow Street, is under the superintendence of a magistrate, with a salary of L.1200 *per annum*, who is in direct communication with the Secretary of State for the Home Department, and of two other magistrates with salaries of L.600 *per annum*. There are three clerks at salaries of from L.150 to

L.300 *per annum*. The officers are eight in number at one guinea *per week*, of whom three have an additional salary of L.200 *per annum* each, for attendance on the royal family. There are thirteen conductors of the patrols at 5s. *per night*, and eighty-seven men under their orders and inspection, at 2s. 6d. *per night* each. The whole expence of this office amounts to about L.12,000 annually. The other seven offices are upon a lower establishment than that of Bow Street; consisting of three magistrates, with salaries of L.600 *per annum* each, of two clerks, and a less number of constables and patrols. The expences of them vary from L.3200 to L.3700 *each* annually. The Thames police office has three presiding magistrates at L.600 *per annum* each, two clerks, seventeen river surveyors, forty-three river constables, five land constables, and a few inferior persons. The expence of this valuable branch of the police amounts to about L.7000 *per annum*. The remaining division of the police of the metropolis is the horse patrol; a body of mounted and armed men, who pass the nights in parading the different roads in the vicinity of the metropolis. The numbers of this body are now about to be augmented, and the whole establishment to be placed on an ex-

London. tended and improved principle. The expence of this department has usually been from L.6000 to L.8000 *per annum*; but what the increase may be under the new system about to be put in activity cannot at present be ascertained. The important branch of the police, which consists in licensing public-houses, is conducted by the county magistrates, who act gratuitously; and to them, at the petty sessions, is committed the superintendence of churchwardens, of overseers of the poor, of surveyors of the highways, and of the appointment of constables; whilst, at the quarter-sessions of the counties that touch upon the metropolis, the trials of offenders of a minor description are allotted.

The returns of crimes and punishments in the city of London and the county of Middlesex are combined, so as to be incapable of being exhibited separately; and those in Southwark and the hundred of Brixton, in the county of Surry, though they form a portion of the metropolis, and contain one-fifth of its inhabitants, are not separately stated in the *Parliamentary Reports*, but are included generally in the list of the crimes and punishments on the Home Circuit of the Judges. We give the returns, therefore, of the trials of London and Middlesex; only remarking, that those of that portion of Surry which forms a part of the capital may be estimated at about one-sixth of the numbers that appear in these tables.

Penitentiary
 Establish-
 ment at
 Millbank.

The *Penitentiary Establishment* at Millbank, originally projected by Mr Jeremy Bentham, is now nearly completed; and the experiment is fairly in progress to ascertain the practicability of producing reformation in offenders by a rigid seclusion from the scenes and companions of their crimes, by constant and regular employment, by the aid of moral instruction, and by the prospect of terminating their imprisonment at an earlier period, as a reward for their good conduct during confinement.

The plan of the institution is calculated for the reception of 1000 prisoners, viz. 600 males, and 400 females; but from the whole of the building not be-

VOL. V. PART II.

ing completed, the numbers, when the last report was laid before Parliament (30th May 1820), were only 180 males, and 213 females. It is expected by the committee, that the whole will be completed in the year 1821. The utility of instruction and discipline is considered, by the committee, to be evinced in the moral improvement and religious impressions which the prisoners have received. As a proof of this, they have given the numbers of those who, at their own request, have been admitted to the holy sacrament, amounting, in 1819, to 40 males, and 89 females; and at Easter 1820 to 143.

London.

The establishment of officers for the Penitentiary is upon a footing nearly equal to what will be necessary when the building shall contain the full complement of 1000 prisoners. The only additions that will be required will be some few inferior turnkeys, matrons, and taskmasters.

The whole amount of expences, from the 1st January to the 31st December 1819, was . . . L. 16,023 3 10

From which are to be deducted the following sums :

Amount of stores remaining on hand in the steward's department on 31st December 1819, L. 1030 14 4

Amount of stores in the master manufacturer's department, . . . 1135 19 10

Monies received and outstanding, for work done by the prisoners out of the prison, . . . 2057 1 6

Value of the work done by the prisoners for the use of the establishment, . . . 1894 7 5

6,118 3 1

L. 9,905 0 9

The males are employed chiefly as tailors and shoemakers, in making great coats and shoes for the military dépôt; but a large portion of the sheeting used in the prison, and some articles of clothing, are manufactured in it. The females are employed in the manufacture of straw bonnets, and in needlework; and they have nearly, from their first beginning, been in constant employment, though, from the low price which women in general receive for their work, their earnings are but inconsiderable. It appears, though the females exceed in number the males, the produce of their labour is very much less, whilst the amount of that for their domestic labour is greater.

Total value of the labour of the prisoners in 1819, - - - L. 2196 14 8

As an encouragement to industry among the prisoners, an exact account is kept of all the work they perform; the wages are divided in the following proportions, and the prisoners, at the expiration of their confinement, are paid what is due to them on that account:

London.

Three-fourths, or fifteen shillings in the pound, or ninepence in the shilling to the establishment.—One-eighth, or two shillings and sixpence in the pound, or three halfpence in the shilling to the prisoner.—One twenty-fourth, or tenpence in the pound, or one halfpenny in the shilling to the master manufacturer, or the matron of the females.—One twenty-fourth, or tenpence in the pound, or one halfpenny in the shilling to the task-master or task-mistress.—One twenty-fourth, or tenpence in the pound, or one halfpenny in the shilling to the turnkeys and the assistant task-master or mistress, to be equally divided among them. Those prisoners who are appointed to the inferior offices of the prison, or are employed in domestic occupations, are entitled to one-fourth of their earnings, the officers having no *per centage* on their labour.

The daily allowance of food for the male prisoners is one pound and a half of bread and six ounces of meat, on four days of each week, with a less proportion for females and boys. On the days when no meat is allowed, a portion of broth is distributed, and every evening a pint of hot gruel or porridge is dispensed to them.

From the marshy nature of the ground on which the building was erected, much apprehension was entertained that it would be injurious to the health of the residents, but the reports of the committee have dispelled such fears. From February 1819 to February 1820, only three deaths occurred, one of which was from fever, and two from consumption. No case of ague had presented itself since the commencement of the establishment, and, at the date of the last report to Parliament, not a single patient in the infirmary was confined to his bed. This healthy state of the prisoners is, by the committee, ascribed to the wholesomeness of the food, to the comparative regularity of their habits, as well as to the warm, though coarse, clothing with which they are supplied, and the care taken of them during sickness.

The number of *Fires* which take place annually in so vast a city, and the losses and deaths thereby occasioned, present a curious subject of inquiry. The only information upon this subject that we have been able to procure, is contained in the *Minutes of the Evidence* taken before the Parliamentary Committee appointed to inquire into, and report upon the state of the Police of the Metropolis. "It was lately stated in an advertisement in the newspapers," says Mr Wilkinson, a gentleman examined by this Committee, "that in the last twelve years six millions of property have been destroyed by fire: I thought it a large estimate, but I mention it to the committee, because it is among the few data that I have upon the subject. I have met with another document with regard to the number of fires that are yearly in London; it is an extract from an article in the *Gentleman's Magazine* for 1807, by a person who says, 'That the Insurance Companies calculate upon an alarm of fire every day, and eight very serious fires every quarter; and from Michaelmas 1805 to Michaelmas 1806, the different fire offices in London experienced three hundred and six alarms of fires, attended with little damage; thirty-

London. one serious fires, and one hundred and fifty-five alarms, occasioned by chimneys being on fire; amounting in the whole to four hundred and ninety-two accidents in the course of twelve months.* Having given some idea of the quantity of property destroyed in London by fire, as far as I was able, I now beg leave to state the loss of lives:—It was stated lately in the papers that seventy lives were lost in the last twelve years, of course limiting the observation to the metropolis. In order to obtain some idea of the number of lives that have been lost in the last eleven years more particularly, I examined the *Gentleman's Magazines*, which I thought a good book of reference, and I now state the numbers that suffered from 1806 to 1816. In 1806 five persons suffered, three of whom were children; in 1807 six persons suffered; in 1808 one person was killed, and one was injured; this was the year in which Drury-lane was burnt, and twenty-four persons suffered by an accident, the ruins falling in upon them; in 1809 four persons were killed; in 1810 ten persons were killed, and three injured; in 1811 three persons were killed, and one injured; in 1812 none, at least none appeared in the *Magazine*; in 1813 five were injured; in 1814 three were killed; in 1815 fifteen were killed, and one injured; in 1816 four were killed, and eight injured; making a total of seventy persons killed, and seriously injured from 1806 to 1816. I have no doubt but several were omitted in the account, for of course they did not profess accuracy as to the number of accidents by fire where persons suffered.—After some consideration on the subject, it is my opinion, that annually in London there are upon an average thirty-five serious fires, and that property to the amount of £100,000 is annually destroyed, and that there is a loss annually of five lives. I have made numerous inquiries as to the number of wilful fires in London, and every one seems to concur in the idea that one-half of the serious fires are occasioned by incendiaries. I beg leave further to state, that upon no occasion has any fire-escape been used at a fire, though I have no doubt, had proper fire-escapes been used, but many lives would have been saved.”*

Newspapers. The number of *Newspapers* published in London is as follows: nine daily morning and six daily evening journals. Seven papers are published three times a week. The *London Gazette*, and two journals in the French language, are published twice in each week. The number of Sunday papers is at present seventeen, and there are eleven other weekly papers. Two journals are published weekly, whose chief design is to criticise and give extracts from new literary works. The whole number of copies of the different journals that are distributed every week, is calculated to be about five hundred and seventy thousand.

British
Museum.

The last accounts presented to Parliament, relative to that splendid national establishment the *British Museum*, furnish the following results:

RECEIPTS of all kinds, including Parliamentary grant of L. 10,000, for the year ending 25th March 1821,	L. 11,789 2 9
PAYMENTS of all kinds for the year ending as above,	10,699 8 6

London
||
London-
derry.

Leaving a surplus in hand, applicable to the expences of the year ending 25th March 1822, of L. 1,089 14

The number of persons admitted to view the Museum, from 27th March 1820 to 25th March 1821, was 62,543. †

Including those parts of Surry usually termed a part of London, the population, according to the returns made to Parliament in 1811, was 1,009,546. By the returns from several districts of the metropolis which we have seen, under the census now in course of being taken, it appears that the increase in the last ten years has been at the rate of rather more than 15 per cent. (w. w.)

LONDONDERRY, a county in Ireland, situated between 54° 56' and 55° 12' north latitude, and 6° 18' and 7° 21' west longitude, is bounded by the ocean on the north, by the county of Antrim on the east, by Tyrone on the south, and by Donegal on the west. Its area, which is of a triangular form, is 798 English square miles, or 510,720 English acres, contained within an outline of about 158 miles. It has Lough Foyle on the north-west, and Lough Neagh on the south-east. The river Foyle, which flows into the first, and the Bann, which issues from the second, are its natural boundaries on the west and east; but the city of Londonderry, with a small district around it, is on the west side of the Foyle, and the town of Coleraine, with a similar tract, is on the north-east of the Bann. The northern side, between the Bann and Lough Foyle, is very narrow, so that the line of sea-coast does not exceed 14 miles. The boundary with Tyrone on the south and south-west is irregular, and much more extensive. Londonderry forms part of the province of Ulster, and is divided into three baronies, viz. Tyrkeerin, Kenaught, and Loughinsholin, and the half barony of Coleraine, with the towns and liberties of Londonderry and Coleraine. It contains thirty-one parishes, of which five belong to the primacy of Armagh, and the others to the diocese of Derry, which also extends into the counties of Donegal and Tyrone and a small part of Antrim.

On the south and south-west the surface is generally mountainous. Another range of high grounds intersects it from south to north, in which last direction the principal rivers have their course. In the valleys through which these rivers flow, there are spots of great beauty and fertility, but of no great extent. Among the mountains which enclose these vallies, the small glens, here called *slacks*, are, for the most part, wild and desolate; yet Samhuil, the highest

* See *Second Report from the Committee on the Police of the Metropolis, ordered, by the House of Commons, to be printed*, 8th July 1817, p. 513.

† See the *Account, &c. ordered, by the House of Commons, to be printed*, 17th April 1821.

London-
derry.

mountain, does not exceed 1600 feet. Every variety of soil is found in this county, but the most valuable kinds, which altogether occupy no great proportion of the surface, are scattered over it in small tracts. Rich loam occurs on the shores of Lough Foyle and Lough Neagh; clay, but not fertile, on the banks of the Bann, and sand in the north-west between Lough Foyle and the sea. Gravel extends over a great part of the eastern side, and also along the river Faughan on the west, and clay and gravel, which are the most common soils, along with bog, occupy a great part of the interior.

The principal rivers are the Foyle, which enters this county from Donegal, and, after a short course, passes into the lake of the same name. It is navigable for large vessels to Londonderry, and to Lifford, in Donegal, for boats of 20 tons. At the Rosses bay, on the east side of the harbour of Londonderry, there is a considerable salmon fishery. The Bann, after a course of near 40 miles, enters Lough Neagh, and then Lough Beg, and forming the boundary with Antrim for the greater part of its course, and afterwards, having the district of Coleraine on the east, falls into the sea four miles below that town. On this river also there is a valuable salmon fishery, and eels are so plentiful, that a few years ago they yielded a rent of about L.2000. The Roe, which has its source near the centre of the county, flows north, and enters Lough Foyle through a tract of low land, which it often inundates. The Faughan rises on the south-west boundary, and taking a direction, during the latter part of its course, nearly parallel to the Foyle, falls into Lough Foyle a little to the eastward. Moyola, a considerable stream, enters Lough Neagh on the south-east. Excepting the Foyle, none of these rivers are navigable. Chalybeate springs are common, but none of them have acquired any degree of celebrity.

Minerals.

The mineralogy of Londonderry has been particularly described by Mr Sampson, the author of the *Statistical Survey* of the county, to which we must refer. The Vale of the Roe separates two districts totally distinct. On the west lies the region of schist, and on the east that of basalt. Flag-stone, blue and white limestone, slate and sandstone, are the only rocks worked. Iron, either in an ochreous state, or mixed with manganese, abounds, but no coal worth notice has yet been discovered. Very fine crystals are found in the basalt, and rock crystal, said to be harder than the Kerry stone, in the schistose region. The lichen, from which cudbear is made, is found on the rocks near Londonderry, and has been long employed by the country people to give their flannels and other woollen fabrics an orange red colour.

Climate.

The range of the barometer, in seven years, from 1795 to 1801, was from 28.37 to 30.84;—of the thermometer, from 17° to 81°; mean temperature 49°; the quantity of rain was from 25.7 to 34.7 inches. In the same period the number of fair days was 129 yearly at a medium. The principal winds are from the west and north-west, which blow for more than half the year. The general character of the climate is humidity, but it deserves this character rather from the frequency of the showers than

fall, than from the quantity of rain indicated by the London-rain gauge.

London-
derry.
Estates.

With the exception of lands belonging to the church, and the towns of Londonderry and Coleraine, and certain portions reserved by the Crown to be afterwards crected into freeholds, the whole of Londonderry was granted by James I. to the twelve companies or guilds of London. The estates are therefore held from these companies, either in perpetuity, or on determinable leases. The principal proprietors or leaseholders are Lords Waterford and Londonderry, Mr Conolly, Mr Ogilby, and the families of Beresford and Ponsonby.

The average size of farms is from five to twenty Irish acres, or at a medium little more than fifteen acres English. Whole districts are subdivided into patches of seven or eight acres; but in a few situations there are farms of upwards of 300 acres. The leases are for a great many different periods, though most commonly for 21 years and one life.

The principal crops are potatoes, barley, oats, and flax. Wheat is not in general cultivation; turnips are very rare, and sown grasses and clovers far from being common. No uniform rotation of crops is recognised in practice, but it is usual to take two crops of oats successively, and sometimes flax the year following. Rorin is the predominating plant in the meadows, where it grows spontaneously with great luxuriance. The live stock presents nothing worthy of particular notice. Grazing grounds are not extensive, and there are few dairies. On the east side of the Bann there are two extensive rabbit-warrens.

The principal manufacture is linen. According to Mr Sampson, the value of the linen bleached in this county exceeds half a million sterling, and brown or unbleached linens are exported in considerable quantities. The flax-seed is chiefly imported from America and Holland. They sow about nine pecks the English acre, if the object be to have fine flax, and little more than half that quantity when the seed is to be saved. The produce is about 160 pounds of rough flax for every peck of seed, which yields from 40 to 48 pounds of milled flax. By the hackle this is divided into nearly equal portions of dressed flax and tow. Hence the produce of an English acre may be about 180 pounds of flax and the same weight of tow, which, according to the prices given in the *Statistical Survey*, would be worth about L.18. The weavers, who are also small farmers, work at the loom little more than half the year. The finer qualities of linen are sold in the Coleraine market, and the coarser at Londonderry. In 1802 there were sixty registered bleachers, who were supposed to finish altogether about 250,000 pieces.

Manufac-
tures.

Londonderry imports iron, hemp, flax and flax-seed, tallow, and tar, from the north of Europe; flax-seed, tobacco, tar, and timber from America; wine from Portugal, and coals, herrings, and other articles from Britain. During war it has sometimes had a considerable share of the provision trade. The principal articles exported are linen, beef, butter, and hides, of which the first is by far the most considerable. The trade by sea is carried on at the ports of Londonderry and Coleraine, but chiefly at the former.

The chief towns are Londonderry, Coleraine, New-Towns.

Commerce.

London-derry town-Limavady, Magherafelt, and Castle-Dawson. Londonderry has a population of about 12,000, and Coleraine near half that number. The villages are Ballaghy, Moneymore, Kilrea, and Dungiven.

The cabins, clothing, food, and fuel of the lowest class of labourers, the cottiers, who form a great part of the population, are much the same as in the Irish counties already described. As the turbaries are fast exhausting, fuel is becoming scarce in the low country. In such situations, when the turf no longer bears to be cut, it is collected into heaps in the state of mire, baked and shaped with the hand, and afterwards spread to harden, but it makes very bad fires; and in some places, even this miserable substitute can no longer be procured but from a distance. The poor inhabitants of the coast, and in the vale of the Roe, employ three months of the year in providing fuel; coal, which is brought from Liverpool and Scotland, selling at a price beyond their means of purchasing. The wages of common labour all the year round may be from 8d. to 10d. a day; in hay and corn harvest 1s. 6d. In 1800, oatmeal, at one time, sold at 4s. 6d. per peck of 10 lb. avoirdupois, and potatoes were proportionally high. In 1811, potatoes were 3d. per stone, beef 6½d. and mutton 7d. per pound, oatmeal 18s. per cwt. Milk 2d. and butter-milk, in summer, ½d. and in winter 1d. per quart.

The county of Londonderry is represented in Parliament by two members, and the towns of Londonderry and Coleraine by another for each. The population in 1790, according to Dr Beaufort, was 125,000; in 1813 it was 186,000. The inhabitants of the mountains are all Catholics, and also one-third of the people of the low country. Of the other religious denominations, the Presbyterians are the most numerous. Their clergy have salaries of from L. 40 to L. 100 from government, the dissenters from the Presbyterian church, as established in Scotland, as well as those who belong to that church.

See Sampson's *Statistical Survey of Londonderry*; Mason's *Statistical Survey of Ireland*, and the works quoted under the former Irish counties. (A.)

LONGFORD is a county in the province of Leinster, in Ireland, bounded on the north by the counties of Leitrim and Cavan, on the east and south by Westmeath, and on the west by the river Shannon, which separates it from the county of Roscommon. In its greatest extent it stretches about 25 miles from north to south, and 20 miles from east to west; and its area is 366 English square miles, or 234,240 English acres, which is divided into six baronies and twenty-three parishes. Twenty-two of the parishes are in the diocese of Ardagh, which is now united to Tuam.

A great part of this district consists of bog, mountain, and waste. On the south, near the river Inny, there is a tract of bog extending to 36,000 acres, and towards the north the county is particularly rugged and sterile. The Inny is the only river of any note which passes through it, and that only for a short distance on the south in its progress towards the Shannon. At its conflux with the Shannon, the latter expands into a lake called Lough Reagh; the only other considerable piece of water is Lough

Gawnagh, on its northern boundary, near which there are rocks of ironstone and some indications of coal. The line of the Royal Canal, from Dublin to Tarmonbarry, on the Shannon, enters Longford on the south, and passes through its south-western quarter. The climate is not more humid than that of other parts of Ireland. At Edgeworthstown, about midway between the Inny and the Shannon, the medium number of fair days, for a period of twelve years, was 140.

Here, as in many other parts of Ireland, much of the land is divided into large estates of from L. 3000 to L. 7000 a year and upwards. Leases are commonly for twenty-one years and a life. Farms are, for the most part, very small where tillage is the principal object; but only a small proportion of the district is under the plough. It is chiefly occupied in grazing, in which the resident gentry almost exclusively employ the farms which they retain in their own hands.

Longford, in common with almost every county in Ireland, has a share of the linen manufacture. Being an inland county, it carries on little other commerce than the exchange of the raw produce of its soil, chiefly oats, with cattle and sheep, for articles required for the use of the inhabitants. The towns are Longford, the county town, where the assizes are held, Ballymahon, Lanesborough, Killashee, Edgeworthstown, the seat of the distinguished family of Edgeworth, Granard, and St Johnstown. None of these is so considerable as to be represented in the Parliament of the United Kingdom.

In 1810, the wages of common labour were 8d. a-day the year round; in hay and corn harvest 1s. 1d. Potatoes were 3d. per stone, beef 5d., and mutton 6½d. per pound, oatmeal 15s. per cwt., and herrings 9s. 4d. the hundred. These wages and prices seem to prove that the condition of the labouring classes is still worse in Longford than in many other parts of Ireland; and it is not easy to conceive how they find the means of rearing families.

The county sends two members to Parliament. The population in 1790, according to Dr Beaufort, was 50,100. In 1808, the Catholics were to the Protestants as eight or ten to one.

See the general works referred to under the former Irish counties, and **LONGFORD** in the *Encyclopædia*. (A.)

LOUISIANA, an independent state of North America; the inhabitants, since its cession by France, having formed a constitution, and been admitted a co-state of the Federal Union. The western boundary of this state, which threatened to become an object of serious contest between the Spanish government and that of the United States, has been at length finally settled, by the same treaty which stipulated the cession of the Floridas. The river Sabina is now fixed on as the boundary between this state and Mexico, in the centre of which is the line of division. This line, including all the islands in the river, proceeds to the thirty-second degree of latitude; from thence, quitting the river, it is continued due north to the thirty-third degree of north latitude; from thence it extends due east, crossing the Red River, till it strikes the Mississippi. That

Louisiana. river continues to be its eastern limit, till it reaches the Iberville, when the line passes through the middle of it, and of Lake Ponchartrain to the Gulf of Mexico; which bounds it on the southern side to the mouth of the river Sabina. All the islands in the Gulf of Mexico, within three leagues of the shore, are included in this state.

The boundaries thus defined are those over which the state of Louisiana, according to the decision of Congress, and the definitions of its own constitution extend, but is far from including the whole of that vast tract of country which was ceded to America. When first ceded, that portion which is now the state of Louisiana was denominated the "Territory of New Orleans;" and that portion which now is denominated the state of Missouri was called the "Territory of Louisiana;" but the rapid peopling of these vast districts has made it necessary to adopt more definite descriptions; and as the settling of the waste increases, and new states are created, the subdivisions, which will be necessary, will give birth to new names for those various districts, which were once called by the general name of Louisiana.

Extent and Population. The state of Louisiana, as thus defined, extends over 49,000 square miles; and though it has rapidly increased since the union with the Federal Government, the population is much thinner than in any of the other states. By the census taken in the year 1810, the whole number of souls was only 76,556, of whom 34,660 were negro slaves, and 7585 free persons of colour.

Since that period no accurate accounts have been made up, but in the latter end of 1818, the inhabitants were estimated to be about 110,000, though, whether the white or the black race has experienced the greatest proportionate increase, is not ascertainable by any returns we have seen.

Revenue. The revenue of this, like the other states of America, is divided into two branches, that destined for the support of the local, and that for the support of the general government. The first of these is not known beyond the limits of the state, but the latter will sufficiently show the relative wealth of Louisiana, as compared with the rest of the union. During the war with England, internal taxes were levied through the states; in 1814, these in the whole produced 3,273,990 dollars, of which Louisiana furnished 33,522; and in the following year, when the whole sum was 6,369,272, the share of this state was only 59,150. The whole net revenue which was produced by the custom-houses of the United States, in 1815, was 97,656,486 dollars, of which Louisiana supplied 984,909.

and Shipping. The whole shipping of the United States employed in foreign trade, in 1815, was 854,294 tons, and that of Louisiana was 13,766 tons; the whole shipping employed in the coasting trade was 435,065 tons, of which only 2577 tons belonged to this state.

This view of the statistics of Louisiana shows most clearly that it is chiefly an agricultural country, whose inhabitants, though possessed of abundance of land, have no more capital than is barely sufficient to enable them to produce as much as they themselves consume. It will appear singular, that whilst the foreign trade has produced one thirty-seventh of

the whole of that branch of national revenue, the internal taxes have amounted to less than one hundredth. This is to be accounted for by observing, that the city of New Orleans, the capital of the state, is the entrepot for the foreign commerce of all the western states; and that the exportable productions of Kentucky, of Ohio, as well as of the other newly formed communities, whose population amounts to nearly one million, have no other place of export. Whatever of European, of West Indian, or of Asiatic commodities, are required by the inhabitants on the banks of the Mississippi, of the Ohio, or the Missouri, must pass the custom-house of New Orleans, and pay there the duties that are imposed by the general legislature. Without this view of the commerce of Louisiana, it would appear that the sums collected by the custom-house alone, independent of the state taxes, would amount to a larger sum per head than is paid by the inhabitants of the richest country in Europe. If, from the population, the slaves are deducted, the taxable inhabitants cannot exceed 70,000; and as the general and state taxes amount to at least 1,250,000 dollars annually, each of the individuals would contribute L. 4 sterling per year for the maintenance of government, which is nearly double as much as is paid by the inhabitants of Great Britain and Ireland, four times as much as is paid in France, and six times as much as is paid in the other kingdoms of Europe.

The state of Louisiana is divided into twelve counties, for the better arrangement in the choice of the legislature: these are,

The County of Orleans,	Rapides.
— German Coast,	Natchitoches.
— Acadia,	Concordia.
— Iberville,	Ouachita.
— Lafourche,	Opelousas, and
Pointe Coupee,	Attakapas.

This division was made in 1812, when the constitution by which the state is governed was first framed. A majority of the convention by which the constitution was enacted was of French and Spanish extraction; but the system decreed assimilates very much to that of the other states in the union, having a governor and two assemblies, of different degrees of duration and property, all elected by those inhabitants who pay taxes. The judiciary department consists of subordinate courts, and a supreme court, with only appellate jurisdiction; the judges of which hold their office during good behaviour, and are only removable on the addresses of the legislative bodies, three-fourths of whose members must concur in the vote. All the elections, as well as the resolutions of the legislative bodies, are determined by ballot. The press is free, but the printers and publishers are accountable for what they issue. No religion is established, nor any provision made for public worship, nor is there any law to prohibit theatrical performances, or the open exercise of trades on the Lord's day. Clergymen, priests, and teachers, of whatever religious sect, are excluded from the legislative assemblies, nor are they eligible to any office of profit or trust under the state.

The city of New Orleans, the capital, contains between 25,000 and 30,000 inhabitants, more than half

Louisiana. of whom are negroes, or people of colour. It has
 /vastly increased since the cession to the United States,
 and its growth of population is rapidly advancing.
 It stands on the eastern bank of the Mississippi,
 about 110 miles from the sea, and is in 30° north la-
 titude. Though it is unfortified, yet it is capable of
 presenting formidable obstacles to the progress of an
 invading enemy; and it is most favourably situated for
 the enjoyment of commerce. Being built on a nar-
 row isthmus, bounded on one side by the river, and
 on the other by impassable morasses, it is difficult to
 be approached. The mouth of the river is defended
 by an almost impregnable fort; and higher up, where
 the river describes nearly a circle, called *Detour des*
Anglois, two strong castles are constructed on the
 opposite banks, which can effectually impede the pro-
 gress of a hostile fleet. The direct passage by wa-
 ter to the city is through several channels, which the
 waters of the Mississippi have forced through the
 land at its mouth. The most considerable of these
 is obstructed by a sand-bank, over which no vessel
 can pass with safety that draws more than seventeen
 feet of water; and though, when this bar is passed,
 the depth of water is sufficient for the largest ships,
 yet it is so encumbered with the huge logs constant-
 ly carried down by the stream as to be a navigation
 of considerable peril. The danger is increased by
 the number of trees, of the heavier kinds of wood,
 that are sunk to the bottom of the river, which ren-
 der the anchorage everywhere insecure, and in con-
 sequence of which the vessels that are detained
 waiting for a favourable wind prefer being moored by
 cables, attached to the trees on the shore, to trust-
 ing their security to anchors on the ground. Besides
 this passage through the mouths of the Mississippi,
 the city of New Orleans has a communication with
 the ocean, by the Lakes Borgne and Pontchartrain.
 A natural canal, called the Bayoute of St John, ex-
 tends from the morasses within two miles of the city,
 to the latter of those lakes, but it is only navigable
 for vessels drawing less than six feet water. It is,
 however, through this channel, that a communication
 is maintained between New Orleans and the northern
 parts of West Florida. The only other towns yet
 known as such in Louisiana are Natchioches, with
 about 600 inhabitants, on the Red River; Natchez,
 on the east bank of the Mississippi, in latitude 31°
 33', with 2500 inhabitants; and Washington, about
 six miles to the east, with 1000 inhabitants.

Mississippi.

The Mississippi usually overflows its banks for
 about one hundred and fifty miles above New Or-
 leans. The floods commonly begin in April, when
 the meltings of the ice from the Missouri make their
 appearance. The increase continues till the end of
 June, when the waters gradually subside; and, in
 August, the stream is confined to the ordinary chan-
 nels. Artificial embankments have been constructed,
 and are vigilantly watched during the increase of the
 river; but, in spite of all efforts, the force of the
 stream sometimes opens a passage for it, and the
 country becomes inundated to a very considerable
 extent. It is remarked by those well acquainted with
 the peculiarities of this river, that whenever an inun-
 dation takes place, as it generally covers a tract of
 country from one of the sinuosities of the river to

another, the quantity of mud which is deposited rai-
 ses the surface of the land several feet, so that it is
 less liable to be overflowed in succeeding years, and
 the deposit becomes the most fertile of soils. The
 right banks of this stupendous river are higher than
 the left, and the land on the western side is least sub-
 ject to extensive inundations, but it is also the least
 fruitful.

Louisiana.

The country to the westward of the Mississippi, Face of the
 between that river and the Colorado, or Red River, country
 and to the westward of that last stream, is intersect-
 ed with numerous lesser rivers, which in some parts
 form extensive lakes. In the valley through which
 the Red River runs is the best land in the state. To-
 bacco and indigo are cultivated there with great suc-
 cess, and the cotton grown is of the best quality of
 any produced within the United States. The prin-
 cipal settlements, for they are undeserving the name
 of towns, are Natchioches, Bayou-Rapid, Bayou-
 Boeuf, Bayou-Robert, and Atchafalaya. Opelousas,
 separated from Attakapas by a natural canal, which
 connects the rivers Teche and Vermillion, enjoys a
 good but very tenacious soil, on which cotton is cul-
 tivated with success, and some sugar is raised. Maize
 is grown for the inhabitants, and vast herds of cattle
 are bred on the extensive natural meadows. The
 number of the cattle belonging to some individual
 proprietors is very great; several mark annually from
 one to two thousand calves.

The settlers of La Fourche are usually that class Agric
 denominated by the French *petits habitants*, small
 proprietors who occupy their own lands; but there
 are some extensive plantations belonging to richer
 individuals, to whom the smaller cultivators are giv-
 ing place, and are removing to new and unexhausted
 soils. Sugar plantations, which can only be esta-
 blished advantageously by capitalists, have of late
 increased considerably. The settlers between La
 Fourche and the canal are principally of Spanish ori-
 gin, and speak but little French. They are a more
 indolent and less enterprising race than the French
 Creoles; are careless about the conveniences of life,
 and their dwellings display a much greater appear-
 ance of poverty than is exhibited by their French and
 English neighbours. That part of Louisiana called
 the Coast, or more properly the German Coast, be-
 tween Pointe Coupee and La Fourche, is the most
 pleasant and most flourishing portion of the state.
 For near 100 miles on the banks of the river planta-
 tions are to be seen, with only short intervals between
 them. These present to view some beautiful woods
 of evergreen oak, of laurels, firs, pines, and prodi-
 gious weeping-willows, and are intermixed with ex-
 tensive groves of orange-trees. In descending the
 river, the smaller proprietors and the white inhabit-
 ants gradually diminish in number, so that near
 the capital the traveller sees ten negroes for one
 white man, and remarks that the appearance of the
 country more resembles the islands in the West In-
 dies, than the other parts of the United States. The
 dwellings in this district are generally wooden frame
 work of one story, but tolerably furnished with con-
 veniences; and the sugar-houses, at distant inter-
 vals, are distinguishable by the columns of thick
 smoke which continually issue from them.

Louisiana.

The productions of the state of Louisiana capable of furnishing the materials of commerce, are so similar to those of the West India Islands, that, like them, the future growth of the state must depend on the increase of the negro population. As the slave trade is prohibited in the United States, as well as in the English, French, and Dutch settlements, the natural increase of the blacks is the only dependence on which the agriculture can rely; and whilst the inequality of the sexes continues, such increase cannot take place. Sugar cannot be made in Louisiana cheaper than in the settlements on the coast of Guiana, nor so cheap as in the viceroyalties of Mexico and New Granada, or in the extensive dominions of Brazil. It is not, therefore, very probable, that Louisiana, notwithstanding the sanguine speculations of the North Americans, will be able to contend on equal terms in the markets of Europe, with the numerous competitors they will have to encounter. The climate, though it admits of the growth of wheat, and the other grains of Europe, at the most northern parts, yet does not produce it with that uniform increase which is experienced in Kentucky, and the newly created States of Illinois and Missouri; and as the transit by steam-boats to New Orleans is very easy, the corn wanted for the consumption of Louisiana can be drawn cheaper and better from these districts, than it can be cultivated at home. Maize and rice are raised with facility, sufficient for the domestic consumption, and furnish the principal aliment to the negro slaves.

Inhabitants.

The basis of the population is French. The inhabitants speak that language, though very corruptly; and in spite of the absence of intercourse with European France during the lapse of three generations, they still retain the quickness, the cheerfulness, and a portion of the politeness of the country from whence they sprung. There are, however, considerable mixtures of Spaniards and Germans amalgamated with the French families, and the whole formed a race, who, with little to stimulate exertion, with very imperfect means of instruction, and with no attention awakened to political investigation, were very ill prepared to receive the republican regimen of the United States. Their religion was the Roman Catholic, to the fasts, and festivals, and ceremonies of which, at least, they were rigidly attached, and the neglect of which, among the Anglo-Americans, made their incorporation with them very tardy and reluctant. At the present day, even according to the accounts of the citizens of the United States, they are murmuring against the government, and indulging sorrow at the change. Much difficulty has arisen from the claims on the land made by the Commissioners on the part of the Federal Government. Under the government of Spain the land was of small value, extensive grants were easily obtained, and as the titles were not likely to be disputed, the evidences of those titles were not very carefully preserved. The commissioners appointed by the States to ascertain those rights are generally accused of great want of liberality, and of discovering a leaning against the claimants. The harvest to the American lawyers, from these disputed titles, has drawn to Louisiana many members of that profession; and as the common

of England, as adopted in the United States, is not easily reconciled to the laws of Spain, which before regulated property in Louisiana, few decisions are made without much delay, great expence, and the bitter complaints of the ancient proprietors, who had been accustomed to a more simple and speedy mode of administering justice. The trial by jury, valued as it is to a people whose customs and manners have been formed by it, is not easily introduced to practical advantage among those who are unaccustomed to it; and the inhabitants of Louisiana neither comprehend its importance or utility, seeing it, as they do, administered by judges who are equally strangers to their language and local customs.

The number of the Aborigines bordering on Louisiana, though much diminished, is still considerable. About thirty-five years ago, the ravages of the small-pox extended to some very distant tribes, and produced an enormous degree of mortality, but since that period they are stated to have been again on the increase. The conduct of the government of the United States towards these uncivilized people has been almost uniformly cruel and unjust, according to the testimony of their most decided panegyrists. The transactions with the Osage Indians may be taken as a specimen of this conduct, and we have the authority of Mr Brackenridge for the narrative. "A purchase was made a few years ago by Governor Lewis, of the greater part of the country claimed by these people (the Osages), reserving to them the privilege of hunting on it. Great dissatisfaction has been excited among them in consequence of the purchase, which they allege not to have been fairly made. In fact, this is not a matter easily effected with strict correctness, and it is doubtful if any of our extensive Indian purchases were conducted in the fairest manner. A desire of doing something meritorious may have induced our agents to go too far in procuring the consent of the chiefs of the nation, and perhaps of chiefs created by themselves for the express purpose. This purchase was sanctioned by the Government of the United States, but the money stipulated to be paid to the Indians was not paid to them. At the end of two years they were informed that the payment was soon to be made. Upon this thirty or forty of the Indian chiefs repaired to the American Governor, and in council remonstrated against the purchase, declaring it to have been unfair. The principal speaker, with much natural eloquence, stated, 'That he was much surprised to hear of this purchase, which had been forgotten by his nation, and, he supposed, had also been forgotten by his great father (the President). The sale was made by those who had no authority, and his great father not having complied with his part of the bargain, by delaying two years the payment, and not performing the other parts of the treaty, his nation ought not to be held to their part of it, even if fairly entered into. But,' said he, 'the Osage nation has no right to sell its country, much less have a few chiefs, who have taken it on themselves to do so: our country belongs to our posterity as well as to ourselves; it is not absolutely ours, we receive it only for our lifetimes, and then to transmit it to our descendants. Our great father is

Louisiana. good and just, will he permit his children to sell the bones of their fathers, to sell the inheritance of their children? No, keep your goods, and let us keep our lands.' The American Governor coolly told the Indians that the President did not compel them to sell their lands, but when they sold them, the bargain must be kept; that payment had been unavoidably delayed; that part of the purchase was ready, which, if they chose, they might accept, if not, it was of no consequence, the land would still be considered as purchased, and their resistance would have no other effect than that of displeasing the President. Finding that opposition was useless, they finally promised to use their influence to induce their nation to accept." Mr Brackenridge reluctantly confesses that these purchases are not less unjust than the French and Spanish mode of taking the land without saying any thing about it, and then keeping these people quiet by presents, more pleasing to them than if given as the payment of a debt, for which an equivalent had been previously received.

The whole of the trade with the Indian tribes may, *communibus annis*, furnish peltry to the amount of 150,000 dollars; it is divided between the British traders of Canada and the traders of America, and is the cause of more jealousy between the two nations, than the whole, if undivided, would justify. It is worthy of remark, that these Indian tribes have names, which seem either to have been recently given to them, or perhaps known to the white race rather than to themselves. The names are altogether different from those by which they were distinguished when the first Europeans traversed the country. Monsieur de la Sale, and the survivors of his unfortunate expedition, who penetrated from the Gulf of Mexico to Canada, in the years 1685, 1686, 1687, and 1688, and visited most of these tribes whose names they registered, have mentioned scarcely a single nation by the name it now bears; neither can the same or similar names be found in the writings of the other early French travellers, Le Clerc, Torty, and Hennepin. The manners of these Indians seem to be but little changed by their intercourse with the white race, and though fire arms have been very generally diffused among them, they have made no other alteration in their mode of carrying on war with each other, beyond that of substituting muskets in the place of bows and arrows.

The climate of Louisiana partakes, in an excessive degree, of those great variations which seem to characterize the whole of North America. The extremes of heat and cold are greater than in the same latitude within the Atlantic states. At New Orleans, the different degrees of cold experienced in two succeeding winters, is frequently greater than is felt in the old continent in a difference of latitude of six or eight degrees. The 30th degree seems, however, to be the boundary of snow in this country, which is a perfect level. In ordinary winters, the ponds and stagnant waters to that limit are rarely frozen, though frost in a slight degree is experienced almost every year at New Orleans. A little to the north of the 30th degree, on lands scarcely more elevated, snow frequently falls, and at Opelousas, in

the year 1807, it continued on the ground more than a week, though it is only in latitude 30° 32', being on the banks of the river in which the fall of water does not exceed one foot in a mile; its elevation, allowing for the sinuosities of the stream, cannot be more than sixty or seventy feet above New Orleans, where, at the same time, the clouds discharged their waters in the form of rain. In the upper part of Louisiana, the winters are more severe than in the same latitudes in the Atlantic states. The thermometer, even in latitude 38°, is often for weeks together from 12° to 15° below zero. The heat of summer is equally excessive, the thermometer frequently from June to August remaining almost stationary, during some hours of each day, as high as 96°. The sudden changes, from the extremes of heat to those of cold, are so rapid, that in a few days from 78 above to 10 below 0, have been remarked as the variations in the thermometer. The north-western part of Louisiana, as it approaches nearer to the rocky mountains, suffers the most severely by the cold of winter. From these excessive variations of climate, combined with the miasmata exhaled from the marshy delta, which extends from the bounds of Florida to the limits of Mexico, the whole of this state may be considered as very unhealthy. Diseases of the intermitten kind everywhere prevail, and in New Orleans, a bilious fever, highly inflammatory, is, if not constantly, yet periodically experienced.

Although the exportable commodities of Louisiana are but of small amount when compared with the great extent of country, and the numerous people that have no other maritime outlet; yet it is naturally capable of furnishing productions of various kinds, which will contribute to the comfort of its inhabitants, and might be made the means of beneficial commerce. Sugar, cotton, and rice, have already been noticed among its productions. Indigo has been cultivated and manufactured, but cannot compete with what is now brought from Bengal and from Guatemala, to the markets of Europe; so that there is no ground to calculate on a great increase. Tobacco seems to be an indigenous plant, as the use of it generally prevailed among the natives when the first Europeans visited the country. What is produced has, when cured, a peculiar flavour which has not been yet relished by those who either smoke, chew, or take snuff. In the capricious rule of fancy, it may however at some time prevail, and if so, will be of vast consequence to the country, as it can be grown with comparatively little expence. Very little wine is yet made in this state; not enough for the consumption of the capital; though most of the planters provide it for their own families. The indigenous grapes are much improved by cultivation, especially two species which are not found in any other part of the United States, the *Vitis arifolia* and the *Vitis riparia*, the latter of which is a very fine grape. On the borders of the savannahs a grape is found resembling that of Burgundy. A wine made from it, if exposed to the sun in summer, and to the cold in winter, becomes much improved, and is not liable to turn sour. Fruits of various kinds grow. The mulberry grows spontaneously, and

Louisiana.

from experiments made upon a small scale, it is clearly ascertained that silk-worms might be easily reared, if the high price of labour did not operate as an impediment. Hemp and flax are found wild, of great length, and of tenacious fibre, but little or no attention has been paid to the cultivation of those plants. Hops also are very abundant in a wild state, but have scarcely received any attention. Plumbs grow in vast quantities, and some of most exquisite flavour. Among other species, one known by the natives as the prairie plum (*Prunus chickasa*), literally covers tracts of ground of many acres in extent, and produces fruit so abundantly as to bend the trees down to the ground with their weight. The persimmon, or, as the French call it, the placminier, is abundant; it somewhat resembles our medlar, but its taste is sweet, and more delicate. When quite ripe, the natives squeeze the fruit over a fine sieve, to separate the pulp from the kernels and skin. The pulp, which is a kind of paste or pap, is then dried in ovens, or in the sun, and is formed into cakes a foot in length, about half a foot broad, and half an inch thick.

This bread is very nutritious, will keep good a long time, but being of a very astringent quality, cannot safely be eaten in large quantities. The papaw trees are found in abundance, and loaded with fruit to a most excessive degree; the bark is highly acrid, but the pulp is both pleasant to the taste and very wholesome. Orange and citron trees were long ago introduced from the island of St Domingo, and produce as good fruit as in their native soils; but the rind of the orange being very thick, it is better calculated for preserving, which is performed to a very considerable extent. Peach and fig trees were early introduced from Carolina. The peaches are of the kind called Albergers, grow as large as the fist, and yield a juice from which both wine and brandy are made. The peach stones are planted in February, and without any farther trouble the trees yield, at least, two hundred peaches the third year, and double that number the six or seven following years, when they cease to bear, and then decay. As new trees are so easily raised, the loss of the old ones causes no regret. The figs are of two kinds, blue and white; they grow to a large size, and are of a good flavour. Wild apples, pears, and cherries, are found, but they are observed to run more to wood, and to produce less fruit than in colder climates. The olive trees grow to a large size, and are sometimes thirty feet from the ground before their branches shoot out; though they are thus more beautiful than the olive trees of the south of Europe, they bear less fruit, and no oil is yet made from them, only the fruit is gathered to be eaten green. Walnut trees, hickory nuts, filberts, and chesnuts, are found in many parts of the country, and with a little attention the fruit of them might be easily increased.

The forest trees most common in Louisiana are white and red cedars, the durable nature of whose wood has induced the settlers to use it generally in building their houses. The cypress is still more durable, and grows to a very large size, so that canoes are frequently made from a single tree, which will carry sixteen or eighteen tons. The bark of the large trees of this species is very valuable as a covering

for the houses of the poorer people. The magnolia, the maple, from which sugar is made, the cotton wood tree, the locust, the holm oak, four kinds of live oak, the elm, the ash, and the beech, are abundantly spread over the country. On the sandy soils near the coast, there are extensive tracts covered with pines, which are used, but not to a great extent, for the purpose of extracting turpentine, tar, and pitch, which may become valuable articles of commerce as the population increases. The myrtle tree, affording wax, is one of the most valuable of the forest trees of Louisiana. It resembles the laurel in appearance, but grows to a much larger size, and its leaves of the same form are of a deeper green. Its fruit grows in bunches, on a stalk about two inches in length. A small pod, containing a kernel within a nut, is covered with the wax, which is separated by the simple process of pouring boiling water upon it, when the wax floats on the top of it. The wax is of two kinds, one a yellowish white, the other a dark green. It may be bleached in six or eight days, is harder than bees-wax, and therefore better fitted for the warm climates, where, in the Catholic churches, it is much used for the large tapers that decorate the altars. When the Spaniards held Louisiana, considerable quantities of this wax were exported to the islands of Cuba and Hispaniola.

As the mineral productions of Louisiana have hitherto been but slightly examined, we must receive with much hesitation the report of their riches. Sanguine speculators in every unexplored country anticipate the discovery of gold and silver mines, and the slightest reports of indications of these metals are readily converted into convictions of their existence. It is very probable that in the district to the north-west of this state such mines may be found, but it is not probable, whilst human labour is so dear, that they can be worked to any profit. Copper, zinc, iron, salgem, and coal, have been sufficiently ascertained to exist, but none of them are worked. The only mineral actually produced is lead. The most considerable mines are worked by the two Indian tribes the Saukees and the Foxes, in a very imperfect mode; but in some years they have produced from 250 to 300 tons of lead. These Indians are ill provided with the proper implements, using generally the common hoe, with which they clear away the soil for a few feet, when the ore is found resembling the state of stones in a quarry. It is smelted in the rudest manner, being laid on piles of wood which are kindled, and the lead, as it is melted, runs into various forms. It is then suffered to cool, and in that state sold to the American traders, who make it into pigs by using the proper moulds for that purpose. The principal district for the production of lead is, however, to the north of the boundary of this state, on the banks of the Mississippi, and within the newly created state of that name. In 1814, those mines employed about 350 persons, and yielded between 700 and 800 tons of lead, so that they are worked to very little advantage, when labour is so high as in the United States.

Among the wild animals of Louisiana, the bears are very numerous in the winter season, when they come from the north in a very lean state, as they do

Louisiana.

Mines.

Wild Animals.

Louisiana. not quit these regions till they are covered with snow. After remaining some time in this country, where the abundance of nourishment soon fattens them, they become very indolent, and take up their residence in some hollow tree, where, when discovered, they are easily taken by the inhabitants, who highly value the oil which they extract from them. These bears are not carnivorous, and, unless wounded by him, will not attack a man, but when they have been assailed and hurt, they have pursued the assailant and squeezed him to death, though without attempting to feed on the body. The *grizzly bear* is seldom seen so far south as this state, nor does the race appear to be very numerous, even in the more northern parts of the continent. It is the enemy of man, and appears to thirst for human food. It grows to an enormous size, and has the property of scenting his prey, so as to pursue a hunter for an hour after he has passed. The American travellers Lewis and Clark give the dimensions of one killed by their party, in crossing the continent. Its length was 8 feet 7½ inches, round the neck 3 feet 11 inches, round the fore-leg 1 foot 11 inches, and the length of the talons 4½ inches. This animal, when full-grown, commonly weighs from 800 to 900 pounds, and has been known to attain the weight of 1200 pounds. He does not, like other bears, climb the trees, and thus the Indian hunters find a means of escape, when pursued by him. Wolves are found in the northern and western parts of the state; they are of much smaller size than the same animal of the old continent, and are not ferocious; they more resemble the native dog of America, and differ but little, except in not barking. The buffaloes have withdrawn towards the interior, and are now rarely found in Louisiana. Deer of various kinds are abundant on the borders, and are hunted by the Indians rather for the sake of the skins than of the flesh, but the value of skins having lately declined, the hunting has consequently much diminished. The prairie dog, or squirrel, is a gregarious animal, occupying large tracts of land, which are filled with its burrows. It has a cloven lip, like the rabbit; the hair is short, and of a light grey colour. It makes a noise not unlike the barking of a small dog, and though, when first taken, it is extremely fierce, it is easily domesticated. The habitations of these animals are in elevated situations, as it wants no water, but subsists on the grass that grows near its burrows, where it passes the winter months in a sleeping state. The *Gopher* bears considerable resemblance to the mole, but is twice as large; its jaw has a bag, or pouch, in which it carries its food, and removes the dirt when he makes his habitation. The mounds thrown up by this little animal are frequently three or four feet in height. The *cameleon* is very common, as well as various other lizards, and the scorpion and tarantula are sometimes found.

The most common of the feathered tribes in the woods are the wild turkeys, which stalk about in numerous flocks, but avoid the open tracts of land. A beautiful bird, called the *Prairie Hen*, is seen in large flights. It comes to the barn yards, and frequently alights on the houses of the villagers. It is larger than the pheasant of the United States, though re-

sembling it in its colours; it differs, however, from it in being much more easily domesticated, nor is the flesh of so good a flavour. Another bird, which has not yet received a name, bears, in appearance, a great resemblance to the pheasant, but is nearly as large as the wild turkey, which is generally double the weight of the domestic turkey of England. Partridges and quails are met with in great abundance; and, in the autumn and winter, the lakes are covered with wild-fowl, ducks, geese, swans, cranes, widgeon, teal, and a variety of others.

The river Mississippi abounds with fish, but the lower part of it is of such great depth that they can only be caught with hook and line. The carp of this river grows to an enormous size, being seldom less than two feet, and sometimes exceeding four feet in length. The higher up the river they are caught, the more they are prized. Barbel are sometimes taken four feet long; the flesh is delicate and good, and in taste resembles the cod of the Banks of Newfoundland. The whole of the rivers abound with cray fish, and the dikes constructed to impede the inundations are frequently so perforated by them as to be exposed to destruction. The shrimps, a diminutive shell-fish, is found on those lakes which sometimes communicate with the sea, as thick as a man's little finger, and three inches in length, and is highly esteemed by epicures. The *Burgo-Breaker*, an excellent fish, is usually a foot or eighteen inches long, perfectly round, with scales of a gold colour. In its throat are two bones, with a surface like that of a file, with which it breaks the coats of the shell-fish on which it feeds. The *Choupic*, of the trout species, the *Sardine*, a kind of pilchard, and the *Patassa*, a sort of mullet, are very abundant, and much esteemed. The sea-coast abounds with all the varieties which are known in the tropical regions, especially turtles of all the different species, and oysters in great abundance.

The country of Louisiana was first visited by the Spaniards, who included it under the general denomination of Florida, in the year 1512. Ponce de Leon, who was the earliest explorer, seems not to have been informed of the magnitude or connections of the river Mississippi, first made known in France by Verazzani, a native of Italy, who visited that country in 1523. No attempt was made to settle it till 1562, when Admiral de Coligny deeming it a suitable place of refuge for the persecuted Protestants of France, equipped an expedition, under Jean de Ribaut. It proceeded only to the spot now known as Savannah, in Georgia, was prevented by the Indians from penetrating to the Mississippi, and, after great disasters and sufferings, returned to France. A second expedition, under René de Laumadere, was dispatched to the same point by Coligny, in 1564, which, after enduring hardships similar to the former, was on the point of reëmbarking for Europe, when the former commander, Ribaut, made his appearance on the coast, with new recruits, and abundance of supplies. The attempt of the French to settle that country excited the jealousy of Spain, and a force was dispatched to dislodge them. The Spaniards, after taking a fort, executed all the garrison, and affixed, on the scaffold

Louisiana. where the barbarities were perpetrated, an inscription that the victims were killed not as Frenchmen, but as heretics and enemies of God. A French officer, De Gourgues, afterwards recaptured the fort, and executed similar cruelties on the garrison, with the inscription that they were destroyed not as Spaniards, but as murderers and cut-throats. The attention of France seems to have been withheld from this colony till about the year 1672, when it was first known in Canada that the river of Foxes ran into a mighty stream, which emptied itself into the Gulf of Mexico. Little, however, was done to explore the course of the river from Canada till the voyage of La Salle, who, after descending the Mississippi, returned to France. He procured the direction of a force, which left Rochelle in 1684, reached the mouth of the Mississippi, and, after building a small fort there, fell a sacrifice to the mutinous dispositions of his own followers. No further notice seems to have been taken of this country by France till about the year 1699, when Iberville reached the river, and ascended it as high as the Natchez. The name of Louisiana was given to the country by that commander, instead of the name of Florida, which both sides of the Mississippi had before borne. The settlement and cultivation of the colony made a very languid progress from the return of Iberville in 1700 till the year 1712, when the government and a monopoly of the commerce of the country was granted to Crosat, who, finding it unaccompanied with profit, relinquished his privilege in 1717. It was thus again at the disposal of the crown, and became the foundation or rather pretext for that project of the celebrated Law which ultimately involved France in such calamities. M. Bienville was appointed governor under the company of the Indies, and selected the spot on which the city of New Orleans stands for the capital of the colony. The war from 1719 to 1721 between France and Spain was extended to this part of the globe, and various events of that warfare tended to check the progress of the settlement, and when peace was restored, the internal dissensions and the animosity of the warlike Indian tribe of the Natchez prevented a rapid increase of prosperity. As late as the year 1736 the establishments were few and inconsiderable, being confined to some settlements at New Orleans, Beloxi, and the Mobile. The war with England, which terminated in 1763, had deprived France of Canada, and Louisiana having thus become of comparatively little value, was ceded by France to the crown of Spain, which, with the greatest reluctance on the part of the inhabitants, obtained possession of it in 1765. It remained under the government of Spain till it was ceded to France by the treaty of St Ildefonso, confirmed by that of Madrid, in 1801. As, from the war between France and us, she could not avail herself of the cession, it remained under the Spanish government till Bonaparte sold it to the United States. Commissioners from France received it from the Spaniards, and instantly delivered it over to the Anglo-Americans in 1803; a short time after which it was formed into an independent state of their union.

The war between Great Britain and the United States having given rise to a variety of predatory in-

cursions on the Atlantic side of America, which compelled the government to adopt a most watchful and expensive state of preparation, was at length directed to Louisiana. The capital, New Orleans, commanding the only channel of communication between the newly-founded and rapidly increasing communities in the western territories, was deemed by the British government a place of sufficient value to warrant the equipment of a most formidable expedition to secure its possession. It is situated on an oblong island on the left bank of the Mississippi. The approach to it was by a pass, about one thousand yards across, below the city, which was defended by the Americans, who had thrown up a hasty line of entrenchments upon it, supported by batteries, and having its flank defended by a fort on the opposite bank of the river. As the fortifications at the mouth of the river forbade the entrance of our fleet, there was no access to the American lines but by passing the army through a series of lakes in open boats. These lakes were defended by a small flotilla of Americans, which was captured or destroyed by a superior force of armed boats from our fleet, and thus a passage was opened for the army to the point to be attacked. The American forces, under General Jackson, were at first very few in number, and for the most part consisted of militia; but during the continuance of the operations, the organised inhabitants of Kentucky and of the other districts bordering on the Mississippi, gave them a numerical superiority, and in the effect of their fire demonstrated that they were equal, if not better marksmen than their assailants. With the British every thing depended on promptitude and decision, with the Americans every delay was of vast benefit. During the preparations for the grand attack the command of the British army had passed from General Keane to General Gibbs, and from him to General Sir Edward Pakenham, from which changes some delay seems to have arisen. The British troops arrived before the American lines on the 24th December 1814, after fatigues and privations of the most severe kind. A continued skirmishing was kept from that period till the 8th of January, in which the British, from their more exposed situation, suffered more severely than the Americans. The attack on the lines of the Americans was made with great vigour in front, whilst a detachment of the army was passed over the Mississippi, and captured the fort that flanked the line of defence. Owing to some confusion in the party appointed to convey the fascines and the scaling-ladders, delays occurred of which the Americans behind their entrenchments most ably availed themselves. Two British generals fell in the attack, the carnage among the troops was dreadful, and at length a retreat was ordered. The officer on whom the command had devolved, seeing but little hope from a renewed attempt, determined on abandoning the enterprise. The forces were withdrawn from the island by the same passages through the lakes by which they had reached it, and having joined the fleet on the coast, were very soon afterwards made acquainted with the termination of the war between Great Britain and the United States. The loss to the British army was very

Louisiana || Louth.
great, for out of betwixt seven and eight thousand men brought into the field, not fewer than two thousand fell. The loss on the American side appears, by their accounts, to have been very inconsiderable.

See Pitkin's *Statistical View of the United States*. Duyckinck's *Constitutions of the United States*. Louisiana, par M. le Page du Pratz. Brackenridge's *Views of Louisiana*. James' *History of the American War*. Stoddart's *Louisiana*. (w. w.)

Situation and Extent
LOUTH is a maritime county in the province of Leinster, in Ireland, containing 329 English square miles, or 210,560 English acres, divided into four baronies and sixty-one parishes. It has the Irish Sea on the east, the counties of Armagh and Down on the north, Meath on the south, and Monaghan and Cavan on the west. From Carlingford bay on the north to Drogheda bay on the south, the distance is about 26 miles. Between these two points, the inland boundary describes the segment of a circle, the greatest distance of which, from the coast, is about 20 miles. Dundalk bay runs up towards the centre of the county, and diminishes its breadth one-half at the town of that name.

Surface and Soil.
Louth has mountainous tracts towards the north, between Dundalk and Carlingford, and on the confines of Armagh; but in other parts the surface is marked by only gentle inequalities, or hills of no great elevation. It is in general fertile, with but little waste land, and no considerable lakes; and is embellished by a number of gentlemen's seats, among which, that of Mr John Foster, on his domain of Collon, is the most magnificent. "No place in the island," says Mr Wakefield, "is more worthy of notice." The Flurry, the Lagan, the Fane, and the Dee, are the principal streams that flow through it, all of them from west to east. The Boyne, for a short distance, washes its south-eastern boundary. Limestone, marl, and slate, are the only fossil substances worked at present; the first is far from being general. Lead was formerly worked on the Lagan, near the sea-coast, and is supposed to exist in the mountains which separate this county from Armagh.

Estates and Farms
This district is divided into estates, worth from L. 1500 to L. 2000 *per annum*. Only two or three are of greater value. Farms are, in general, larger than in most other parts of Ireland; but there are still many very small; in some parishes, scarcely one above 25 acres, and in others they seldom extend to 80 acres. The average rent, in 1809, was from 30s. to 31s. the Irish acre, or about 18s. 6d. the English; but it has increased since, several considerable farms having been let within these five years at from three to five guineas the Irish acre. As the land is chiefly occupied in tillage, little attention is paid to the improvement of cattle and sheep; of the latter, though a few are kept on most farms, the number is inconsiderable. Wheat and oats are the principal corn crops, barley being very little cultivated. The other crops are potatoes, flax, and a little hemp. Clover and turnips are almost confined to the farms of proprietors. It is only in these that the general management is good; that of the common farmers being, for the most part, slovenly,

Louth.
and their lands requiring heavy dressings of lime and marl to keep them productive. Yet many of the tenants are in easy circumstances, well clothed, use meat in their families, and in every thing but their houses and farm buildings are in a condition superior to that of their brethren in most other parts of Ireland. It is common to renew the leases some time before the old ones expire, so that the tenants are not often changed; but fines are frequently paid on these renewals, which carry away much of the capital that should be applied to the soil. Tithes are very seldom taken in kind; their value is ascertained about the end of harvest, and the tenants grant their notes for the amount, which, though payable in November, is in some cases not exacted till almost twelve months after.

Wages and Prices.
In 1816, the wages of common labour were about 1s. a day, and from 1s. 8d. to 2s. in hay and corn harvest. Cottars had only 6d. but they had a cabin, half an acre of land, and grass for a cow, for L. 2, 10s. It is to be regretted, that the writers of Mason's *Parochial Survey*, from which these rates are taken, do not also give the prices of provisions. In 1811, according to Mr Wakefield, potatoes were 3d. *per stone*, oatmeal 19s. 3d. *per cwt.* and beef 6d. and mutton 7d. *per pound*. Coal is used among the better sort of farmers, but the most common fuel is turf, and among some of the poorest cottars only furze. Mr Wakefield saw a number of women upon the fields, between Collon and Dundalk, gathering dry dung to serve them as fuel; and this practice, he adds, is common over all the county.

Manufactures
Louth carries on the linen manufacture to a considerable extent. About 2000 acres have been under flax in some years, and in one year 11,590 bushels of seed have been saved. This quantity of seed is much greater than is produced in any other county of Ireland. Dowls, sheetings, and other fabrics, are made to a great amount, and sold at Drogheda, from whence they are sent, partly in an unfinished state, to the English markets. At Collon they make linen of various qualities, part of which is also sold unbleached. The weavers earn about 1s. or 2s. 3d. a day. Cambrics have long been manufactured at Dundalk. The cotton manufacture, also, was in a flourishing condition at Collon when Mr Wakefield wrote; 1300 looms being employed in calico weaving by two individuals in that neighbourhood, at wages nearly the same as those of the linen weavers. A stocking factory has also been established at Collon.

Towns
The towns are Drogheda, Dundalk, Carlingford, Dunleer, Ardee, and Collon. Drogheda, situated on the north bank of the Boyne, which is navigable to the town, its liberties extending into the county of Meath, is a place of considerable trade, with a population of 15,000. Large quantities of corn are shipped here for the English market, particularly for Liverpool, which lies nearly on a line with it on the opposite coast. The battle of the Boyne is commemorated by an obelisk erected on the banks of the river, at the second milestone from this town on the road to Slane. Dundalk, the shire and assize town, though its harbour is not so good as that of Drogheda, is a place of importance both for its

Louth
||
Luc.

trade and population. At Dundalk, Edward, the brother of Robert Bruce of Scotland, was proclaimed King of Ireland, the last of its resident monarchs, if his short and precarious dignity entitle him to the name. Carlingford, situated on the bay of that name, is an inconsiderable place; its harbour being unsafe in rough weather, is little frequented by shipping except for the export of butter. Dunleer and Ardee, though parliamentary boroughs before the Union, have been many years in a state of decay. Collon, which owes much of its increase to Mr John Foster, is now a considerable village, pleasantly situated on the highly ornamented domain of that gentleman.

Representa-
tion and
Population

Louth county returns two members to Parliament, and the towns of Drogheda and Dundalk one each. Lord Roden and Mr John Foster have a commanding influence both in the county and in the borough of Dundalk. In 1790 the population was 57,750, in which, according to Mr Wakefield, the Catholics are to the Protestants as fifteen to one. Much of the personal property belongs to the former, and considerable estates are held by Lord Southwell and other Catholics. Two Catholic gentlemen are called on the grand jury. From the increase in some of the parishes, described in the *Parochial Survey*, it is probable that the population of this county had increased considerably, perhaps one third, since 1790.

See the general works referred to under the former Irish counties, and the articles LOUTH, DROGHEDA, and DUNDALK, in the *Encyclopædia*. (A.)

LUC (JOHN ANDREW DE), a natural philosopher of great merit and celebrity, born at Geneva, 8th February 1727, was the son of James Francis de Luc, descended from a family who had emigrated from Lucca, and settled at Geneva, in the fifteenth century.

His father was the author of some very respectable publications in refutation of Mandeville, and other sceptical writers; and he had the means of giving his son an excellent education, although he found it convenient to establish him in a commercial engagement, which principally occupied the first forty-six years of his life, without any other interruption than that which was occasioned by some journeys of business into the neighbouring countries, and a few scientific excursions among the Alps: during these, however, he collected by degrees, in conjunction with his brother William Antony, a splendid museum of mineralogy and of natural history in general, which is still preserved at Geneva by the younger Deluc, his nephew. He took, at the same time, his share of the public business of the state, as one of the council of 200, and he is still remembered with respect by his fellow citizens, though he revisited them but once, and that for a few days only, after his emigration, which was the consequence of some unexpected misfortunes in commerce. He bore them with fortitude, and he rather rejoiced than lamented at the change of his pursuits, when he removed to England in 1773. He was made a Fellow of the Royal Society in the same year, and was appointed Reader to the Queen; a situation which he continued to hold for forty-four years, and which

afforded him both leisure and a competent income. In the latter part of his life he obtained leave to perform several tours in Switzerland, France, Holland, and Germany; in this last country he passed six years, from 1798 to 1804; and after his return he undertook a Geological Tour through England. When he was at Gottingen, in the beginning of his German Tour, he received the compliment of being appointed Honorary Professor of Geology in that University; but he never entered on the active duties of a professorship. He was also a Correspondent of the Academy of Sciences at Paris, and a member of several other scientific associations.

His favourite studies were geology and meteorology. The situation of his native country had naturally led him to contemplate the peculiarities of the earth's structure, and the properties of the atmosphere, as particularly displayed in mountainous countries, and as subservient to the measurement of heights. He inherited from his father a sincere veneration for the doctrines of Christianity, and a disposition to defend the Mosaic account of the date of the creation, against the incredulity of the age. His royal patroness was most anxious to encourage and promote his labours in this field; and he is universally allowed to have had great success in removing the specious objections which had been advanced by his antagonists, against the comparatively recent formation of the present continents. The testimony of Cuvier is sufficient to establish his character in this capacity, and to place him, at the same time, in the first rank of modern geologists. His original experiments, relating to meteorology, are, however, not less valuable to the natural philosopher; and he discovered many facts of considerable importance relating to heat and moisture. He noticed the disappearance of heat in the thawing of ice, about the same time that Black founded on it his ingenious hypothesis of latent heat: he ascertained that water was more dense about 40° of Fahrenheit than at the temperature of freezing, expanding equally on each side of the maximum: and he was the original author of the opinion lately readvanced by Mr Dalton, that the quantity of aqueous vapour, contained in any space, is independent of the presence or density of the air, or of any other elastic fluid; though it appears difficult to reconcile this opinion with some of the experiments of our author's great rival, Saussure, a philosopher who, as he very candidly allows, made, in many respects, more rapid progress in hygrometry than himself. Deluc's comparative experiments on his own hygrometer, and on Saussure's, show only that both are imperfect; but it may be inferred from them, that a mean between both would in general approach much nearer to the natural scale than either taken separately. It appears also probable, that Saussure's is rather less injured by time than Deluc's, which has been found to indicate a greater degree of mean moisture every year than the last.

He was a man of warm feelings, and of gentle and obliging manners, fulfilling on all occasions the various duties of a husband, a father, a master, and a friend; at the same time, that his literary and scientific merits, and his unremitting attention to

Luc.

Luc. the service of the Queen, ensured her respect and her kindness; he saw her daily for many years, and in his last illness, which was long and painful, she showed him repeated marks of benevolent regard. He died at Windsor, on the 7th of November 1817, leaving a variety of works, which will long be remembered in the scientific world.

*1. *Recherches sur les modifications de l'atmosphère*, 2 v. 4. Geneva, 1772. 4 v. 8. Par. 1784. Containing many accurate and ingenious experiments on moisture, evaporation, and the indications of hygrometers and thermometers, applied to the employment of the barometer in the measurement of the height of mountains.

2. *Relation de différens voyages dans les Alpes de Faucigny*, 12. Maestricht, 1771. Written principally by Dentand, who accompanied the two Delucs in these expeditions.

3. *Account of a new hygrometer* Phil. Trans. 1773, p. 404. Like a mercurial thermometer, with an ivory bulb, which expanded by moisture, and caused the mercury to descend.

4. *Rules for measuring heights by the barometer*. Phil. Trans. 1771, p. 155. The first correct rules that had been made public.

5. *Barometrical observations on the depth of the mines in the Harz*. Phil. Trans. 1777, p. 401. Examples of the application of the rules.

6. *An essay on pyrometry and areometry*. Phil. Trans. 1778, p. 419. A paper containing many valuable remarks on physical measures in general.

7. *Lettres physiques et morales sur l'histoire de la terre*, 6 v. 8. Haguenau, 1778. Dedicated to the Queen; relating particularly to the appearances of mountains, and to the antiquity of the human race; explaining the six days of the Mosaic creation as so many periods, preceding the epoch of the actual state of the globe; and attributing the deluge to the filling up of cavities, supposed to have been left void in the interior of the earth. The whole work is intermixed with interesting observations on men and manners.

8. *A second paper concerning some barometrical measurements in the mines of the Harz*. Phil. Trans. 1779, p. 485.

9. *Lettres sur quelques parties de la Suisse*. 8. 1781. Also addressed to the Queen.

10. *Nouvelles idées sur la météorologie*. 2 v. in 3. 8. Lond. 1787. A very valuable collection of observations and experiments, including some original remarks on electricity.

11. *Several papers on hygrometry, on vapour, and rain, on meteorology in general, on expansion, and on refraction*, in Rozier's *Journal de Physique*, XXX., XXXII., XXXVI., XXXVII., XLIII.

12. Some letters *On the physical history of the earth*, in the *Monthly Review*, enlarged, especially June 1790, and Vol. II. Appendix.

13. *On hygrometry*. Phil. Trans. 1791, p. 1. 389. In one of these very important papers, the whalebone hygrometer is described.

14. *On evaporation*. Phil. Trans. 1792, p. 400. Among the fundamental principles laid down in this paper, the independence of vapour and air is asserted.

15. *Lettres sur l'histoire physique de la terre*. 8.

Par. 1798. Addressed to Professor Blumenbach, and published by Mr. Emery, a clergyman at Paris. The substance had already appeared in the *Journal de Physique* for 1790, 1791, and 1798. We find in this volume an essay written for a prize at Haarlem, in 1791, but without success, *On the existence of a general principle of morality*. It contains an interesting account of some conversations of the author with Voltaire and Rousseau.

16. *Lettres sur l'éducation religieuse de l'enfance*, 8. Berlin, 1799.

17. *Bacon tel qu'il est*. 8. Berlin, 1800. Showing the bad faith of the French translator, who had omitted many passages favourable to revealed religion.

18. *Précis de la philosophie de Bacon*. 2 v. 8. Par. 1802. Giving an interesting view of the progress of natural science.

19. *Lettres sur le Christianisme*, Berlin and Hanover, 1801, 1803. A correspondence with Mr. Teller.

20. *Introduction à la physique terrestre par les fluides expansibles*. 8. Par. 1803.

21. *Traité élémentaire sur le fluide galvanique*. 8. Paris, 1804.

22. *A paper on lavas*. *Journal des Mines*, cxv. Nicholson, XX.

23, 24. Several articles in the *British Critic*, and in the *Monthly Magazine*.

25. *Traité élémentaire de géologie*. 8. Paris, 1809. Also in English, by Delafite, the same year. This volume is less strictly introductory to geology than the *Lettres sur la terre*. It is principally intended as a refutation of the Vulcanian system of Hutton and Playfair, who deduced the changes of the earth's structure from the operation of fire, and attributed a higher antiquity to the present state of the continents than is required in the Neptunian system adopted by Deluc after Dolomieu.

26. He sent to the Royal Society, in 1809, a long paper *On separating the chemical from the electrical effects of the pile*, with a description of the *Electric column and aerial electroscope*; in which he advanced opinions so little in unison with the latest discoveries of the day, especially with those of the present President of the Society, that the council probably thought it would be either encouraging error or leading to controversy to admit them into the *Transactions*. He had, indeed, on other occasions, shown somewhat too much scepticism in the rejection of new facts; and had never been convinced even of Mr. Cavendish's all important discovery of the composition of water. The paper was afterwards published in Nicholson's *Journal* (XXVI.), and the dry column described in it was constructed by various experimental philosophers. It exhibited a continual vibrating motion, which was made more sensible by the sound of a little bell, struck by the pendulum at each alternation; and the vibration was more or less rapid, according to the state of the atmospheric electricity, and according to other circumstances affecting the column; but the motion ceased at last, after a continuance of several months, or perhaps years. There are also papers in *Voluemes* XXI. XXII. XXVII. XXVIII. XXXII. XXXIII. and

Luc.

Luc
||
Lucimeter.

XXXV., mostly *On electricity and galvanism*, together with one on *hygrology*, a *Letter to Bode on comets*, and a fanciful theory of the origin of the *Heat derived from compression*; some of them are dated from Ashfield, near Honiton, in Devonshire.

27. In the *Philosophical Magazine*, Volumes XXXV. XLII. XLIII. and XLV., there are also some papers *On electricity and geology*, especially on that of *St Michael's Mount*, of *Vesuvius*, and of *Northumberland*; and a note *On the sympathetic vibrations of the pendulums of two clocks*, placed near each other.

28. *Geological travels in the north of Europe*. 8. Lond. 1810.

29. *Geological travels in England*. 2 v. 8. Lond. 1811.

30. *Geological travels in Switzerland and Germany*. 2 v. 8. Lond. 1813.

31. An "Abridgment of geology," published in 1817," when he was in his ninetieth year, is mentioned as one of his best works; but it seems to have been only a republication or a translation of some former treatise, perhaps the *Traité élémentaire*.

[*Philosophical Magazine*, Nov. 1817. MONOD and WEISS, in *Biographie Universelle*, XXV. 8. Paris, 1820.] (O. R.)

LUCIMETER.—This name has been given to an apparatus employed by Bouguer for measuring the intensity of the light which proceeds from different bodies.

In the case of two lamps or candles burning near to each other, the intensity of the light may be compared, by comparing the intensity of the shadows of an adjacent body. The shadow produced by interposing the body in the stronger light is darker than its shadow, formed by the interposition of the body in the rays of the weaker; because the first shadow is enlightened only by the light it receives from the weaker light, whilst the other shadow is more strongly enlightened by the light from the stronger light. But this method will not serve for comparing the intensity of the light of the sun and moon, for the light of the sun so greatly exceeds the other, that when both sun and moon are visible at the same time, the light of the moon is far too weak for any shadow to be formed by intercepting it.

For the purpose of measuring and comparing the intensity of the light of the sun and moon, Bouguer reduced the light of the sun and of the moon till the light appeared to be equal to that of a candle. The eye is able to judge whether or not two lights are equal; but if the lights are unequal, it is impossible to estimate by inspection how much the one exceeds the other. Being able to calculate how much he had reduced the light of the sun and of the moon, he was enabled to say what proportion their light bore to that of the candle.

For the former, Bouguer, when the sun was at an elevation of 31 degrees above the horizon, received the light into a dark room, through a hole of $\frac{1}{16}$ of an inch in diameter. In this hole was placed a concave glass to weaken the light, by making the rays diverge more than they would in passing through the hole without a concave glass. He received the image formed by the divergent rays at a distance of five or six feet, by interposing a screen, which form-

ed a right section of a cone of divergent rays: this right section was a round image of the sun, of $\frac{108}{16}$ of an inch in diameter; therefore the light was diminished by the square of that number 11,664, since the light received through a hole of one line in diameter was diffused over a circle of 108 lines in diameter, and of 1164 times the area. This light he found equal to that of a candle placed at a distance of 16 feet. Lucimeter.

He employed the same concave glass to receive the light of the full moon; the moon being nearly at its mean distance from the earth, and at 31 degrees of altitude; the same altitude as the sun had in his observation of that luminary. The light of the moon being weak, he received the image at $\frac{1}{16}$ of an inch from the concave glass, and then the light of the image was so weak as to be equal to the light of a candle at the distance of 50 feet.

Now the light of the moon was diminished in the proportion of the square of one to sixty-four, which is the square of the diameter of its circular image. If the light of the moon had been diminished 11,664 times, it would have been equal to the light of the candle removed to a distance of 675 feet; for as 8, the diameter of the image, is to 50, the distance, so is 108 the diameter of the image when the light is reduced 11,664 times, to 675 feet, the distance of the candle, which would produce that degree of light. Therefore the light of the sun being equal to that of a candle placed at the distance of 16 inches, and the light of the moon being equal to the light of the same candle placed at the distance of 675 feet, that is, 8100 inches, it follows that the light of the sun is to the light of the moon as 65,610,000, the square of 8100, is to 256, the square of 16. This experiment gave the light of the sun 256,289 times greater than the light of the full moon. Bouguer had results somewhat different from other experiments, and taking a mean of these results, he concludes that the light of the sun is 300,000 times greater than the light of the full moon. The light of the moon, when collected into a focus by a concave mirror, which condenses the light into a space 306 times less than the natural state of the light, produces no sensible heat.

Bouguer found, by a process similar to that above described, that the light of the full moon, when elevated 66° 11', was to the light of the full moon elevated 19° 16' above the horizon, as 2500 the square of 50, to 1681 the square of 41. The sun at the harbour of Croisic in Brittany, where Bouguer made his experiments, has the same apparent altitudes of 66° 11' and 19° 16' at the summer and winter solstices; and he concludes that the intensity of the light of the sun at the summer solstice is to the intensity of its light at the winter solstice, in the above mentioned ratio of 2500 to 1681, or about three to two. He found that the light of the moon when near the horizon, and about to set, was 2000 times less than the light of the moon elevated 66° 11'. This difference in the light of heavenly bodies, when at different altitudes, proceeds from the want of transparency in the air; for when the heavenly body is not much elevated above the horizon, the rays proceeding from it have a greater distance of atmosphere to pass through

Lucimeter than the rays from the same body at a greater altitude; and the rays from a heavenly body in the zenith proceed in the direction of a diameter, and therefore traverse the atmosphere by the shortest path. Bouguer calculates that the mass of air passed through by the rays from a heavenly body at $66^{\circ} 11'$, is equal to a supposed mass of air of the uniform density of the air at the surface of the earth, 4275 toises in thickness; and that the mass of air passed through by the rays from a heavenly body $19^{\circ} 16'$ in altitude, is equal to a supposed mass of air of the density of the air at the surface, and of 11,744 toises in thickness.

He concludes that light is diminished $\frac{1}{2500}$, or about $\frac{1}{4}$, by passing through a mass of air of the uniform density of the air at the surface, and 7469 toises in thickness. The rays from a heavenly body near the horizon are likewise impeded by the terrestrial vapours, which vary in density, and render the intensity of the light of a heavenly body at the horizon various at different times. The same cause renders the quantity of the refraction of the heavenly bodies at the horizon uncertain.

In certain states of the air, the discs of the sun and moon, when at the horizon, appear somewhat elliptic; the apparent vertical diameter being less than the horizontal. This is occasioned by the greater refraction of the air through which the under limb is seen; which refraction elevates the apparent place of the under limb, by a quantity sensibly greater than that quantity of refraction by which the upper limb is raised. This alteration of figure, and the colour of the rising and setting sun and moon, indicate the greater or less quantity of vapour diffused in the air, and are usefully referred to by the seaman and farmer as prognostic indications of the weather.

Lucimeter The existence of a greater or less quantity of vapour mixed with the air is also indicated by the different degrees of intensity of the blue colour of the sky. Some are of opinion, that this colour depends on the colour of the mass of air which forms the atmosphere; others maintain, that it arises from the darkness of space seen through the interposed atmosphere. The blue colour of the sky increases in intensity from the horizon to the zenith, and is particularly intense when seen from the elevated parts of the Alps, because in that situation there are few terrestrial vapours mixed with the air, and it is the white colour of these vapours which renders the blue less intense in lower situations. For the purpose of estimating and noting its intensity, it is compared with different tints of blue painted on a card, as described under the article CYANOMETER.

See *Essai d'optique sur la gradation de la lumiere*, par Bouguer; and *Voyage de Humboldt—Relation historique*, Chap. III. p. 251. (Y.)

LUS, a district in the eastern part of the Persian province of Mekran. It is of a circular form, and bounded on three sides by an immense range of mountains. The face of the country is flat and sandy, producing abundant crops of every species of grain. There are four passes through the mountains, two of which lead into Sind, one into Mekran, and one into Balouchistan. The present chief, Jam Meer Mahomed Khan, can bring into the field 4000 irregular troops, and draws a revenue of 50,000 rupees. The different towns and districts are governed by petty chiefs, independent in their district, though owning the supremacy of Mahomed Khan. The capital is Bayla, but the chief maritime port is Sommeany. Lus is supposed to be the country of the ancient Oritæ.—*Edinburgh Gazetteer, or Geographical Dictionary*.

M A L

MALUS (STEPHEN LEWIS), the discoverer of the Laws of the Polarisation of Light, born at Paris, 23d June 1775, was the son of Anne Lewis Malus du Mitry, and of Louisa Charlotte Desboves, his wife.

His father had a place in the Treasury of France, and gave him an excellent education at home in mathematics and in the fine arts; as well as in classical literature, with which he rendered himself so familiar, as to retain many passages of the *Iliad* in memory throughout his life. At seventeen he was admitted, after a severe examination, as a pupil of the School of Military Engineers; and about the same time he amused himself with writing a regular tragedy in verse on the death of Cato. He soon distinguished himself in his military studies, and he was about to obtain a commission as an officer, when an order of the minister Bouchotte imputed to him the offence of being a suspected person, probably on ac-

count of the situation held by his father, and he was dismissed from the school. He was then obliged to enter the army as a private soldier in the 5th battalion of Paris, and he was employed in this capacity on the fortifications of Dunkirk. Here he was soon distinguished by Mr Lepère, the director of the works, as superior to his accidental situation; and he was selected as one of the young men who were to constitute the members of the *Ecole Polytechnique*, then to be established upon the recommendation and under the direction of Monge, who immediately chose him, from a previous knowledge of his merit, as one of the twenty that were to be made instructors of the rest. This body constituted, at that moment, the only refuge of the sciences in France, and the enthusiasm of its members was proportionate to the advantages which they enjoyed, and to the importance of the trust committed to them. In the three years which he passed in this institution, he was

Malus.

much employed, among other applications of the higher geometry, in pursuing the mathematical theory of optics, a department of science in which he was afterwards so eminently to distinguish himself by experimental discoveries. He was then, however, obliged to abandon for a time the pursuit of scientific investigations, and he was admitted into the corps of engineers, with the seniority of his former rank in the school. He served in the army of the Sambre and Meuse; he was present at the passage of the Rhine in 1797, and at the affairs of "Ukratz" and Altenkirch. While he was in Germany, he formed an engagement with Miss Koch, the daughter of the Chancellor of the University of Giessen, and he was on the point of marrying her, when he was obliged to join the Egyptian expedition. He was present in that campaign, at the battles of Chebreis, and of the Pyramids; he was at the affair of Sabish, at the siege of El Arish, and at that of Jaffa. After the surrender of that place, he was employed in the repairs of the fortifications, and in the establishment of military hospitals. Here he was attacked by the plague, and fortunately recovered from it without any medical assistance. He was then sent to fortify Damietta; he was afterwards at the battle of Heliopolis, at the affair of Cerain, and at the siege of Cairo. After the capitulation with the English, he embarked on board of the transport *Castor*, and arrived in France the 26th October 1801. His health was exhausted, and his spirits were broken, by fatigue and anxiety; but his attachment to his betrothed bride was undiminished, and he hastened to Germany to fulfil his engagement: his fidelity was rewarded, during the eleven years that he survived, by the most constant and affectionate attention on the part of his wife; and she died a year or two after him, a victim to the same disease which had been fatal to her husband.

He had, however, enough of strength and vigour of constitution remaining, to enable him, besides the official superintendence of the works carrying on at Antwerp and at Strasburg, to pursue the study of his favourite sciences; and upon occasion of a prize question, proposed by the Institute, he undertook the investigation of the extraordinary refraction of Iceland crystal, which the experiments of Dr Wollaston had lately shown to agree very accurately with the laws laid down by Huygens; and besides completely confirming all Dr Wollaston's results, he had the good fortune greatly to extend the Huygenian discovery of the peculiar modification of light produced by the action of such crystals, which Newton had distinguished by the name Polarity, and which Malus now found to be produced in a variety of circumstances, independently of the action of crystallized bodies. It seems natural to suppose that the investigation of the laws of the internal reflection of light, at the second surface of the crystals, must have led him to the discovery of the effects of oblique reflection in other circumstances; but according to Biot, there was more of accident in his actual progress; for he informs us that Malus had been looking through a piece of crystal at the image of the sun, reflected from the windows of the Luxembourg, to the house in the Rue d'Enfer, where he lived,

and that he was much surprised to find one of the double images disappear in a certain position of the crystal; although the next day, at a different hour, he could no longer observe the phenomenon, from the alteration of the angle of incidence.

Malus.

The merit of his discovery was soon acknowledged by his election as a Member of the Institute, as well as by the adjudication of a Biennial Medal from the Royal Society of London, on the foundation of Count Rumford. It has been thought creditable to the Royal Society to have conferred this distinction in the time of a war between the two countries; but if any credit were due for only doing justice conscientiously, it would attach, on this occasion, to those members of the Council, who saw their own optical speculations in great danger from the new mass of evidence, which appeared likely to overthrow them, at least in the public opinion, and who were still the most active in offering this tribute of applause to the more fortunate labours of a rival.

Nor was the remuneration of Malus confined to empty honours only; he obtained promotion, from the liberality of the French government, in his own profession AS A MILITARY MAN; and this not for services performed in the field, nor even in a difficult and dangerous expedition to unknown regions, but for experiments made with safety and tranquillity in his own closet. That government had not carried the refined principle of the division of labour so far, as to have resolved that all public encouragement should be limited to the precise department in which a public service had been performed; and a mark of distinction, which a gentleman could accept without degradation, was not deemed an incommensurate remuneration for a discovery in abstract science. Such a refinement, which has been practically introduced in our own matchless country, might appear, to a man who had a heart, something worse than sordid; he might fancy that a great nation, as well as a great individual, should treat its dependents, "not according to their deserts, but after its own honour and dignity;" if, however, a person in office happened to have any thing like a heart about him, the outcry of an indiscriminating opposition would soon teach him to silence its dictates.

1. Mr Malus's first publication appears to have been a paper *On an unknown branch of the Nile*, in the first volume of the *Décade Egyptienne*. 2. He presented to the Institute a mathematical *Traité d'optique*, before the completion of his experiments on double refraction; it was published in the *Mémoires présentés à l'Institut*, II. 4. Paris, 1810. 3. His more important discoveries were first made known in the second volume of the *Mémoires d'Arcueil*, 8. Paris, 1809; and again, 4. in the *Theory of double refraction*. *Mém. prés. à l'Inst.* II. a paper which obtained a prize the 2d January 1810. 5. In a short *Essay on the measurement of the refractive force of opaque bodies*, contained in the same volume, he employs the method, before made known by Dr Wollaston, for conducting the experiment, and computes the forces concerned upon the Newtonian hypothesis; applied, however, in a manner somewhat arbitrary to the circumstances of the problem. 6. *Remarks on some new optical phenomena*. *Mém. Inst. Sc.* 1810,

Malwah.

p. 105, Paris, 1814, read 11th March 1811. This paper is principally intended to prove that two portions of light are always polarised together in opposite directions, and that no part of the light concerned is destroyed, "as Dr Young had been inclined to suspect;" the author found that light transmitted obliquely through a number of parallel glasses at a proper angle, becomes at last completely polarised. Mr Arago had discovered a case which appeared to be an exception to the general law of the polarisation of transmitted light, but it was afterwards readily explained from the theory of the production of colours by interference, as applied to transmitted light. A letter, containing the substance of this paper, was published in Thomson's *Annals*, III. 257, Apr. 1814, on occasion of some discoveries of Dr Brewster, which had been supposed to be wholly new. 7. *On phenomena accompanying refraction and reflection*, p. 112; read 27th May, showing the universality of polarisation at a proper angle, and examining the effect of a metallic surface. 8. *On the axis of refraction of crystals*, p. 142; describing an apparatus for finding the properties of bodies with respect to polarised light, applied to the determination of the axis of crystals, and to the examination of the structure of organized bodies, which appear in general to have certain axes of polarisation, as well as those which are manifestly crystallized.

The zeal and energy of Malus supported him to the last, not only in the continuance of these interesting investigations, but also in his duties as an examiner at the *Ecole Polytechnique*. He died, 24th February 1812, universally regretted by the lovers of science in all countries, and deeply lamented by his colleagues, who said of him, as Newton did of Cotes, that if his life had been prolonged, we should at last "have known something" of the laws of nature.

(Delambre, *M. Inst.* 1816, P. XXVII. Biot in *Biographie Universelle*, XXVI. 8. Par. 1820.)

(T. v.)

MALWAH, an extensive province of Hindostan, situated principally between the 22d and 23d degrees of northern latitude. On the north it is bounded by the provinces of Ajmeer and Agra, on the east by Allahabad and Gundwanch, on the south by Khandeish and Berar, and on the west by Ajmeer and Gujerat, being in length about 250 miles, and in breadth 150. Till very recently, the whole of this territory was in the occupation of the Mahrattas, the capitals of Dowlet Row Sindca and Holkar being both in it, and within 30 miles of each other. Malwah is a very elevated region, as numerous rivers have their sources in it, and descend in every direction. The principal of these are the Narbudda, Chumbul, Sopra, and Cane. The land is, however, extremely fertile, the soil being in general a fine black mould, which produces cotton, opium, sugar, indigo, tobacco, and all the various grains of India, besides furnishing pasture for numerous herds of cattle, flocks of sheep, &c. Like Bengal and some other provinces, it has two harvests, the first or superior ending in April, the second or inferior in October. The tobacco, particularly that of the district of Bilsah, is highly esteem-

ed, and carried to all parts of the country. The other articles of its produce are sent to Gujerat, Broach, or into the eastern provinces, by the rivers which communicate with the Jumna. Bickermajeet, one of the most celebrated rajahs of Hindostan, of whom there is any authentic history, reigned over Malwah; he overran many of the other provinces, and compelled their princes to pay him tribute, and acknowledge him as their lord paramount. Such was his fame, that the 11ndoos have adopted his reign as one of their eras. It commenced 57 years before the birth of Christ. His capital was situated about a mile to the northward of Oujain, and bore the same name. This province was conquered by the Mahometans in the middle of the thirteenth century; but on the death of the emperor Balin, in 1286, the governor Dilavur Khan rebelled, and laid the foundation of an independent kingdom, which lasted upwards of 170 years. Their capital was Mundu, a very extensive city, situated in the hills, 20 miles south of Oujain. Malwah was subdued, and its capital taken by the Mogul emperor Homayon, in the year 1534, and remained annexed to the empire of Delhi till after the death of Aurungzebe in 1707, when it was invaded, and by degrees taken possession of by the Mahrattas; by whom it was divided into several portions among the chiefs, according to the gradual progress of their arms, which has caused such an intermixture of their territories, that it is extremely difficult to discriminate them. The ancient landholders, called Grassiah, still retain possession of some of the hill forts, and exact contributions from the adjoining districts; and a portion of the southern part of the province was till lately held by the Pindaree chiefs, whose incursions into the British dominions brought on the late Mahratta war.—*Edinburgh Gazetteer, or Geographical Dictionary.*

MARMONTEL (JEAN FRANÇOIS), a celebrated French writer, was born in 1723 at the picturesque village of Bort, in the Limousin, in a family little removed above the rank of peasantry. Like many other distinguished literary men of France, he owed the early part of his education to private charity and gratuitous public institutions. His parents destined him for trade; but his love for study induced him to assume the clerical habit, and to obtain admittance into the Academy of the Jesuits at Clermont. While there he procured a subsistence, by acting, during his leisure hours, as a private tutor to some of the more opulent students. He then went to Toulouse, where he delivered lectures in philosophy with considerable reputation, and gained an academical prize. His disappointment as to another prize opened for him a correspondence with Voltaire, which finally led to his departure from Toulouse for Paris, where he obtained the personal acquaintance of his illustrious correspondent, who at that time extended the most friendly encouragement to all young men possessed of any talents for poetry.

At the time of Marmontel's arrival in the capital, in 1745, the prizes proposed by the Academy opened up one of the shortest roads to literary distinction, and one eagerly pursued by those who were ambitious of celebrity. Marmontel, like many others,

Marmontel. commenced his career of letters by gaining a prize for a poem on a subject proposed by the French Academy—The glory of Louis XIV. perpetuated in his successor. But in that age the theatre afforded the most ample field for the acquisition of wealth and eminence. All talent was in a manner forced into that direction, and was often recompensed with extravagant liberality. In order to qualify himself for dramatic composition, he commenced an assiduous study of the best critical works on the subject, which he borrowed from Voltaire; he obtained free admission to the French theatre, which he regularly attended; and he frequented the *Procope* Coffee-house, which was then the tribunal of criticism, and the school for young poets to study the humour and taste of the public. His first tragedies, *Dionysius* and *Aristomenes*, obtained a reception sufficiently flattering for a youthful poet; but they did not keep their ground on the stage, and his succeeding ones, *Cleopatra*, the *Heracles*, and *Numitor*, had no success whatever. La Harpe, who was a great dramatic critic, condemns them all as bad, except the *Heracles*, which he calls a tolerable tragedy of the second rank. In fact, Marmontel does not appear to have been endowed with any talents for poetry, at least of the higher order, either in point of poetical conception or the mechanical construction of verse. It is also evident, from his *Reflexions sur la Tragedie*, published at the end of his *Aristomenes*, that he had formed, at least in the early period of his life, the most unfounded and paradoxical theories with regard to the rules of dramatic composition. Hence his plots have, for the most part, but little interest; his dialogue is full of puerile common-places; and his versification is cold and constrained. The plot of *Dionysius* hinges on the conspiracy of Dion against the Sicilian tyrant, and the love of the younger Dionysius (who, in defiance of all historical truth, is represented as a paragon of virtue) for the daughter of Dion, whose character is formed on the model of the heroines of Calpurne and Scuderi. The plots of *Aristomenes* and *Numitor* are, for the most part, of his own invention, and are both sufficiently extravagant. In the *Heracles* he has followed the well-known tragedy of *Euripides* as his guide. At his first interview with Voltaire, Marmontel had been assured by him, that by the stage he might in one day obtain glory and fortune, and that one successful piece would render him at the same moment rich and celebrated. The prediction was verified; and from the instant at which his first tragedy appeared, he, who had not money to pay the person who brought water to his lodgings, and who lived on credit with his baker and green-grocer, was at once plunged into all the bustling intrigue of the first literary circles, and into all the glare and dissipation of fashionable society. His time was occupied with rehearsals and parties of pleasure; he was

received as the favoured lover of the most celebrated actress of the age, Mademoiselle Clairon; and in another intrigue in which he engaged he became the rival of Marshal Saxe. In order to shun the resentment of so formidable a rival, he retired for some time to Passy, the country seat of the rich and sumptuous financier, Popliniere, who had married his mistress, and kept open house for all the idle and dissipated *litterateurs* of the age. By flattering the king in some occasional verses, which he wrote while residing here, he obtained the powerful patronage of Mad. de Pompadour, who procured for him the situation of Under Secretary of the Royal Buildings. This employment fixed his residence at Versailles for five years, which were passed wholly free from inquietude, and are often alluded to by him as the happiest period of his life. The duties of his situation occupied him two days in the week, and the remainder of his time was employed in contributing articles to the *Encyclopédie*, of which his friends D'Alembert and Diderot were the Editors. These articles, which contain many ingenious theories, mixed with strange paradoxes, were afterwards printed together, in alphabetical order, under the general title of *Elements de Litterature*.*

Having been engaged about the same time in writing on the subject of comedy, and searching into nature for the rules and means of the art, this study led him to examine if it were true, as was then often said, that all the great strokes of ridicule had been seized by Moliere and the dramatic poets who followed him. In running over the canvass of society, he perceived that, in the inexhaustible combinations of follies and extravagancies of all conditions of life, a man of genius might still find sufficient employment. He had even collected some observations to propose to young poets, when his friend M. de Boissi, who at the time conducted the *Mercur de France*, requested him to supply some pieces in prose, to insert in that literary Journal, from which Marmontel derived a considerable pension. It occurred to him to employ, in a tale, one of the touches of ridicule in his collection; and he chose, by way of essay, the absurd pretension of being loved merely for one's self. This was exhibited in the first of his *Moral Tales*, entitled *Alcibiade ou Le Moi*. The story was much admired, and was by some attributed to Montesquieu, and by others to Voltaire. Its success induced him to write other tales of a similar description; and thus commenced the *Contes Moraux*, which were subsequently collected and printed by themselves. Many of these tales, on which the fame of Marmontel principally if not solely rests, bear reference to the original idea with which they commenced, being for the most part intended to expose some absurdity or extravagance of character. Thus the second displays the folly of those who exert authority in order to bring a woman to reason; and he chose, for example of this, a sul-

* M. de Chapsal has extracted from the *Elements de Litterature* every thing that related to eloquence, and placed the remarks not in alphabetical order, but in that of the subject. This work, which is intended to form a manual of French rhetoric, is entitled *Principes d'Eloquence de Marmontel extraits de ses Elements de Litterature et mis en ordre*. Paris, 1809.

Marmontel. tan and his slave, as being placed in the two extremes of power and dependence. In most of them he has reached a very happy imitation of nature, in the manners and language; and it is only to be regretted that he has occasionally thrown a too glittering varnish over conceptions of the most beautiful simplicity. As lively pictures of French manners, both simple and fashionable, they are admitted to be unrivalled. The early part of the life of Marmontel was passed amid scenes of rural innocence, with a family which lodged in a cottage, and subsisted by the labour of their hands; the remainder of his days was spent in the most brilliant and refined society which Paris or the world afforded, exhibiting the most splendid union of literary talents, with all the polish of exalted rank, and the graces of female elegance. This enabled him to succeed in scenes and characters which were extremely remote, and, indeed, contrasted to each other—in the delineation of the innocent pleasures of the country, as well as the rivalships, whims, and levities, of gay or splendid life. *The Shepherdess of the Alps*, which has been the most popular of them all, and *Les deux Infantes*, are as distinguished for simple and touching pathos as the great proportion are for liveliness. The style is remarkable for facility, and the ease with which it inclines, in pursuing the course of events, to the ludicrous or pathetic.

After the death of M. de Boissi, Marmontel obtained the patent and sole management of the *Mercur*, of which he had long been the chief support. On receiving this appointment, he resigned that which he held at Versailles, and fixed his residence at Paris, in apartments assigned to him in the house of Mad. Geoffrin. He appears to have conducted the Journal of which he had charge with great ability and judgment. Few periodical works have appeared more diversified, more attractive, or more abundant in resources; and many who afterwards came to hold the highest rank in French literature were first introduced through it to the favour of the public. After he had conducted it, however, for two years, he became suspected of writing a satire against some powerful nobleman. He was, in consequence, shut up for a few days in the Bastille, and on his release, was deprived of his agreeable and lucrative situation. But this misfortune did not discourage his literary exertions. Soon after he had recovered his freedom, he translated into prose the *Pharsalia* of Lucan, of which he was a great admirer. He also added to it a supplement, in which he details the events of Cæsar's war in Africa, and concludes with his last campaign in Spain. The French have at all times been great dealers in prose translations of the Classics. But though the shape in which Marmontel exhibited the *Pharsalia* can never convey an adequate idea of the original, his work is more agreeable to read than the turgid poetical version of Brebeuf, by which it was preceded.

About the same time at which he completed the translation of the *Pharsalia*, he published his *Poétique Française*, containing observations extracted from the various articles which he had furnished for the *Encyclopédie*. It is divided into two parts, the first expounding the elementary principles of

poetry, and the second applying them to its different sorts. Marmontel.

Being about this period seized with a disorder in the chest, which had proved fatal to both his parents, he resolved to devote his remaining days to the composition of a Romance, or fiction of the higher order. The subject he chose was *Belisarius*, suggested to him by a print he possessed from the celebrated picture of Vandyck. The fact on which his tale is founded was rather a popular tradition and opinion than a historical truth. But the belief had so universally prevailed, and the idea of a blind old man reduced to beggary had been so closely associated with the name of Belisarius, that it possessed all the advantages essential for the purposes of historical romance. In other particulars, the author relied on the faith of history, and Procopius chiefly was his guide. On its first appearance, in 1767, *Belisaire* attracted universal attention. The first seven chapters, describing the journey of the old blind hero to the village where his family resided—his arrival there, and the visit paid to him by Justinian, in his humble habitation, are possessed of an interest almost dramatic, and are composed in a higher tone of eloquence than any thing else which he has written. But those which follow are almost entirely destitute of incident, and are just so many separate lectures on different branches of government and politics delivered by Belisarius to Justinian. In the course of these dissertations, there are evidently many references to political incidents, and the system of French politics pursued in the middle of the seventeenth century. The last chapter, on religious toleration, involved the author in a dispute with the Sorbonne, who published a censure on it, which was opposed by the arguments of Turgot, and by the epigrams and squibs of Voltaire.

Though *Belisarius* cost its author many sleepless nights, he recovered during its composition from the disorder which had excited him to the undertaking, and he sometime after produced his *Incas of Peru*, dedicated to Gustavus King of Sweden. Irritated as he was by the recent anathemas of the Sorbonne, his great object in this new romance was to show, that all the evils inflicted by the Spaniards on the Indians had their origin in that fanaticism which he was desirous to bring into still deeper detestation. In Fernando de Luquez and Vincentio Requielme he has given a sort of personification of fanaticism in its most hideous form, and has contrasted their characters with that of Las Casas, which is intended as a model of the exalted piety and tempered zeal most becoming in a Christian. In the history on which this romance is founded, Las Casas had given a tremendous picture of the atrocities committed by the Spaniards in Peru, and of the sufferings of its inefficient inhabitants. The pencil of Marmontel had scarcely sufficient strength to paint the determined courage, rapacity, debauchery, and remorseless cruelty of the soldiery let loose on the Indians, nor the desperate characters of the adventurers at their head, who knew no law but the sword, and whose sole object was plunder. In painting Indian scenes of innocence, tranquillity, and peace, he has been more

Marmontel. fortunate. But he has unluckily abandoned the simplicity, which charmed so much in his *Moral Tales*, for a tone too highly rhetorical; and there is a want of unity of interest from the multiplicity of episodes. The longest is that of the Conquest of Mexico, related to the Inca by some refugees from that country, and who had come all the way to Quito, apparently for no other purpose than to tell their long story.

In 1763, Marmontel had been admitted, though after considerable opposition, to the much envied place of a member of the French Academy, and, in 1783, he succeeded D'Alembert as its perpetual secretary. The situation of Historiographer of France, and the Chair of History in the Lyceum, which he successively obtained, fully indemnified him for the loss of the *Mercur*. He was in the full enjoyment of affluent circumstances, domestic felicity, and literary reputation, when the French Revolution suddenly changed the scene. During its alarming progress he led a retired life, and though reduced to indigent circumstances, remained secure amid all the violent events of the period. In 1797, he was chosen a deputy to the National Assembly by the department of Eure, but died soon afterwards, of an apoplectic attack, at his cottage near Abbeville.

Several of his pieces were published after his death. The *Nouveaux Contes Moraux*, which were inserted in the *Mercur*, had been extracted from that journal, and translated into English soon after their first appearance: but they were not printed apart in their original language till after the demise of the author. This second series is inferior in delicacy, grace, and beauty of style, to the former; but the scope and tendency of the stories is more strictly moral. On account of his situation as Historiographer of France, Marmontel had thought it a duty incumbent on him to write some historical work. The period he chose was the Regency of the Duke of Orleans, which he commenced in 1784; but though he completed it four years afterwards, it was not given to the public during his life. This work is not such, either in point of accuracy of facts, or enlightened general views, as might have been expected from the time occupied in its composition, the materials which his situation opened up to him, or the pompous account which he himself gives of his access to information: "All the great men," says he, "of the age opened to me the repositories which contained documents on my subject. The Count de Broglie initiated me into the mysteries of his most secret negotiations, and Contades traced to me, with his own hand, the plan of his campaigns, and particularly of the battle of Minden." The most interesting part is the last chapter, containing the relation of some particular incidents which occurred during the regency, as the plague at Marseilles, and the visit of the Czar Peter to France.

The *Posthumous Memoirs* of Marmontel, drawn up in his declining years for the instruction of his children, and edited in 1804, from a MS. in his own hand-writing, are among the most amusing volumes of the description ever presented to the public. They commence with the author's earliest youth: the portion which comprehends this period of his life is

written in the happiest style of his *Moral Tales*, and contains many interesting anecdotes of humble innocence, many animated sketches of domestic happiness, and many agreeable traits of village society. In the succeeding part, the portraits of the most distinguished characters, in the most brilliant age of France, are delineated with so much life, discrimination, and delicacy, and every thing is sketched with a colouring so light and aerial, that the whole representation is exquisite. There is scarcely a single person of note in France whose likeness is not exhibited in this vast gallery,—the pictures of Voltaire, D'Alembert, Marivaux, Thomas, St Lambert, and Helvetius, are all excellent. The society which Marmontel frequented was probably the most refined and brilliant that had ever assembled together; but there was evidently a restraint, a desire of exhibition, and want of ease in its intercourse. "Every guest," says Marmontel, "arrived ready to play his part; in Marivaux, impatience to give proof of acuteness and sagacity was visibly betrayed; Montesquieu, with more calm, waited till the ball came to him, but he expected it; Helvetius, attentive and discreet, sat collecting for a future day." Literary fame was enjoyed in France in its greatest extent, but also in its greatest anxiety. Of all the others, Voltaire had gained the most brilliant literary success; yet of him Marmontel remarks, that his glory was too dearly paid by the tribulations to which it had exposed him. It had been said by Mad. Genlis, that Marmontel, in his *Moral Tales*, showed gross ignorance of the French manners and character, in representing the higher classes, particularly of females, as so voluptuous, and in many cases abandoned; but the *Memoirs*, if they record the truth, unhappily confirm his representations. When so much amusement is derived from his minute descriptions it is perhaps hypercritical to remark, that some petty circumstances, of no general interest, and which might have been better thrown into the back-ground, are brought too much out on the canvass, and are drawn in disproportioned magnitude. But for these details, he states as his apology, that it is for his children he writes the history of his life, and that those things which may appear too minute to strangers, will prove interesting and useful to them. The concluding volume, containing a sketch of the first events of the Revolution, is confused and imperfect. Its incidents were too gigantic for the grasp of his mind, and he appears to have been dizzied and stupified by the rapid whirl and total subversion which he witnessed.

An author by profession, the literary character of Marmontel may be fully appreciated from his various and numerous productions. Though he admits that, while he has given the portrait of others at full length in his *Memoirs*, he has only painted himself in profile; yet from them his private character may be correctly enough estimated. On a review of these, it has been remarked, "That without great passions, or great talents, he seems to have had a lively imagination, a pliant and cheerful disposition, and a delicacy of taste and discrimination, of still greater value in the society which fixed his reputation. Although good tempered and social, he

Marmontel seems to have been, in a good measure, without heart or affection; or rather the dissipated and sensual life to which he devoted himself after his removal to Paris, appears to have obstructed in him the growth of all generous and exalted feeling. In society he was joyous and easy; gay, without affecting to dazzle, and ingenious, without intolerance or fastidiousness. (M.)

Maskelyne.

MASKELYNE (NEVIL), a most industrious and accurate astronomer, born in London, 6th October 1732, was the son of Edmund Maskelyne, Esq. a gentleman of respectable family of Purton in Wiltshire.

He was sent at the age of nine to Westminster School, and continued to apply with diligence to the usual pursuits of that place, until the occurrence of the great solar eclipse of 1748, which made a strong impression on his mind, and which was the immediate cause of his directing his attention to astronomy, and of his beginning the study of the mathematics with great ardour, as subservient to that of astronomy. It is remarkable, that the same eclipse is said to have made an astronomer of Lalande, who was only three months older than Maskelyne. He soon after entered as a member of Catherine Hall, Cambridge, but shortly removed to Trinity. He took a degree as Bachelor of Arts with great credit in 1754, and proceeded regularly afterwards through the succeeding stages of academical rank in divinity. He was ordained in 1755 to a curacy at Barnet, and the next year obtained a fellowship at Trinity. In 1758 he was elected a Fellow of the Royal Society, having previously become intimate with Dr Bradley, and having determined to make astronomy the principal pursuit of his life, feeling its perfect compatibility with an enlightened devotion to the duties of his own profession.

In 1761 he was engaged by the Royal Society to undertake a voyage to St Helena, in order to observe the transit of Venus. He remained ten months in the island, but the weather prevented his observing the transit to advantage, and the faulty attachment of the plumb-line of his quadrant, which was of the construction then usually employed, rendered his observations on the stars less conclusive with respect to annual parallax than he had expected. His voyage was, however, of great use to navigation, by promoting the introduction of lunar observations for ascertaining the longitude; and he taught the officers of the ship which conveyed him the proper use of the instruments, and the mode of making the computations.

He performed a second voyage, in 1763, to the island of Barbadoes, in order to determine the rates of Harrison's watches, and to make experiments with Irwin's marine chair, on board of the Princess Louisa, Admiral Tyrrel, acting at the same time as chaplain to the ship. The chair he found of very little use for observing the eclipses of Jupiter's satellites, and the maker of the chronometers was not satisfied with his report of their performance; fancying that he was too partial to the exclusive employment of lunar observations for determining the longitude. The liberality of the British Government, however, bestowed on Harrison the whole reward that he claimed; and Maskelyne, having been appointed to the situation of

Astronomer Royal, and having thus become a member of the Board of Longitude, was extremely active in obtaining a few thousand pounds for the family of Professor Mayer, who had computed lunar tables, and a compliment of L.300 only for Euler, whose theorems had been employed in the investigation.

The merits of Mayer's tables having been fully established, the Board of Longitude was induced to promote their application to practical purposes, by the annual publication of the *Nautical Almanack*, which was arranged and conducted entirely under Maskelyne's direction for the remainder of his life. He was also actively employed, without any other motive than the love of science and of his country, in almost every decision which was required of the Board of Longitude; and he had to give his opinion of the merits of an infinite number of fruitless projects which were continually submitted to his judgment. He must of course have made many enemies among the weak and illiberal; but the universal impartiality, and the general accuracy of his determinations, were acknowledged by all candid persons; and it must be admitted that the longitudinal speculators of Great Britain do in general submit to discouraging remarks from persons in authority with wonderful fortitude, and with great personal civility.

During the forty-seven years that he held the situation of Astronomer Royal, he acquired the respect of all Europe by the diligence and accuracy of his observations, which he never neglected to conduct in person whenever it was in his power, and he required only one assistant. The French had a handsome building to amuse the public by its exterior magnificence, but the establishment of the observers was never arranged in so methodical a manner as that of the English National Observatory, and the fruits of their labours were never systematically made public; the attempt which was once made by Lemonnier, in his *Histoire Céleste*, having been interrupted and discontinued. Dr Maskelyne, on the other hand, obtained leave from the British Government to have his observations printed at the public expence, under the direction of the Royal Society, who are the legal visitors of the Observatory, appointed by the King's sign manual. The early observations of Flamsteed and Bradley were considered as private property: Flamsteed published his own, and Bradley's were very liberally bought of his family, and afterwards printed by the University of Oxford, who are still as liberal in bestowing them where they are likely to be employed for the benefit of science. Flamsteed was the Astronomer Royal from 1690 to 1720; then Halley to 1750; Bradley to 1762, and Bliss to 1765, when Maskelyne was appointed. He took his doctor's degree in 1777.

He made several improvements in the arrangement and employment of the instruments, particularly by enlarging the slits through which the light was admitted; by making the eye-glass of his transit telescope moveable to the place of each of the wires of the micrometer; and above all, by marking the time to tenths of a second, which had never been attempted before; but which he found it practicable to effect with surprising accuracy, as the comparison of the

Maskelyne

Maskelyne's observations at the different wires sufficiently demonstrated.

The object of his expedition to Shehallien is well known. Bouguer had made an unsuccessful attempt to measure the attraction of a mountain in South America, and had been obliged to conclude that the mountain was hollow, in consequence of the eruption of a volcano, the attraction being too little sensible. Dr Maskelyne's results, on the other hand, as computed by Dr Hutton, made the mountain more dense than could well have been expected; but those who are acquainted with the difficulty of executing astronomical measurements without an error of a single second of space, will be ready to allow that the deviation of 5" or 6", attributed to the effect of the mountain, is liable to a much greater proportional uncertainty than the results obtained by Mr Cavendish with the apparatus invented by Mr Michell. (See CAVENDISH.) The geodetical operations which were soon afterwards performed with his concurrence and assistance, for determining the relative situations of Greenwich and Paris, were equally creditable to the English artists who constructed the instruments, and to the astronomers and geographers who made the observations with them; and they excelled, even by the confession of their rivals, every thing that had ever been effected in former measurements of the same kind.

As no man had done more for practical astronomy than Dr Maskelyne, so there was none whose merits were more justly appreciated. He made every astronomer his friend, as well by his personal kindness, as by his professional labours; and he obtained the rare distinction of being made one of the eight foreign associates of the Parisian Academy of Sciences. His example and encouragement contributed to the establishment of several private observatories, which must always be, if not immediately, at least remotely, beneficial to astronomy, as tending to promote the improvement of instruments, and of the methods of employing them.

He was modest, and somewhat timid, in receiving the visits of strangers; but his usual conversation was cheerful, and often playful, with a fondness for point, and for classical allusion. He inherited a good paternal property, and he obtained considerable preferment from his college; he also married, somewhat late in life, the sister and co-heiress of Lady Booth of Northamptonshire. His sister was the wife of Robert Lord Clive, and the mother of the present Earl of Powis. He died the 9th of February 1811, in his 79th year, leaving a widow and an only daughter.

1. Dr Maskelyne's first communication to the Royal Society is *A proposal for discovering the annual parallax of Sirius*. *Phil. Trans.* L.I. 1760. p. 889. It is founded on Lacaille's observations, made at the Cape of Good Hope, which appeared to indicate a maximum amounting to 8". 2. *A theorem for spherical aberration*. LII. 1761. p. 17. Dated from the Prince Henry, St Helen's Roads: the calculation is adapted to the object-glasses of achromatic telescopes. 3. The next article, p. 21, is a letter from Lacaille, recommending him to make observations at St Helena on the lunar parallax, and to remain some

time in the island for that purpose; promising, on his own part, to make corresponding observations. It is followed by a *Letter from Maskelyne*, proposing some additional joint observations. 4. *Observation of the transit of 1761*, p. 196. The sun was lower than had been expected, and the instant of contact uncertain, from a tremulous motion in the apparent discs. 5. *Observations on a clock of Shelton*, 1762, p. 434. Giving the proportion of .99754 to 1 for the comparative force of gravity at Greenwich and at St Helena. 6. *A letter on the mode of observing and computing lunar distances*, p. 558. Dated from St Helena: the first demonstration of the practicability and utility of the method. He found the error of observation not to exceed half a degree of longitude, an error which was very strangely suffered to remain as a fair allowance for the uncertainty of observation, in the acts for encouraging the perfection of the lunar tables, only very lately repealed. 7. *On the tides at St Helena*, p. 586. Observations made in a harbour, for about two months. 8. *Note to Lalande*, p. 607. On lunar distances and occultations. 9. *Rules for correcting lunar distances*. *Phil. Trans.* 1764, p. 263. A demonstration of the rules before published in the *Transactions* and in the *British Mariner's Guide*. 10. *Remarks on the equation of time*, p. 336. Correcting a mistake of Lacaille, and an inadvertence of Lalande, and giving a formula, which, though not geometrically perfect, is abundantly accurate for all practical purposes. 11. *Astronomical observations made at St Helena*, p. 348. The observations for determining the lunar parallax were too few to afford a satisfactory result. The author suggests, that the figure of the earth might be ascertained by repeated and comparative observations of the apparent distance of the moon from neighbouring stars. 12. *Observations made at Barbadoes*, p. 189. Especially on Jupiter's satellites. 13. *Introduction to two papers of Mr Smeaton*. LVIII. 1768, p. 154. The one on the menstrual parallax, the other on observing stars out of the meridian. 14. *Introduction to the observations of Mason and Dixon*, p. 270. 15. *Conclusion respecting the length of a degree*, p. 323, 325. Mr Charles Mason had been sent with Mr Dixon to observe the transit of 1761, at Bencoolen, but their voyage was interrupted by accidental circumstances, and they made their observations at the Cape of Good Hope, with tolerable success. They then proceeded to join Maskelyne at St Helena, and to assist in his operations there. They were afterwards engaged by Lord Baltimore and Mr Penn, to determine the boundaries between Maryland and Pennsylvania; and having completed their survey, they suggested to the Council of the Royal Society the eligibility of measuring a degree in the country bordering on the Delaware and Chesapeake. Their proposals were readily accepted, and the results of their measurement are here recorded. Dr Maskelyne afterwards employed Mason, in his operations on Shehallien, and in computing Bradley's observations, and in improving Mayer's tables, by a comparison with them; but he was so fearful of admitting any empirical corrections, not founded on the most general principles, that he would not allow some of the equations, discovered by Mason, to be intro-

Maskelyne, deduced into the computation of the *Nautical Almanac*, until Laplace had proved their dependance on the theory of gravity. Lalande tells us, that Mason was dissatisfied because he did not receive a public reward for the success of his labours; but he was, in fact, little more than the agent of Maskelyne, and of the Board of Longitude; and he was fairly repaid for the time and labour which his computations had required. Delambre says, that he died in Pennsylvania in 1787. Dixon is said to have been born in a coal mine; and to have died at Durham in 1777. 15. *Postscript respecting French and English measures*, p. 325. The result of this comparison agrees admirably well with the later measurement of Pictet, Prony, and Captain Kater. 16. *Observation of the transit of 1769, made at the Royal Observatory*, p. 355. 17. *Eclipses and occultations*, 1769, p. 399, chiefly for the longitude of Glasgow. 18. *On the use of Dolland's micrometer*, 1771, p. 536. On the application of the divided object-glass micrometer to determining differences of right ascension and of declination, especially in the case of transits. A part of the instructions sent with the observers to the South Seas. 19. *On the adjustment of Hadley's quadrant*, 1772, p. 99. Especially for the back observation; and to insure the parallelism of the glasses. 20. *Deluc's rule for measuring heights*, 1774, p. 158. Adapted to English measures, and rendered somewhat more convenient. 21. *Observations at Greenwich and in America compared*, p. 184, 190. 22. *Proposal for measuring the attraction of a hill*, 1775, p. 495. Read in 1772. 23. *Observations made on Shehallien*, p. 500. A paper which obtained its author the honour of a Copleian medal. Mason had been sent to examine the hills of Scotland, and had recommended Shehallien; the funds were supplied by the remainder of the royal grant for observing the transit of Venus. Mr Reuben Burrow and Mr Menzies were principally employed in assisting the Astronomer Royal in his observations and surveys; and Dr Hutton afterwards made the necessary computations for determining the attraction of the mountain. 24. *Description of a prismatic micrometer*, 1777, p. 799. Consisting of one or more prisms sliding in the axis of the telescope; and resembling in its operation that of Rochon, which has in great measure superseded it. 25. *On the longitude of Cork*, 1779, p. 179. Observations for correcting the computed times of the eclipses of Jupiter's satellites. 26. *On the comet expected in 1789*, *Ph. Tr.* 1786, p. 426. Supposing those of 1532 and 1661 to be the same. (See MECHAM.) 27. *On the latitude and longitude of Greenwich*, 1787, p. 151. With Cassini's memoir on its uncertainty, which he states as amounting to 11" in longitude, and 15" in latitude. Dr Maskelyne, however, shows that it is confined within much narrower limits, though he approves of the object of the memoir in promoting a survey. 28. *On a difficulty in the theory of vision*, 1789, p. 256. This paper sufficiently proves, that Euler was mistaken in thinking the eye achromatic; and that any appearance of colour which it could produce, according to the common laws of refraction, would be imperceptible in ordinary circumstances. But that there are circumstances, under which such appearances may

be observed, has been more lately shown by Dr Young and Dr Wollaston. 29. *Account of an appearance of light on the dark part of the moon*, 1793, p. 429. Seen by Mr Wilkins, and by a servant of Sir George Booth, and supposed to have arisen from a volcano. 30. *Observations of the comet of 1793*, *Ph. Tr.* 1794, p. 55. Discovered by the Rev. E. Gregory of Langar, in Nottinghamshire.

31. The earliest of Maskelyne's separate publications was his *British mariner's guide*, 4. Lond. 1763. A small volume, which has become scarce, having been superseded by later works.

32. *The nautical almanac and astronomical ephemeris* for 1767 appeared in 1766; and the publication has been regularly continued upon the same plan to the present time, by the computers and comparers whom Dr Maskelyne had trained by his instruction and example. His successor in the Observatory, though admirably qualified to equal, and perhaps to excel him in the practical department, had it not in his power to devote so much of his attention to the publication, as Dr Maskelyne's paternal affection for a child of his own had induced him to bestow on it; and the Board of Longitude was very liberally furnished by the present ministry, with the means of obtaining some further assistance to supply his place.

33. *Tables requisite to be used with the nautical almanac*, 8. Lond. 1766, 1783, 1802. Now partly superseded by Professor Lax's new edition.

34. The volume of *Selections*, from the additions that have been occasionally made to the *Nautical almanac*, 8. Lond. 1812, contains several papers of Dr Maskelyne. For example, *Instructions relating to the transit of Venus in 1769*, N. A. 1769. *Elements of lunar tables*, and *Remarks on Hadley's quadrant*, N. A. 1774. *Advertisement of the comet expected in 1788*, N. A. 1791. *On the disappearance of Saturn's ring in 1780*, N. A. 1791.

35. The *Astronomical observations made at Greenwich*, from 1765 to 1811, were published annually in folio; making three volumes, and part of a fourth Lond. 1774. . . . They are allowed to constitute the most perfect body of astronomy in detail that was ever presented to the public. The first volume contains a variety of useful tables, accompanying the observations for 1772; and principally serving for the correction of the places of the stars, and for facilitating the solution of other astronomical problems. Many of them have been reprinted in Vince's *Astronomy*; but, in some cases, without the necessary explanations.

[*(Kelly in) Rees's Cyclopaedia*. ART. MASKELYNE. Chalmers, *Biographical Dictionary*, XXI. 8. Lond. 1815. Delambre, *Mém. Inst. Sc.* 1811, H. lix.; and in *Biographie Universelle*, XXVII. 8. Par. 1820.]

(N. A.)

MASON (CHARLES), an able astronomer. See MASKELYNE.

MAURITIUS. We have little to add to the account of this island contained in the *Encyclopaedia*, except what is derived from the accounts given of it by Captain Flinders, and the official documents from the public offices since it has become a British possession.

Mauritius.

The expedition for its conquest was planned in India, and executed with considerable talent and arrangement. The forces were collected from various parts of India in the middle of the year 1810; they rendezvoused at the island of Rodriguez in October of that year, and landed on the eastern side of Mauritius the latter end of December, without any opposition. The capital is strongly defended on the sea side, but towards the land its defences are weak, from their great extension. When the troops were landed they were not opposed on their march by any corps of the enemy, and had only the asperities of a mountainous country to overcome. On reaching the capital, in which all the military strength of the colony was concentrated, and where a respectable defence was expected, preparations were made for storming it, which were rendered needless by a flag of truce being sent. A capitulation followed, and the surrender of the capital, the forts, and the whole island, was executed on the 4th January 1811.

By the peace of Paris, in 1814, the full and perpetual sovereignty of this valuable settlement was ceded to Great Britain, and has continued under the colonial system of his Majesty's other distant possessions, independently of the control of the East India Company.

The extent of this island is about 31 leagues in circumference, being 11 leagues in length, and 7 in breadth. Its surface contains 432,600 British statute acres. The north-west part is level, but the north-east is covered with mountains of various heights, from 2700 to 3150 feet. The scenery in the mountainous parts is highly picturesque, exhibiting lofty rocks, deep ravines, and impetuous cascades. The south-west part is an extended mountain plain, whose mean height above the level of the sea is about 1500 feet, and where a more mild and temperate climate is enjoyed, than in the capital or the other parts on the sea-coast. This elevated plain (Wilhem's Plain) occupies a considerable portion of the interior of the island, extending from near the sea on its northern extremity, to near Port Bourbon on the south-east coast, and its surface is about 90 square miles. On this plain are several lakes, from which issue the numerous rivers and rivulets that water the island.

One of the lakes, the Mareaux Vacouvas, is one of the natural curiosities of the country. It is an irregular piece of fresh water, about one mile in length, surrounded with many hundred acres of swampy land, through which it receives several streams from the neighbouring hills. It is said to be from 20 to 25 fathoms deep, is well stocked with eels, prawns, and a small red fish called *danne-cere*, brought originally from China. The eels and prawns are indigenous, and attain a large size; the latter are sometimes found six inches long without the beard, and the eels are commonly from six to twenty pounds weight, and are said occasionally to attain the weight of eighty pounds; they are delicious food, and the larger they are the more highly is their flavour esteemed. Its form has more affinity to the conger than to the fresh water eel, and nearly resembles the species caught in the small streams on

Mauritius.

Norfolk Island, in the Pacific Ocean. About six miles from Vacouvas lake, another lake, called the Grand Basin, greatly exceeds it in depth. This basin is nearly half a mile in diameter, of a circular form, and said to be more than eighty fathoms in depth. The banks are rocky, and have the appearance of a mound, thrown up to prevent the waters from overflowing, and the surrounding land, especially to the southward, being considerably lower, gives the basin the appearance of a cauldron, about two-thirds filled. No perceptible stream runs into it, but several issue from it through hollow parts of the rocky bank. These, by various additions, form three rivers, that run into the sea on the south and south-east sides of the island. No great difference takes place in the level of the water, except after heavy rains, when the supply, which must come chiefly from the springs in the bottom, so far exceeds the quantity discharged as to raise it sometimes as much as six feet. The elevated bank round this basin consists of stones loosely thrown together, which, though porous, are heavy and hard, of a dark grey colour, and contain numerous specks, which appear to be feld-spath, with some particles of mica and olivine: it is more or less ferruginous, and in some parts appears to run in the manner of lava. It is natural to infer, that, if the whole island does not owe its existence to subterraneous fire, it has been subject to volcanic eruptions, and that the Grand Basin is the remains of one of them.

The climate, on these elevated plains, is remarkably moist. A day seldom passes in the whole year without rain upon them, whilst on the low grounds very little falls, except from December to March. This moisture creates an abundance of vegetation, and would render the middle parts of the island extremely fertile, if the soil were not washed down by the violent rains into the low lands, and into the sea as soon as it is formed. The little soil that does accumulate is good, and increases, though slowly, for the decayed wood adds something to its quantity every year, whilst the trunks and roots of the trees save a part from being washed away. A plantation covered with loose rocks is found to retain its fertility the longest, apparently from the stones preserving the vegetable mould from being washed away. The produce of the different districts in Mauritius varies according to their elevation and climate. The chief food for the black population, consisting of maize, rice, manioc, and sweet potatoes, is raised with great facility in different parts; but owing to the want of roads, and the scarcity of beasts of burden, which renders it necessary to employ human labour in conveying productions to market, the prices vary very much in different parts. The articles cultivated for exportation are by no means profitable, as the planters of the neighbouring island of Bourbon can raise coffee and cotton much cheaper, and of better qualities. The spices of Ceylon have been attempted to be cultivated, but hitherto with little success. There are few indigenous fruits, and none abundant, except the plum which grows on the ebony tree; but the banana, the pine apple, the melon, the jack, the orange, the lemon, the Avogada pear, the mangosteen, and the

Mauritius. cocoa tree, have been introduced, and propagated with various success. The most valuable of its trees was the ebony, the heart of whose timber is usually sold by weight. It is a slender and lofty tree, having only a few branches near the top. It produces clusters of an oblong fruit the size of a plum, full of a viscous sweetish juice of rather an agreeable taste. The usual circumference of a good tree is from three to four feet; when the exterior wood is clipped away, a black log remains of about six inches in diameter, and from twelve to fifteen feet long, whose weight usually exceeds three hundred pounds. It is principally exported to the China market. At one time, the planters were induced to cut those trees that had not attained a sufficient size, and as its growth is very slow, there is not the same abundance of them as was formerly found on the island.

Mauritius seems more exposed to the visitation of hurricanes than any other spot on the globe. These usually occur between the months of December and May. Their force is irresistible, and in their course they lay flat the productions of the fields, dissipate most of the marks of industry, scatter the houses, and compel the ships in the roads to abandon their anchorage and fly to the open sea for safety. The only town in the island is Port Louis; the rest of the inhabitants live in scattered plantations, and though sometimes six or eight houses may be found contiguous, yet generally the nearest neighbour is a mile distant. The entrance to the harbour of Port Louis is defended by strong forts on the island of Tonneliers on one side, and by Fort Blane on a peninsula opposite to it. From these points to the city the channel is narrow, and when the buoys are removed, difficult to pass. Near the city the anchorage is good, if care be taken to avoid the numerous wrecks that are at the bottom, with a depth of water varying from six to fourteen fathoms. The entrance to the harbour is nearly a course from north-north-east to south-south-west, by which all the shoals are avoided. The tide rises ordinarily about two feet, but at the equinoxes about three feet. The time of high water, at new and full moon, is noon. The only other harbour, called Grand Port, on the south-east side of the island, is but little frequented. It has no town near it, and though, from the prevalence of south-east winds, it is easy of access, from the same cause it is difficult of departure. The Dutch, when in possession of this island, erected a new town near it, but it is gone to decay, and only the vestiges of the buildings are now visible.

The commerce of the island, either with Europe or India, is by no means extensive. The whole of the necessaries of life are supplied to the great mass of the inhabitants from their own cultivation, and the European articles that are wanted for the higher classes require but small importations. No accurate accounts of the imports and exports are returned to any of the offices of government in Great Britain. We have no accounts of the whole population; and the hearsay reports of travellers differ so much as to merit little confidence. The only authentic document is the return of slaves to

the colonial register office for slaves. The latest return is that of 1817, when their numbers were 85,423. The free inhabitants are not supposed to be more than as three to two of the slaves; and the whole number of inhabitants may be about 200,000.

(w. w.)

MAYO, a maritime county in Ireland, having the Atlantic Ocean on the north and west, and the counties of Galway, Roscommon, and Sligo, on the south and east. Castlebar, the principal town, is in north latitude 53° 50', west longitude 9° 8'. It contains 2339 square miles, or 1,496,960 English acres; and is divided into nine baronies, and 62 parishes. Mayo is situated in the province of Connaught; and the see of Killala, whose bishop resides at the town of that name in this county, is within the archbishopric of Tuam.

A large proportion of the surface of Mayo consists of mountains, bogs, and lakes. More than half the county, particularly on the west and north-west, may be described as mountainous; and much of this tract is covered with heath, though the sides of many of the hills are green, and the vallies in some places remarkably fertile. Croagh Patrick is 2661 feet high, and Mount Nephin 2630 feet. On the west coast, which is exceedingly irregular, are Broad Haven, Blacksod Bay, and Newport, or Clew Bay, arms of the sea: and a number of small islands, of which Clare, at the entrance to Newport Bay, is the most considerable; and on the north is the bay of Killala. From Castlebar to the inland boundary on the east and south, the country is in general less rugged, and contains a great number of small towns and villages. There is very little full grown wood in Mayo, and the greater part is without plantations. With the exception of Lord Sligo's grounds, on the south-west, and the demesnes of a few other proprietors, the country is naked, and exposed to every storm.

The principal lakes are Lough Carra, Lough Mask, the Lake of Rahins, and Lough Conn; the latter is about nine Irish miles long, and four broad. The rivers are, the Robe and Black river, the Erriff, the Deel, and the Moy, with several smaller streams. The Moy is navigable for boats of 50 tons a few miles from its mouth.

Iron-ore, slate, ochre, manganese, sandstone, and pipe and brick clays, are plentiful. Iron works were formerly carried on to some extent, but, as in many other parts of Ireland, have been discontinued, from the want of fuel. Near Westport there is a quarry of slates of a quality equal to any brought from England. Here also are great rocks of the *Petrosilex semilucidus*, similar to that which is used in the English potteries.

Mayo is divided into estates worth from L. 7000 to L. 20,000 a year; but their extent, owing to their containing a great proportion of waste land, is still greater than in the ratio of their value. If a qualification of L. 1000 *per annum* were required, two grand juries might be formed in this county.

Agriculture is in a very backward state. The plough, commonly drawn by four horses abreast, is of the worst description, and the harrows are often furnished with tines of wood, instead of iron. It is

Mauritius
Mayo.

Situation.

Extent.

Surface

Estates.

Agriculture.

still the practice, in the mountain districts, to yoke the horses by the tail. But, in some of the baronies, the plough is seldom or never employed at all, the tillage being performed by the spade, and in others they use the spade in cultivating potatoes, and the plough only for corn. Yet potatoes, oats, and on the sea coast, barley, are sown to a considerable extent, and also flax. Wheat is cultivated only in particular spots, and chiefly by proprietors, a few of whom have also introduced turnips, pease, beans, rape, and cabbage. There is some excellent grazing land for cattle in the barony of Trawley, and good sheep pastures in Kilmain. Some graziers hold 3000 Irish acres. The English long-horned cattle, which were imported by the principal proprietors, have greatly improved the native breed.

Farms.

The size of farms varies with the nature of the soil and surface, but, though several hundred acres are sometimes let out in one farm, yet, as the farms are commonly held in partnership, the space allotted to each tenant is generally only a few acres. As each of them keeps a horse, it is computed that there is one for every ten or twelve Irish acres. The leases are for different periods, 15 years, 21 years, and one, two, and sometimes three lives, or 31 years.

Town

Dr Macparlan, the author of the *Statistical Survey of Mayo*, enumerates forty-six towns at which fairs are held, but most of them are only small villages. The principal towns are Castlebar, Westport, Ballina, Killala, Clare, Ballinrobe, and Newport. None of them are of such importance as to be represented in Parliament. The assizes are held alternately at Castlebar and Ballinrobe.

Wage and
Prices

The habitations of the labourers, or cottiers, are in general very wretched, and shared by them with their cow and pig. The cost of a cabin is from L.3 to L.5. The fuel is almost universally bog-turf. Potatoes, oatmeal, milk, and herrings, are, with few exceptions, their only articles of food, the lower classes seldom tasting meat. They are clothed in their domestic manufactures, frizes, druggets, flannels, and linen; a man's complete suit, including hat, shirt, stockings, and shoes, with a great coat, costs about L.2, 17s. 3d. Irish currency. The subsistence of a family of six is said to be worth from L.1 to L.20. The common price of labour, in 1802, was 8d. a-day; potatoes, 1s. 1d. per cwt.; beef, 3d. and mutton 3½d. per pound. In 1811, according to Mr Wakefield's information, the wages of common labour were L.12 for the half-year; and, in hay and corn harvest, 1s. 8d. per day; the price of potatoes 3d. per stone; beef and mutton, 7d. per pound; oatmeal, 12s. 6d. per cwt.; milk, 2d. and butter-milk, 1d. per quart. The English language, according to Dr Macparlan, is general, though, in the mountain barony of Erris, many are entirely ignorant of it; but Mr Wakefield found the Irish universally spoken.

Fisheries.

Killala, in some seasons, employs fifty boats in the herring-fishery. At Killery Bay, on the south-west, and Ballina, on the north-east, there are considerable salmon-fisheries, and smaller ones at Newport, and other places.

Manufacture

The linen manufacture is the only one that affords a surplus beyond the wants of the population;

but, though it is general throughout the county, it is not conducted on a great scale by individuals. At Castlebar there is a linen-hall. The other articles are coarse woollens for home consumption. At Newport a number of girls are employed in making straw bonnets.

The county of Mayo sends two members to Parliament; the Marquis of Sligo and Lord Viscount Dillon have the greatest influence. On the estate of the latter alone there are 2100 registered freeholders. The number of inhabitants, in 1790, is stated by Dr Beaufort at 140,000. The great majority are Catholics; throughout some districts, of fifty miles in extent, there is not one Protestant church.

See Dr Macparlan's *Statistical Survey of Mayo*, and the works quoted under the former Irish counties. (A.)

MEATH, a county in Ireland, in the province of Leinster. Its boundaries are Louth, with a small portion of Monaghan and Cavan on the north; the Irish Sea and the county of Dublin on the east, Kildare on the south; and West Meath and Longford on the west. From east to west it extends about 44 English miles, from north to south 37, and contains 965 English square miles, or 617,600 English acres, of which only about a twelfth part consists of bogs and wastes. This county, which gives the name to its diocese, is situated in the ecclesiastical province of Armagh; its divisions being twelve baronies, and 147 parishes. The river Boyne, which intersects it in a north-eastern direction, forms a line of separation between its northern and southern parts, the former being called the Kells, and the latter Dunshauglin. Having but a few miles of sea coast to the south of the Boyne, and no other rivers of any size, it has no harbours of its own, but easy access to Drogheda, the greatest corn-market in Ireland, situated on the Boyne, in the contiguous county of Louth.

Meath is, in general, a low, flat, rich tract of country, with a soil of clay or strong loam, incumbent upon limestone or gravel, not remarkable for natural scenery, and having little wood, but containing a few splendid mansions, extensive plantations, and the remains of many religious and military buildings. In its climate it differs little from that of the adjacent counties of Dublin and Louth already described. The principal river is the Boyne, which enters this county from Kildare on the south-west, and passing by the town of Trim, northward to Navan, meets there the Blackwater from the county of Cavan, and from thence flowing westward by Slane and Drogheda, falls into the sea a little below the latter town. It is navigable for small craft to Navan, and for vessels of considerable size to Drogheda. The other streams are inconsiderable, such as the Athboy and Marnoch, which fall into the Boyne, and the Nanny water, which discharges itself directly into the sea.

Meath does not, as far as known, abound in minerals. Copper is wrought at Walterstown, south-west of the Boyne. A coarse pottery has been carried on near Knock, in the barony of Morgallion; and in the barony of Navan, on the lands of Ardraccan, is what is called the "White-quarry," which furnishes a limestone of a beautiful whitish colour, but which

Meath. becomes almost black by exposure to the atmosphere ; it is supposed to have been worked for several centuries.

Estate. The landed property of Meath is divided into large estates, a great many of which yield an income of upwards of £2000 a-year. These are for the most part let out on leases of 21 years and a life ; but on some of them there are leases in perpetuity, which have now become more valuable than the freehold property. In 1818, the rent was from £2 to £3 the Irish acre.

Grazing is or was, till very lately, a more important object in this county than tillage. Many persons fattened from 300 to 500 cows in a season, besides bullocks and sheep. These they purchase at the beginning of the grass season, and dispose of during the summer and autumn as they are ready, instead of keeping a regular stock all the year. The pastures are considered too valuable to be applied to the rearing of stock. Dairying is not carried to any extent, and the butter made here is said to be held in little estimation. In some instances, where farms are let out for the dairy, the landlord supplies a succession of cows in milk, horses, and land, and the tenant furnishes labour, utensils, &c. paying at the rate of from £6 to £7, 10s. *per annum* for each cow. The English long-horned cattle were introduced many years ago into this district, which now contains some of the best specimens of the breed. The sheep are brought from other counties, and, like the cattle, the same stock is kept only for a season.

Farm. Tillage farms are larger here than in most parts of Ireland ; but, according to Mr Curwen, who visited Meath in 1818, the system of management is little better than on the small farms of other districts. The houses and fences are for the most part of the worst description, especially the cabins of the farm labourers, which are miserable mud-walled hovels, sunk below the level of the ground adjoining, and occupied by cows and pigs, in common with the family. The principal food of this class is potatoes with churn-milk, and occasionally oat-meal, butcher-meat being rarely used even among the farmers ; and, to add to their privations, fuel is very scarce in different parts of the county. An uninterrupted succession of oats and other corn crops for several years is common ; in a few instances even for twenty years. " The common rotation," says Mr Curwen, " is wheat, oats, fallow, potatoes, clover, all without the application of manure." It is customary to work horses intermixed with oxen, of which six are generally yoked together, three pair deep, to a very ill-constructed plough ; yet, notwithstanding this management, the wheat crops are in some parts excellent.

Manufactures. Manufactures do not afford employment to any considerable part of the population, though here, as in most parts of Ireland, that of linen is carried on to some extent ; and also the weaving of cotton. On the Blackwater and the Boyne there are several extensive flour mills, at which much of the wheat grown in the county is made into flour before being sent out of it. The towns and villages are Trim, where the county assizes are held, Kells, Duleek, Ratoath, Athboy, Slane, Navan, which has a communication

by water with Drogheda, Newcastle, Dunshaughlin, Moynally, and Clonard : none of these return members to the Parliament of the United Kingdom. Of the two members for the county, the Catholic interest, according to Mr Wakefield, is powerful enough to return one. The same author estimates that the Catholics are to the Protestants as 40 to 1, which, from other parts of his work, seems to be much too large a proportion for the former. The leasehold, and much of the personal property, belongs to Catholics. According to Dr Beaufort, the population, about 1790, was 112,400, and it is known to have increased considerably since.

See the *Works* of Beaufort, Newenham, and Wakefield, as quoted under the former Irish counties ; Thomson's *Survey of Meath* ; *The Parochial Survey of Ireland* ; Curwen's *Observations on the State of Ireland*, 1818 ; and, for antiquities, the article MEATH in the *Encyclopædia*. (A.)

MECHAIN (PETER FRANCIS ANDREW), a well known practical astronomer and geographer, was born at Laon, 16th April 1744.

His father was an architect, and educated him, with the intention of making him his successor in his business. He was afterwards obliged to take charge of two young men at Sens, as their private tutor ; and he accidentally became acquainted with Lalande on occasion of the sale of a fine instrument which he had procured, and of which Lalande became the purchaser ; and it was under Lalande's patronage that he was brought forward as an observer, surveyor, and computer. He made two voyages with Mr de la Bretonniere, and assisted him in surveying some parts of the coast of France. He was afterwards employed in various computations by the Marquis de Chabert and the Duc d'Ayen.

Having obtained a prize from the Academy of Sciences in 1782, for a *Memoir on comets*, he became a member of the Academy the same year. Having proved that the hopes entertained by some astronomers of recovering an old comet were unfounded, he made up in some measure for the disappointment, by finding them eleven new ones in the course of eighteen years : and he computed the orbits not only of all these, but of thirteen others, which had been discovered by other observers : emulating in this department the labours of both his predecessors, Messier and Pingré.

About 1785, he undertook the publication of the *Connaissance des Temps*, and continued it till he was employed in geodetical operations at a distance from Paris. He was appointed, together with Cassini, de Thury, and Legendre, to make a committee to meet the English astronomers for the determination of the relative situation of the observatories, which had been proposed by Cassini. It was in these operations that he first brought Borda's circle into general use. He was soon after, in 1789, made a Foreign Member of the Royal Society of London.

In 1791, he was appointed, in conjunction with Delambre, to execute the intentions of the Constituent Assembly, with regard to the determination of a basis of linear measures. A variety of delays and difficulties occurred in these operations ; in Spain he was wounded in the head and in the side, by an ac-

Meath
||
Mechain.

Méchain.

accident which occurred while he was inspecting a water-wheel; and the political circumstances of the times produced many embarrassments, which caused him to linger in Italy perhaps a little longer than was actually necessary; but the establishment of the *Bureau des Longitudes*, and his nomination as a member of it, determined his immediate return to Paris. He was now director of the Observatory, and he entered with great zeal on a series of observations, which were to rival those of Flamsteed, of Bradley, or of Maskelyne; but he seems to have been a little tired of the confinement, and he readily accepted, or rather solicited, the appointment to take a part in the measurements required for the still further extension of the arc of the meridian to the south of Barcelona. But the secret motive for his seeking this humbler employment appears to have been a desire to remove some doubts which he entertained respecting the latitude of Barcelona, as it appeared after his death from his papers, that there had been a discordance of 3" in some observations which he had not made public. In this unfortunate undertaking, he paid a heavy penalty for any want of candour which may have been attributed to the concealment; shipwreck and disease awaited him; and he died at last, at his post, the 20th September 1805, of a fever, which fatigue and a bad climate had brought on. The severe stage of his illness was so short, that his son, who accompanied and assisted him in the survey, had not time to join him.

From the time of his accident in Spain he had become habitually melancholy and timid, though regardless of personal danger in the pursuit of his professional objects. His whole time was occupied in observing and calculating; he published little; and never hazarded to advance any reflections on the subjects which employed him, being probably more in the habit of acting than of speculating. He married, in 1777, Miss Thérèse Marjon, with whom he had become acquainted at Versailles. This connexion was in every respect happy; he was indebted to it for a competent fortune, and he left a daughter and two sons.

1. Of his publications we find the most important in the *Mémoires des Savans étrangers*; that is, besides some *Observations of eclipses and occultations*, a *Memoir on the comets of 1532 and 1661*; showing that they are not the same; and their non-appearance seven or eight years afterwards fully justified his conclusions, and the adjudication of the prize.

2. In the *Memoirs of the Academy*, from 1782 to 1784, there are several of his *Observations of transits, eclipses, occultations, and comets*.

3. There are also some letters of Méchain in Zach's *Geographical ephemerides* about 1800, on the instruments of the *Parisian Observatory*, and on other subjects.

4. He edited the *Connaissance des tems*, from 1786 to 1794. See LALANDE.

5. *Base du système métrique, décimal*. 3 v. 4. Paris, 1806, 1807, 1810. The joint work of Méchain and his respectable and indefatigable friend and colleague Delambre.

[Delambre, *Mém. Instit. Sc.* VI. 1806, p. i.; and Merionethshire. in *Biographie Universelle*, XXVIII. 8. Paris, 1821.]

(M. E.)

MERIONETHSHIRE, a maritime county of North Wales. It is bounded on the north by Carnarvonshire and Denbighshire, on the east by the latter county and Montgomeryshire, on the south by Cardiganshire, and on the west by the Irish Channel. It is of a triangular shape, contracting towards the south. Its length from north to south is 36, and its greatest breadth 34 miles. Its area is estimated at 691 miles.

There are few parts of the British Islands on which the scenery is more varied, the surface more irregular, or the prospects more romantic. Many of the peaks of the lofty mountains are near to each other, with deep valleys, or rather chasms between, and in other parts, the variety of objects forming striking contrasts with the vicinity of the sea, give a most picturesque collection of pleasing, though sometimes terrific views. The principal mountains, and their heights above the level of the sea, are Cader Idris, 2914 feet, Arran Fowdy, 2955 feet, Arrenig, 2809 feet, Cader Ferwyn, 2563 feet, and Pengarn, 1510 feet. These mountains consist principally of granite, porphyry, and other unstratified rocks, while the secondary hills are composed of different kinds of schistus.

The principal rivers are the Dee, which runs through this county, and after passing the beautiful town of Corwin, enters Denbighshire; the Maw or Mawddach, which rises in the middle of the county, and empties itself into the Irish Channel; the Dovey, which rises near a pass in the mountains leading to Montgomeryshire, and forming at last a large estuary, enters the sea at Aberdovey; and the Gleslyn and Dwyrid, whose streams unite before entering the ocean. These rivers receive the waters of numerous brooks and rivulets which trickle from the mountains, and in their course fertilise the valleys through which they run. There are several lakes, of which, the most considerable for extent, as well as for beauty, is Llyn Tegid, near Bala, sometimes called Pimblemere. It is about four miles in length, and three quarters of a mile in breadth. Its banks are most beautifully adorned with slopes, partly covered with woods, and partly exhibiting verdant pastures. Llyn Talyllyn, at the foot of Cader Idris, is less extensive, but scarcely less beautiful. Some fine cataracts add their beauty to the other romantic scenery of this county; of these Rhaidr Ddu and the fall of the Glyn near Port Llyn Dyffws are the most remarkable; but several smaller ones will well reward the labour of the traveller who delights in the picturesque.

The agriculture of the county is in a very imperfect state, though the spirited exertions of some large proprietors have recently exhibited specimens of great improvement. Nearly three-fourths of the county is uncultivated, and much of that part is unproductive waste. Large portions of the marsh lands on the coast have, by inclosing, embanking, and draining, been converted into rich pasture, and much more requires only the application of capital to

Merionethshire—bring it into the same state. Very little of the land is adapted to the plough, and the principal pursuit of the farmers is breeding and rearing cattle. The heifers from this county are sent in droves to the fairs in the south of England, and when improved by good pasture, are found very valuable beasts. The sheep are of small size, the flesh of which is highly prized, and their wool forms the material for the domestic manufactures.

Trade and Manufactures—

There are scarcely any manufactories that can be noticed, except a few coarse woollens; the females of all the families, however, employ themselves in knitting hosiery goods from the native wool. These furnish considerable quantities of the caps called Welsh wigs; and gloves, and stockings, the only goods that are sent out of the county, and the annual value of which is estimated at £25,000. The only trade is from the harbour of Barmouth, situated on a small arm of the sea, into which several rivulets empty themselves. The port is difficult of entrance, and but little frequented. It is chiefly devoted to coasting trade; exporting oats, barley, butter, cheese, oak-bark, and timber, and importing coals, culm, and groceries. On account of the excellence of the beach, and the romantic beauties of the surrounding country, it has been much frequented of late years for sea-bathing.

Population—By the census of 1811, the population amounted to 30,924 persons, of whom 14,308 were males, and 16,616 females. It has increased less between the enumeration of 1801 and that of 1811 than any other county of England or Wales. The only town is Dolgellen, where the assizes are held, which contained 3064 inhabitants.

The most remarkable seats are those of Sir Robert Williams Vaughan, at Naunau; of Mr Oakley, at Tany Bwlch Hall; Sir Thomas Mostyns, at Cors y Gedel, and Mr Corbet, at Ynysynaengwyn. It returns to Parliament one member for the county.

See Evans' *North Wales*; Davies' *Agriculture of North Wales*; and Aiken's *Tour in Wales*. (w. w.)

MESSIER (CHARLES), a celebrated astronomer, born at Badonviller, in Lorraine, 26th June 1730.

He was the tenth of twelve children, and lost his father when he was 11 years old. He came to Paris at 20, and had then to seek his fortune, having only learned to write a good hand, and to draw. Delisle employed him as a copyist in the observatory. Li-hour, his secretary, taught him to make use of the common instruments of astronomy, to observe eclipses, and to look out for comets; and this was the principal business of his subsequent life; for he was never much of a theoretical or philosophical astronomer. Delisle obtained for him an appointment as clerk in the Hydrographical Department of the Navy, and gave him his board and lodging in his own house: and he claimed in return the singular gratification of keeping all Messier's observations of comets secret for his own private amusement, until their novelty was completely lost.

Messier had already discovered 12 comets when he lost his wife; his attendance on her sick-bed prevented his discovering a 13th: and it is said that the circumstance added not a little to his grief for

her loss. He afterwards became Astronomer to the Navy, instead of being only a clerk in the department. He obtained a seat in the Academy with some difficulty, and not till 1770; being considered as too mechanical an observer to have a very strong claim to that distinction. He was fond of drawing charts of the paths of comets, and of other astronomical phenomena; one of these procured him the honour of being made an Academician of Berlin, and another, with Laharpe's interest, obtained him the same distinction from Petersburg. He was also made a Fellow of the Royal Society of London, in 1764. The highest compliment that he ever received was paid him, perhaps without sufficient reason, by Lalande, who inserted, in his celestial globe of 1775, a constellation with the name of Messier, or *Messium custos*, The Harvest Man; in the neighbourhood of Cepheus. When Herschel had discovered the Georgian planet, he was very diligently engaged in observing its motions; but, in the mean time, his studies were interrupted by an unfortunate accident: he fell into an ice-house, in a garden, which he mistook for a part of a grotto, and fractured an arm and a thigh. He was long in recovering, and he obtained a small pension on the occasion, from the royal bounty, by the solicitations of Mr Sage and some others of his friends, who had interest. He was, however, soon deprived of it by the Revolution; but he continued his pursuits as a private individual, and he amused the last days of the President de Saron by communicating to him his observations, which Saron continued to compute during the imprisonment that was terminated by his barbarous execution. Messier was in some measure compensated for his pecuniary losses by being made a Member of the Institute, of the Bureau des Longitudes, and of the Legion of Honour. He lived, without disease or material infirmity, to the age of 82, when his sight began to fail him, and he required a deep glass, which he found it fatiguing to use. He had afterwards a paralytic attack; but he lived to be near 87, and died of a dropsy, or probably rather of old age, the 11th of April 1817.

1. A variety of his observations, especially of Comets, are published in the *Mémoires des Savans étrangers*, V. VI.

2. After his admission into the Academy, he was a constant contributor to its *Memoirs* from 1771 to 1790. His papers consist almost entirely of *Observations of comets and eclipses*, with some *Accounts of Aurorae Boreales*. There is also a *Catalogue of Nebulae* in 1771; *An Account of points of light seen on Saturn's ring* in 1774; and of *An apparent fall of globules over the sun's disc*, 1777.

3. In the *Connaissance des tems*, there is a collection of his *Observations of the eclipses of Jupiter's satellites*. He had an excellent sight, and excellent telescopes; and he made the duration of the eclipses almost always shorter than other astronomers.

4. He contributed some articles to the *Astronomical Ephemerides* of Professor Hell, published at Vienna.

5. The *Voyage de Courtanvaux sur la frégate l'Aurore*, 4. Paris, 1768, was written by Pingré;

Messier.

Messier
||
Meteor-
ology.

the observations are Messier's: the purpose of the voyage was to make trial of several astronomical instruments.

6. His only separate publication was entitled *Grande comète qui a paru à la naissance de Napoleon le Grand*, 4. Paris, 1808. It was probably not calculated for immortality, even if it was a genuine work of Messier.

7. Delambre is in possession of a number of his unpublished observations of the solar spots; but he found their results, when computed, somewhat unsatisfactory.

[Delambre in *Biographie Universelle*, XXVIII. 8. Paris, 1821. See also *Eloge de Delisle*, by Lalande, in *Necrologe des hommes célèbres de France*. 12. Paris, 1770.] (X. A.)

Meteor-
ology.

METEOROLOGY,

FROM *meteoros, sublimis*, is that science which describes and explains the various phenomena which occur in the region of our atmosphere. It has deeply engaged the attention of men in every state of society, from the roving savage to the refined votary of wealth and pleasure. The moment we cross our doors, we commit ourselves to the influence of the weather. But the hardier classes of the community, the shepherd, the ploughman, and the mariner, whose labour creates or procures the staple articles of life, are always exposed, by their occupation, to the mercy of the elements. They were hence led, by the strongest motives, to examine closely the varying appearance of the sky, and to distinguish certain minute alterations which commonly precede the more important changes. No doubt they would often mistake the indications of those aspects, and would infer conclusions from mere casual circumstances. Those tokens which portend the more violent convulsions of the atmosphere—the pelting storm, or the careering tempest—are generally of a decided character; but the symptoms which go before the ordinary fluctuations of the weather can only be dimly conjectured by long experience and sagacious observation. This shadowy knowledge, this dubious and very limited anticipation of the changes which arrive in the medium we breathe, is merely the fruit of personal assiduity and application. Like the conclusions which men of discernment form to themselves on the subject of physiognomy, it is scarcely communicable; it receives, therefore, no accessions in the progress of ages, but perishes with the individual.

Origin of
the Science.

The vague rules which experience had formed on the subject of atmospheric changes were adopted by the philosophers of antiquity, and incorporated into their cosmological systems. But in attempting to explain the phenomena, they sought merely to satisfy the imagination; and the supposition of certain elements, each endued with peculiar properties, appeared, on a superficial view, to connect harmoniously the general facts.

In the infancy of science, however, it was very difficult to distinguish between such appearances as are only incidental, and those constant presages which invariably anticipate their effects. The different fluctuations that happen in the lower atmosphere seemed dependant on the influence of the heavenly bodies, which are continually altering their places. Not only the sun and moon appeared to rule the seasons, but the planets, and even the fixed stars, were conceived

to retard or accelerate, by their feebler action, the revolution of the grand cycle of changes. The application of the term *aspect* to the positions of those remote bodies implied a principle of intelligence, and the *stellar influence* shed by them might, therefore, be deemed capable of producing all the variety of effects. Hence the origin of *Physical Astrology*, which has, during so many ages, maintained ascendancy in the world, and still colours the verses of our poets, and pervades the creed of the vulgar.

The heat evolved by the luminous particles transmitted from the sun, as they lose themselves among the lower strata of our atmosphere, or under the surface of the land and the sea, varying in its intensity, according to the obliquity of their incidence, and the extent of medium which they traverse, produces the most important effects in the great economy of the globe. But the correct knowledge we have at length acquired concerning the mutual action of bodies, contracts the limits of the supposed celestial influence almost to a point. The light of the moon does not amount to the 100,000th part of that of the sun, and the heat which this very feeble illumination excites or communicates, has never been detected by the most delicate instruments, or the best devised experiments. But all the rays shot from the planets, and from the whole constellations of fixed stars, are quite lost in the contrast with those lunar beams. Their combined impressions, during the lapse of countless ages on the atmospheric temperature, would hence elude the utmost powers of calculation.

It is only by their attractive force that the heavenly bodies, except the warming energy of the sun, can ever affect the constitution of this globe. As by their action unequally exerted over its surface, they raise tides in the ocean, so they must likewise agitate the atmosphere with a corresponding reciprocation. This effect, however, depends much more on the proximity of the disturbing body, than on its magnitude or density. Thus the sun, with twenty-three million times the mass of the moon, yet being about four hundred times more distant, has only about the third part of her influence in causing the tides. But, according to the computations of Laplace, the joint action of the sun and moon is only capable of producing a tropical wind, flowing westward at the rate of about four miles a-day; a quantity too small evidently to be ever subjected to observation, and certainly insufficient to occasion any immediate and practical results.

It may be calculated, that Jupiter and Venus, in

Tides of the
Atmosphere

Meteor-
ology.

those parts of their orbits which approach the nearest to the earth, affect the aerial tides by a force of 76,000 and 82,000 times less than the sun. Those planets could, therefore, excite a most minute shifting in the atmosphere, limited to a foot in the space of 14 or 15 days or about a single mile in 20 years. As the mass of Mars is unknown, its disturbing force cannot be estimated, though it is less than that of Jupiter. But the combined influence of all the rest of the solar system is, from their great distance, incomparably smaller.

Efficacy of
the Stellar
Influence.

Nothing can be so utterly groundless, therefore, as the disposition to refer the ordinary changes of the weather to the influence of the moon. But, compared with this, the fancied efficacy of the stellar aspects, which was for ages firmly believed by the learned world, vanishes into the shadow of a vision. Nor has the most elaborate examination of numerous registers of the weather disclosed any precise and constant connection between the phases of the moon or the positions of the stars, and the succession of atmospherical phenomena. The inferences which seem to indicate a different conclusion, may be fairly disregarded, as drawn only from a loose and imperfect inspection of facts.

Cycles of the
Weather.

It cannot be disputed, however, that all the changes which happen in the mass of our atmosphere,—involved, capricious, and irregular as they may appear,—are yet the necessary results of principles as fixed, and perhaps as simple, as those which direct the revolutions of the solar system. Could we unravel the intricate maze, we might trace the action of each distinct cause, and hence deduce the ultimate effects arising from their combined operation. With the possession of such data, we might safely predict the state of the weather at any future period, as we now calculate an eclipse of the sun or moon, or foretell a conjunction of the planets. Although the protracted chain of combinations has been completed, the same series of events must again be repeated through the boundless lapse of ages. As all the anomalies of the planets are periodical, so likewise the successive varieties follow some cycle of vast extent. In the remotest annals of atmospherical phenomena, we might descry a gleam of futurity, and read the changes which still lie hid in the womb of time.

But, besides this great cycle, there probably are much shorter interior and subordinate periods, in which the weather nearly, though not absolutely, returns after the same order. Whatever principles concur to modify its succession, the revolutions of the sun and moon are certainly the primary and predominant causes. The character of the weather is accordingly strongly marked by the vicissitudes of day and night, and by the annual repetition of summer and winter. The menstrual action of the moon escapes correct observation; but, accumulated during a sufficient time, it may possibly produce a decided influence. Every 19 years the motions of the moon come to coincide with those of the sun, and her nodes perform their revolutions in nearly the same time, or about 18 years. This period, or the half of it, has therefore not improbably some slight connexion with the usual series of the changes of the weather.

VOL. V. PART II.

Meteor-
ology.

"If the sages of antiquity be justly blamed for adopting implicitly the notions and prejudices of the vulgar, those of modern times may be charged with too eager a disposition to reject whatever savours of popular opinion. A collection of the numerous rules and remarks formed in the course of ages among different orders of men, deeply interested by their occupations in watching the changes of the sky, would undoubtedly contain some important truths, which the diligence and sagacity of the philosopher might discriminate, and employ for the basis of beneficial speculations. The most sanguine can hardly uphold the prospect that mankind will ever arrive at such a pitch of knowledge, as to be capable of prognosticating the future modifications of the atmosphere, with the same precision with which they can foretell the successive revolutions of the heavenly bodies; yet the motions, however irregular in appearance, which prevail in the element that we breathe, are, equally with those performed in the regions of space, the result of certain fixed laws. The variable aspect of the sky proceeds partly from the direct action of the sun-beams, but principally from the winds which they excite and maintain. The unequal gravitation of the different portions of our atmosphere to the sun, and to the moon especially, must occasion some small effect in producing or altering the aerial currents; and even the disturbing forces of the planets have a remote share, how minute soever, in the formation of meteors. Nor can we hesitate to conclude, with the late ingenious and eloquent M. Bailly, whose fate demands the tribute of a tear, that the notions, so widely spread among men, of the aspects and influences of the celestial bodies, are only the corrupted remains of astronomical science, already advanced to high perfection in some distant age of the world. If motions were to rise and cease instantaneously with the operation of their causes, the same succession of seasons would exactly attend on each revolution of the sun; but the currents of air acquire velocity by degrees, and thenceforth continue to flow till their force is spent. The varied face of our terraqueous globe will, therefore, modify the direction, the power, and the duration of the winds, raised by the action of the solar rays. Hence an extreme complication of causes, which will produce an immense series of fluctuating events. That profound geometer, M. de la Grange, has established by demonstration that all the changes arising from the disturbing forces in the planetary system are subjected to certain vast cycles, on the return of which the same motions are perpetually renewed. Similar periods, but of an extent that affrights the imagination, probably regulate the modifications of the atmosphere; for, whenever a coincidence of circumstances prevails, the series of appearances must inevitably recur. The aggregate labours, indeed, of men continually transform the face of our globe, and consequently alter the operations of natural causes:—but, if the agency of animals be stimulated and determined solely by the influence of external objects, it follows that the re-actions of living beings are comprehended in the same necessary system, and that all the events within the immeasurable circuit of the universe are the successive evolution of an ex-

T 1

Meteor-
ology.

tended series, which, at the returns of some vast period, repeats its eternal round during the endless flux of time. Besides the grand cycle, there must evidently be many intermediate smaller periods, at the lapse of which our atmosphere will present nearly, though not exactly, the same fleeting aspects. Whether these bear any decided relation to the lunar revolutions, cannot with certainty be affirmed. A copious collection of registers formed in the course of ages will probably, at some future time, lead to the discovery of certain remarkable periods, which will enable men to conjecture, with tolerable precision, the succeeding changes of the weather. It would be most advisable, perhaps, to begin the inquiry with the tropical countries, in which the seasons are more uniform, and to advance by degrees into the temperate climates. In the mean time, our prognostications may be greatly assisted by observing and studying the concatenation of *phenomena*. Certain coincidences of aspects mark the near recurrence of some small portions of the general series, and afford scope for the doctrine of chances." (*Monthly Review for September 1795*, Art. I. p. 14.)

Necessity of
recurring to
Correct Ob-
servations.

Such views of the cyclical returns of the varied seasons may expand the imagination, but will be considered rather as curious speculations, than as definite conclusions which can ever be reduced to real and actual application. To improve meteorology we must submit to tread a humbler path; we must study closely, and by the aid of delicate instruments, the constitution and modifications of the atmosphere, and pursue, under various circumstances, and in different parts of the globe, a lengthened train of careful and precise observations. The ordinary registers of the weather are of a very modern date, and besides being for the most part unskillfully kept, they seldom record more than the state of the barometer and thermometer, which afford not any complete indication of the disposition of the atmosphere. No wonder that meteorology, though cultivated from the earliest times, has advanced the most slowly to the perfection of science.

To prepare the way for establishing meteorology on a solid basis, we shall *first* inquire into the extent and constitution of the medium which we breathe; and shall *next* review the different philosophical instruments which assist external observation, and indicate at all times the exact condition and qualities of that mutable fluid.

Height of
the Atmos-
phere &c.

The ancients imagined that our atmosphere, the seat of care, mortality, and corruption, reached as far as the moon, beyond which was a boundless expanse of resplendent æther, the abode of celestial beings, exempt by their nature from all anxiety, and absorbed in the enjoyment of eternal bliss. But the discovery of the weight and pressure of the air destroyed at once this magnificent vision. Comparing the length of the mercurial column with the density of the actual medium, it followed, that if the atmosphere had been an uniform fluid it could not exceed the elevation of five miles. But the air being very dilatable, the higher portions of the mass which covers our globe, sustaining a diminished pressure, must swell upwards, and occupy a proportionally wider space. This property hence removes the boundary of the atmosphere to a much greater elevation.

By means of an excellent pneumatic machine, air can be rarified about a thousand times; but this degree of rarefaction would not occur below the height of forty-two miles in the atmosphere. Such is nearly the limit deduced from another consideration, first proposed by the famous Kepler. This most original and inventive philosopher conceived, that the depression of the sun below the horizon, when twilight closes around us, might furnish the data for discovering the altitude of the portion of sky which reflects his latest parting rays. Let C (see fig. 2, Plate XCVII.) be the position of a spectator on the surface of the earth, and A represent the point where the sun sets, the tangent AB will mark the track of his lowest ray, which illuminates the upper part of the atmosphere at B, whence the emission of a secondary ray BC will barely reach the ground at A. But assuming the mean estimate of astronomers, that twilight expires when the solar depression or the arc CA amounts to eighteen degrees. In the right-angled triangle COB, the base OC, or the radius of the globe being 3956, and the acute angle COB nine degrees, or the half of AOC the hypotenuse OB is easily found, and hence about 49 miles is the excess BD of CB above CD, or the elevation of the boundary of the atmosphere, illumined by the latest beams of the sun. A correction might be required for the deviation of the rays from their rectilinear path, in consequence of the unequal refraction of the different strata of the atmosphere; but in a question of this kind, resting on rather loose or doubtful observations, it seems superfluous to affect any delicacy of calculation.

Meteor-
ology.

The inference drawn from the limits of twilight is not so conclusive as might at first appear. The feeble slanting rays, shed from the higher regions of the atmosphere, may not have been received directly from the sun, but derived, after repeated reflexions, from the more distant parts of the sky. The very ingenious Lambert attempted to distinguish, besides the primary twilight, a secondary, and even a ternary *crepusculum*. It is easy to see, that the solar ray SA (Fig. 3, Plate XCVII.), after grazing along the surface, will illuminate the upper atmosphere at B, from which some light will be darted in the direction of the tangent BCD, to tinge another elevated portion of the sky at D, which may cast a few expiring rays to the spectator at E, or shoot onwards to the opposite sky at F, and thence reach in a state of almost extinction the ground at G. While the first *crepusculum*, therefore, sets in the west, the second will travel like a bow over the heavens, followed at a regular distance by the dusky veil of the third, or the vanishing train of the fourth. But it may be computed, from the vast length of the tracks which the light would have to traverse, that those shades would in succession be ten thousand times darker. The clearest sky, however, on the close of evening, never appears marked by such contrasted boundaries. The vault of heaven seems to darken by insensible transitions, from the western to the eastern horizon. It is most probable, therefore, that the diminution of light, after the close of evening, is owing to the prodigious rarefaction of much higher portions of the atmosphere, which still catch some faint rays of the sun, without being able, from excessive attenuation, to reflect them efficiently to the earth. But since, unless the sky be overcast, there is

Lambert
Investiga-
tion.

Meteorology.

total darkness in no climate, even at midnight; we may, therefore, infer that the body of air extends to such an altitude, as to receive the most dilute glimmer, after the sun has attained his utmost obliquity, and sunk ninety degrees below the horizon. It would thence follow, that the elevation of the atmosphere, must be equal at least to 1638 miles, or the excess of the hypotenuse of an isosceles right-angled triangle having 8956 miles, or the radius of the earth for its base.

Extreme Elevation of our Atmosphere.

This very great extension of a rare expansive atmosphere appears conformable to the general phenomena. But the thin investiture of our globe, at least, near the equator, may stretch out much farther; and yet its elevation can never exceed a certain absolute limit. The highest portions of the atmosphere, which is carried round in 23 hours and 56 minutes, by the rotation of the earth about its axis, would be projected into space, if their centrifugal force at that distance were not less than their gravitation towards the centre. But the centrifugal force is directly as the distance, while the power of gravity is at its square. Consequently, when the centrifugal force at the distance of 6.6 radii of the earth is augmented as many times, the corresponding gravitation is diminished by its square or 43.7 times, their relative proportion being thus changed to 289. Now, the centrifugal force being only the 289th part of gravity at the surface of the equator, it will therefore just balance this power at the distance of 6.6 radii from the centre, or at the elevation of 22,200 miles. On this hypothesis, fig. 7, Plate XCVII. will represent our globe encompassed by its atmosphere, of which the equatorial diameter extends from A and B.

Such is the extreme boundary of atmospheric expansion. Though it surpasses all our ordinary conceptions of the space occupied by that dilatable fluid, it yet scarcely exceeds the twentieth part of the distance of the moon, which was held by the ancients to communicate with our atmosphere. If it really spreads out to the limit now assigned, it must, in its remote verge, attain a degree of tenuity which would utterly baffle imagination to conceive. Perhaps the fluid itself may change in those lofty regions, and pass into a sort of æthereal essence, more analogous to diffuse light than to a mass of air.

Constitution of the Atmosphere.

The constitution of the atmosphere forms the next object of inquiry. The analysis of that rare medium is one of the finest discoveries of modern chemistry. It appears to consist of two distinct expansible fluids combined in different proportions, a single portion of oxygen gas being united to three parts by weight, or four parts by bulk of azote. There is also a very slight admixture of carbonic acid gas, amounting to perhaps the thousandth part of the whole. It may be doubted, however, whether this analysis be complete. The combination of those gases obtained artificially generates a fluid in which we can hardly recognize the ordinary qualities of atmospheric air. Some fugacious elements must therefore escape during the process of decomposition. Indeed, the air may be considered as an universal solvent. It is the medium of all smells, and must therefore dissolve the different odorous effluvia, and transmit them to the olfactory nerves. The presence of moisture may perhaps assist the solution, but the

mass of air is still the great receptacle of those diffusive emanations. We can readily distinguish several earths and stones by their difference of smell. Nay, the metals themselves, especially when rubbed, emit peculiar odours. What can be more variously contrasted, for instance, than the smells of iron, *vitæ*, and of copper? The air must hence actually dissolve some traces of those metals, highly attenuated indeed, and almost evanescent. If a lump of *assaætida* loses but a grain by exposure for several weeks, a bright surface of copper may, in similar circumstances, suffer the waste of only the thousandth part of a grain. The metal, if not encrusted by oxydation, would consequently experience a certain diminution, however small, in the course of ages.

The atmosphere is thus charged with emanations of all the various substances which it sweeps. To detect such dilute corpuscles wholly transcends the powers of chemical analysis. It seems probable, that the air holds some matters in more copious solution than others; and the phenomena of the aerolites lead us to suspect that it attracts iron and nickel with greater force than the rest of the metals. The quantity of those adventitious particles contained in a given mass of air may be exceedingly small, and yet the aggregate weight diffused through the whole atmosphere would form a considerable amount. It appears from numerous endiometrical observations, which agree tolerably well when performed in a similar way, that the constitution of our atmosphere is the same in all places on the surface of the earth, and at every elevation which has been yet explored. Such experiments have been made at very distant points, repeated on the summits of the loftiest mountains, and applied to portions of air brought down by balloons from the altitude of five miles. The result is what we should expect from the perpetual agitation and commixing of the lower strata of the atmosphere.

But a variety of circumstances render it extremely probable, that an expanse, far above the region of the clouds, is filled by some peculiar fluid, very different from the grosser element spread below. The shooting stars which are seen every clear night, the *bolides*, or fire balls, and the luminous arches which not unfrequently occur, and which must traverse the sky at the height of several hundred miles, all seem to indicate the existence of a very ignitable medium. Nor is it difficult to conceive how such a collection of highly inflammable fluids could be formed. Not to mention the multiplied processes of art which emit those products, the great laboratory of nature is incessantly at work in generating and pouring forth hydrogen gas, and its various compounds. The volcanic mountains cover a considerable portion of the surface of the globe, and their innumerable spiracles, with scarcely any interruption, continue to discharge immense streams of inflammable aerial fluids, a great part of which escape conflagration. But, as hydrogen gas has little attraction to common air, it rises upwards by its buoyancy, without suffering much loss in the passage through that fluid. The largeness of their volume, and the celerity of their projection, conspire to favour the ascent of those inflammable gases to the loftiest regions of the atmosphere.

A comparison of the several quantities of astrono-

Meteorology.

It is charged with various emanations.

Its higher strata inflammable.

Meteor-
ology.

mical refraction, at different altitudes, points to a similar conclusion. The refraction which the rays of light suffer in slanting across the higher regions of the air, is greater than what calculation assigns to the corresponding density of the medium. But the discrepancy would entirely disappear, if we suppose those strata to consist of hydrogen gas, which is known to possess, in a remarkable degree, the power of refracting.

It seems very probable, that the higher range of atmosphere has a sort of phosphorescent quality, or shines with a certain feeble light, for some time, after it has been heated or excited by the incident rays of the sun. Such may be the principal cause, and not any reflex illumination, of that lucid glow which, even at midnight, is diffused over the clear canopy of heaven.

Zodiacal
light.

The phenomenon of what is called the *zodiacal light*, might, perhaps, be traced to the same source. That remarkable appearance, which is more conspicuous in the finer climates, and near the vernal equinox, on the approach of evening, has often been ascribed to the extension of a supposed luminous atmosphere about the sun. But Laplace has shown, that such an atmosphere, far from stretching to our earth, would not even reach the orbit of Mercury. The zodiacal light must therefore have only a terrestrial origin. Supposing the uppermost regions of our atmosphere to consist of diffuse inflammable matter, we might infer from analogy, that like the calcined sulphate of barytes and other incinerated substances, they are endued with a phosphorescent quality, and capable of scattering a lambent gleam on being excited by the beams of the sun. But this luminary darting perpendicular rays, will evidently affect most powerfully the range of atmosphere which occurs in his diurnal track. The expansion of the gaseous investiture of our globe above the equator, will hence, from its vast elevation, be descried in places even beyond the tropics, glowing with a gentle flame. The luminous cone which converges from the sun to the distance of perhaps 30 or 40 degrees in the circle of the equator, gradually contracts and grows fainter in proportion as that body sinks further below the horizon.

It thus appears, that the opinion entertained by the ancient philosophers concerning the existence of a vast shining æthereal expanse beyond our atmosphere, is, with some modifications, consonant to the principles of sound philosophy. This is not the first occasion in which we have to admire, through the veil of poetical imagery, the sagacity and penetration of those early sages. It would be weakness to expect nice conclusions in the infancy of science; but it is arrogant presumption to regard all the efforts of unaided genius with disdain. Seldom has a discovery been made without some distant ray of anticipation.

Air may oc-
cupy the Bed
of the Ocean.

Having ventured to state that the highest region of the atmosphere is probably occupied by some very diffuse phosphorescent gas, we shall hazard a conjecture which will appear bolder, and even paradoxical, —that perhaps air, in its most concentrated state, occupies the bottom of the ocean, and forms a vast bed, over which the incumbent waters roll. Air has

Meteor-
ology.

actually been condensed above a hundred times, and during this process it betrayed no deviation from the fundamental law, that its elasticity is directly proportional to its density. There seems no reason, therefore, to doubt, that if an adequate compressive force could be exerted, air might be reduced to the thousandth part of its ordinary volume. But this elastic fluid would then be denser than water, and, consequently, instead of rising, would fall through the liquid. Suppose, for instance, a bladder filled with air, and having a small bullet attached to it, were thrown into the sea; in continuing to sink, it would reach a depth where the enormous weight of the column of water would compress it to the same density with the surrounding mass; and if the bullet were now disengaged, the bladder would remain suspended in that stratum, or if carried a little lower, it would precipitate itself to the bottom.

To form some estimate of this singular event, a simple calculation will be required. Air, of the ordinary temperature, is 840 times lighter than distilled water, and is therefore 865 times lighter than sea-water, assuming the density of this to be 1.03. But the mean pressure of the atmosphere being equal to that of a column of 34 feet of distilled water, is hence equal to the weight of a column of 32½ feet of sea-water. Wherefore 32½ × 864, or 28,296 feet, is the depth of the ocean where the necessary compression would obtain. But a small correction must be applied, on account of the augmented density of the sea-water itself under the load of such a column. The logarithm of this density is found very nearly by multiplying the height of the column by six, and striking off seven decimal places; whence the *modulus* of the compression of water may be reckoned 723,824 feet. Of this large number, the former depth is about the twenty-fifth part; consequently, to procure an equilibrium between the condensed air and the corresponding stratum of sea-water, it is requisite that the air should be contracted one twenty-fifth part more, or reduced to 901 times less than its ordinary volume. But 32½ × 900 = 29,475 feet, from which deduct the fiftieth part for the mean condensation of the column, and there remains 28,885 feet, the correct depth.

This computation is to be considered as only a near approximation, yet sufficiently accurate for the object in view. Nor shall we fatigue our readers by the investigation of a strict formula, including exponentials. It is enough to mark the conclusion, that any portion of air carried five miles and a half below the surface of the sea will never ascend again. Now, this limit is only half the depth which the theory of tides assigns to the waters of the ocean. There is more difficulty in conceiving, by what process air can be conveyed to its abyss. Increase of pressure, however, enables water to hold a larger share of air; and the effect is hence the same as an augmented attraction. The minute globules of air may therefore be gradually drawn downwards from stratum to stratum, till they are at last detached from the body of water by their own superior density. The precipitation and accumulation of concentrated air under the ocean would thus be the results of some unceasing operation. Such a pro-

Meteor-
ology.

cess may perhaps constitute a part of the great economy of Nature. It seems probable, that the existence of a subaqueous bed of air is necessary to feed the numerous fires which continually rage in the bowels of the earth, and occasionally burst forth on the surface in volcanic spiracles.

Meteorolo-
gical Instru-
ments.

The variable disposition of the atmosphere is the main cause of all the meteorological phenomena. It is of importance, therefore, to examine the theory and application of the different instruments which can be employed to explore the state of that medium. Some of these have been long in common use; but others of a more delicate and refined construction are only beginning to be known, and promise, when generally adopted, to expand our views, by opening a store of new and ulterior prospects. The ordinary observations are confined to the weight and temperature of the air. There are other data still wanted, to determine at any time the actual condition of that medium. The dryness or humidity of the atmosphere, its brightness or degree of illumination, the different depth of the cerulean hue of the sky, and the variable disposition to chill the surface of the earth, by impressions of cold transmitted from the higher regions,—these objects of inquiry should be conjoined with others of a more practical tendency, depending immediately on the mutable state of the weather. Such are the attempts to measure the daily evaporation from the ground, to register the quantity of rain which falls, and to mark the direction and indicate the force or velocity of wind. A complete apparatus of meteorological instruments will, therefore, include primarily the *Barometer*, *Thermometer*, *Hygrometer*, *Photometer*, *Æthrioscope*, *Cyanometer*; and comprehend likewise the *Atmometer*, *Rain-gage*, *Drosometer*, and *Anemometer*. We shall review this series in the order of enumeration.

Importance
of the Baro-
meter.

I. *Barometer*.—The capital discovery of the weight and pressure of the atmosphere achieved by Torricelli in 1643, was the first step in the progress of meteorology to the rank of a science. Prior to that memorable period it rested on principles altogether loose and conjectural. But the construction of the barometer, as an accurate instrument of observation, soon disclosed what was passing in the more elevated and distant regions of the atmosphere. The column of mercury, it was perceived, seldom remained long stationary, but rose and fell through a sensible space, according to the different state of the heavens. In fine calm weather it generally stood high, but commonly subsided a short while before rain or wind. The barometer came, therefore, to be regarded as a *weather-glass*, announcing the proximate changes of the sky, and owed its general reception to this belief. Its indications, however, were found, by farther experience, to be liable to much uncertainty. Though the extreme depression of the mercurial column appears invariably to foretell the ravage of a hurricane, yet its partial variations often pass away without being followed either by rain or wind. The barometer, evidently can mark only the pressure of the atmosphere, and intimate, by consequence, the state of the weather, in as far as it depends on that cause.

Attempts to
explain its
Variations.

Philosophers have eagerly sought to explain the

fluctuations of the mercurial column. They have tried every principle that might appear to exert any influence in modifying the local weight of the atmosphere; but their very numerous attempts, it must be confessed, have hitherto proved singularly unsuccessful. It was requisite to show that such causes would not only give results of the kind expected, but were besides fully adequate to the production of the phenomena. In most instances, however, either none of those effects could have followed, or they would occur in a very inferior degree and disproportionate extent.

Meteor-
ology.

All the proposed explications of the changes of the barometer may, perhaps, be referred to three distinct sources; 1. The action of heat on the atmosphere; 2. The influence of moisture on that fluid; and, 3. The impression made by its rapid motion in wind. Now, the heating or cooling of the air above any given place, could in no way affect its pressure. The only change occasioned would be in the density of the fluid; and by the influx of the portion below, or the efflux of a similar portion above, the pressure of the atmospheric column would soon become adjusted to an equilibrium with the surrounding mass. The diurnal variations of the barometer within the tropics, seldom exceeding the twentieth part of an inch, as they follow a different course from the progress of heat, are obviously not derived immediately from this cause. According to the accurate observations of Humboldt in South America, at all seasons the barometer falls from nine o'clock in the morning till four in the afternoon, it then rises till eleven at night, and from this time it again descends till half-past four in the morning, and next mounts till nine o'clock.

Influence of
its Heat;

The transition of the air, from a state of dryness to humidity, seemed to furnish the most plausible explication of the changes of the mercurial column. But the indication of the barometer was, in this case, distinctly at variance with the ordinary feelings of men. Those who suffer under a delicate or enfeebled constitution are accustomed in damp weather to complain of the air as heavier and less elastic. This language is, no doubt, metaphorical only, and descriptive of the disordered state of the nervous system; but it shows the utter fallacy of trusting in philosophical matters, to the loose results of vulgar observation and experience. Moisture, so far from loading the air by its weight, communicates, like heat, increased expansion, and elasticity. But, even supposing a column of air to become suddenly charged with humidity, before its subsequent dilatation had, by diffusing it, produced an equilibrium, still the additional pressure would have been extremely small, not exceeding, at a moderate computation, the fifteenth part of a mercurial inch. Any transition of that medium, from dryness to humidity, would be quite inadequate, therefore, to the production of the effects actually observed.

and of its
Dryness
and Mois-
ture.

Some philosophers imagine that moisture, in separating from the air, ceases to press that fluid by its gravitation, and would hence explain the fall of the barometer on the formation of clouds and the precipitation of rain. But when the aqueous particles are disunited in their solvent, whether dispersed in

Meteor-
ology.

minute globules, or collected in large drops, they must evidently descend till they acquire the celerity sufficient to maintain a resistance in the medium equal to their weight. The pressure of the whole atmospheric mass upon the surface of the earth must therefore continue exactly the same under all the changes of the constitution of the medium.

Action of
Winds.

The combined action of winds seem at first to promise the most satisfactory explication of the variations of the barometer. It is evident, that opposite currents rushing to the same quarter, will occasion an accumulation of the air; and on the other hand, different streams flowing from any point must reduce the vertical column. But such conclusions are quite vague, without being subjected to the ordeal of calculation. Now it is easy to compute that a course of winds blowing at the rate of 50 miles an hour, and hence approaching to the violence of a hurricane, would be required to raise the barometer only the tenth part of an inch. The utmost power of a tempest could not, therefore, affect the mercurial column the twentieth-part of what is frequently remarked in such circumstances. But trifling as this influence appears, it would be still at variance with actual observation. So far from rising in strong winds, the barometer almost invariably sinks; and instead of continuing depressed in the place where those currents originate, and where a calm must prevail, it generally stands high.

Hauksbee's
Experiment.

To explain the descent of the barometer during wind, a very ingenious idea has been proposed, which, being apparently confirmed by experiment, has obtained general reception. It is conceived, that a current of air, in sweeping over the surface of the earth, must cease to exert any vertical pressure. But this assumption can hardly be reconciled with any strict principle in science, for the particles of air will not for a moment cease to gravitate, nor will any horizontal motion of them produce the slightest derangement in a perpendicular direction. A remarkable experiment, however, was made by the ingenious Mr Hauksbee about the beginning of the eighteenth century, "showing, as he says, the cause of the descent of the mercury in the barometer, in a storm." Having connected the square box cisterns of two barometers by a horizontal brass pipe of three feet in length, he inserted in the side of one of the boxes another pipe opening outwards, and connected the opposite side with a pipe attached to the neck of a large globular receiver, into which three or four charges of atmosphere had been compressed. On turning the stop cock, the imprisoned air rushed with violence over the surface of the mercury in the cistern, and effected its escape, while both columns fell simultaneously about two inches, and gradually rose again as the force of the blast diminished. From this experiment Mr Hauksbee formally derives four distinct corollaries: 1. "That we have hence a clear and natural account of the descent and vibrations of the mercury in violent storms and hurricanes;" 2. "That not only the different forces, but also the different directions, of the winds, are capable of producing a difference of the subsidence of the mercury;" 3. "That strong winds may affect the animal economy, upon this very account,

of their altering the pressure of the atmosphere;" and 4. "That the weight of the atmosphere being diminished in one place, it is also as much diminished at the same time in another place, which holds a communication with the former."

Meteor-
ology.

This experiment has a specious appearance, and might seem to warrant the conclusions drawn from it. But a closer examination dispels the illusion. Since the air had been condensed four times, it must issue from the receiver with the immense velocity of 2700 feet in a second, or the double of that with which air of the ordinary density would rush into a vacuum. This is a rapidity, however, twenty times greater than the most tremendous hurricane. The very small change of the four hundredth part of an atmosphere would hence have been sufficient to produce the strongest wind ever observed, and therefore its influence in passing over the mercurial surface must have been quite insignificant.

Its Fallacy.

But the experiment itself was absolutely fallacious. The peculiar result proceeded from a mere casual circumstance, the exit pipe from the mercurial cistern being wider than the pipe which introduced the current of air. This incidental arrangement is not mentioned in the description of the apparatus, and we have, therefore, caused the original figure to be engraved on a reduced scale, not only to prove the fact which we have just stated, but also to warn experimenters of the necessity of noting scrupulously every accessory circumstance blended in their operations. (See Fig. 2, Plate XCVI.) It is easy to perceive that the tube G, which discharges the air from the box F, is much wider than the tube E, which conveyed it from the receiver A. This air, previously condensed, and still restrained in its passage through E, on entering the cavity of the box, immediately expands beyond the limit of equilibrium, and finding an easy escape through G, allows that state of dilatation over the mercury during the time of the horizontal flow. But the air contained in the other cistern K, must, from its communication by the slender pipe I, suffer a like expansion, and, consequently, the columns L and H will, in the same time, subside equally.

Such is unquestionably the true explication of this curious fact. Were any confirmation needed, it could easily be derived from a very simple experiment. Let A (Fig. 3, Plate XCVI.) be any cylinder of tin, suppose three inches long and two inches in diameter, having an open pipe inserted at B, a quarter of an inch wide, and perhaps two inches long, and another opposite pipe inserted at C, about three-eighths or half an inch wide, and one inch long; at right angles to these, a recurved glass tube or syphon, G H E, of the tenth of an inch bore, is cemented below, descending 12 inches, and rising again 6 inches to the open swell at E, which contains coloured water terminating at F. Holding the cylinder in a horizontal position, and applying the mouth at B, let a sudden blast be injected into the cavity, the water will rise instantly to G, thus showing the diminished pressure, and, consequently, the rarefaction of the air above it. But if a cap D, with a narrow projection of perhaps only the eighth part of an inch, be adapted to the exit pipe C, on repeating the exper-

Similar Ex-
periment.

Meteor-
ology.

ment, an opposite effect will take place, and the column of water, so far from mounting to G, will now sink to H. It is evidently the difficulty of the escape through D, that occasions the accumulation of the air within the cylinder, and the consequent depression of the water in the syphon. These different results are perfectly analogous to the local fall or rise of the surface of a river occasioned by the widening or contracting of its channel.

New Theory
of the Vari-
ation of the
Barometer.

After the complete failure of so many theories for explaining the variations of the barometer, which it would be tiresome to enumerate, we may be charged with presumption in attempting the solution of a problem that has racked and exhausted so much ingenuity. Yet in all these various efforts, a principle seems to have been overlooked, of extensive influence, accordant with the general phenomena, and sufficient, we think, on a close investigation, to produce the measure of effect which is required.

It is obvious, that a horizontal current of air must, from the globular form of the earth, continually deflect from its rectilinear course. But such a deflection, being precisely of the same nature as a centrifugal force, must hence diminish the weight or pressure of the fluid. The only question is to determine the amount of that disturbing influence. Though it should appear quite inconsiderable in the interval of a short space, it may yet accumulate to a very notable quantity through the wide extent over which the same wind is known to travel. Suppose a current to begin to flow from A (fig. 9, Plate XCVII.) in the direction of a tangent, it will successively bend from a rectilinear track at the points B, C, D, E, F, G, &c. on the surface of the earth. The particles of the fluid are, therefore, drawn incessantly from their course by the action of gravity. Their vertical pressure is consequently diminished, by the force spent in producing this deflection. Wherefore, during the prevalence of the wind, the atmospheric column will press with inferior weight at B than at A, at C than at B, at D than at C; thus gradually decreasing through the whole chain. Suppose the intervals AB, BC, CD, DE, &c. to be each of them a mile, and that the current reaches the points B, C, D, E, &c. in successive minutes, a celerity which frequently happens; the deflection at B, owing to the curvature of the earth, would be eight inches, or two-thirds of a foot; but the space through which a body would descend in a minute, by the action of gravity, is $60 \times 60 \times 16 = 57600$ feet, or 86400 times greater than the deviation from the tangent. Wherefore the atmospheric pressure would, on that hypothesis, be diminished by the 86400th part for each interval of a mile, from A to G. In the space of 288 miles this diminution would, consequently, be the 300th part of the incumbent weight; and over an extent of 2880 miles it would amount to the 30th part. If we assume the very probable estimate, that storms involve the whole region of the clouds, or attain an elevation of near three miles, the diminution of pressure, occasioned by a long series of deflections in the stream, would affect one-half of the atmosphere. Wherefore, a wind which has blown over a track of 2880 miles, at the rate of 60 miles an hour, might cause the mercurial column to subside half an inch. If the velocity of the wind were

doubled, which is probably the limit of the most tremendous hurricane, the fall of the barometer would be four times greater, and amount to two inches.

That the same powerful wind can sweep over an immense track of surface is well ascertained. The effects of a hurricane originating in the West Indies, at the distance of 5000 miles, have often been felt on our shores. But a wind arising at A must evidently be followed, at succeeding intervals, by a current from K, L, M, &c., the range of influence being thus extended over a larger track. During the flow of the air, the depression of the barometer at G will be maintained, or rather augmented.

These conclusions are perfectly accordant with the facts observed. It appears from comparing the most accurate registers, that the pressure of the atmosphere is subject to very nearly the same variations through a vast extent. A barometer may be considered as in unison with another placed at the distance of perhaps 200 or 300 miles, and the mercurial columns in both of them rise and fall by an almost simultaneous movement. But, in stormy weather, the separated barometers, however they may approximate in their indications, cannot absolutely correspond. The gradation of atmospheric pressure from G to F, from F to E, &c. may be very slow; and yet the minute differences may accumulate to a very sensible amount in the long range from G to A, or to M. Thus, though a barometer may stand only the twentieth part of an inch lower than another separated 200 miles, it would be half an inch below a barometer at the distance of 400 miles.

Variation of
the Barome-
ter, the
same over a
great extent.

The theory now stated seems to furnish the most satisfactory explication of a great variety of phenomena. Thus the minute diurnal alternations, to which the barometer is subject within the Tropics, are caused by the influence of the land and sea breezes. During the heat of the day, those gentle airs blow from the ocean, and, therefore, near the shore, and in the interior of the islands, the mercurial column subsides. But after the vigour of the sun's beams has declined, they flow in an opposite direction, and consequently the mercury rises again. The fluctuations are only partial, however, because such breezes hold a very short, and do not perhaps extend beyond 100 or 200 miles.

The common remark that a north-east wind, so far from depressing the mercurial column, generally causes it to rise, might appear at variance with the principles which we have advanced. But that wind which really comes from the north has probably a short course, and may be dependant on a more extensive current which maintains a flow in the higher regions towards the poles. The existence of opposite streams, though incompatible with the supposition of a wide spreading hurricane, may yet be admitted in local and partial derangements of the atmosphere.

Hitherto we have contemplated the winds, as describing only arcs of great circles about the earth; but they may be constrained to bend in smaller circles, and perhaps trace the parallels of latitude. Their flexure from a rectilinear course, being in this case augmented, they would in the same extent exert an influence proportionally greater on the barometer. Such, near the arctic regions, may

Meteor-
ology.

be the effect of a westerly wind of no very distant origin.

Explanation
of Whirl-
winds.

The same principles will explain the phenomena of eddies, whirlwinds, and tornados. Suppose (Fig. 4, Plate XCVII.) a horizontal stream of air, rushing from A to B, meets a contrary current blowing from C to D, and that some obstacle, E, occurs in their line of separation. The flow will evidently diverge on both sides of E (see Figs. 5 & 6, Plate XCVII.), till it swells by degrees into a vertiginous revolution. Such is the origin of the famous *malstroem*, or whirlpool, on the coast of Norway, occasioned by the meeting of opposite tides. The aerial vortices are evidently produced by a similar cause. If the opposite streams have equal force, the circulation will be maintained in the same spot; but if the one current flows with greater rapidity than the other, it will transport the vertiginous motion by the excess of its celerity. A motion of progression and revolution is thus upheld at the same time. Such appearances are frequently witnessed in summer, especially in the hotter climates. A whirlwind arises on a sudden, and runs over the surface of the ground, drawing into its vortex all the light substances which occur in the track. Immense havoc is often thus produced in the fields of rice and plantations of sugar-cane. It is easy to show, that if r denote in feet the radius of the extreme circle described by the whirlwind, and t the time of circumvolution in seconds, the elasticity, or pressure of the column at the verge, will suffer a diminution corresponding to the fraction

$\frac{5r}{4t^2}$. The amount of this diminution over the whole base would be reduced to three-fourths; and consequently h expressing the height of the revolving column of air, $\frac{15rh}{16t^2}$ would represent the mean effect

of centrifugal action. Suppose the whirlwind to have an elevation of 200 feet, and a radius of 50, and to circulate in three seconds, the diminished pressure would be equal to the weight of a column of $\frac{15.50.200}{16.9}$, or 1040 feet. This example, assuming a celerity of 65 miles an hour, might be reckoned an extreme case, but it would occasion the mercury to sink in the barometer more than an inch, or 1.12.

The formula for the depression of the barometer caused by a rapid whirl or tornado in the lower atmosphere, may be changed into an expression that shall embrace the velocity instead of the time of revolution. This velocity in miles each hour being denoted by v , the diminished pressure of the vertiginous column will be $\frac{3v^2h}{50r}$. It thus appears that the

effect is directly as the square of the celerity, and inversely as the radius of circumvolution. And since the rapidity of whirl can never exceed certain limits, the action of a tornado must diminish in proportion to the extent of surface which it occupies. Suppose the height of the cylinder of air to be 300 feet, the radius of the sweep 500 feet, and the celerity of its extreme circulation 80 miles an hour: Then $\frac{3.6400.300}{50.500} = 290$ feet, which cor-

responds to a descent of 1.247, or about a quarter of an inch in the mercurial column.

Meteor-
ology.

II. The THERMOMETER.—The invention of this instrument has not only dispelled the illusions which formerly prevailed on the subject of heat, but has mightily contributed to extend our acquaintance with the actual condition of the atmosphere. A lump of iron brought into the house, from its exposure during a frosty night, feels intensely cold, yet becomes gradually warmer; and if it be put into the fire, it will soon grow extremely hot, till it acquires the faculty of burning; on removing it from the fire, and laying it again out of doors, it will, through all the steps of a contrary progress, relapse imperceptibly into its former state. This obvious fact, and many others of a similar kind, might have been sufficient to show that *hot* and *cold* are nearly relative conditions which every substance is capable of assuming. The schools upheld very different notions, which, after a long series of descents, have at last found shelter among the vulgar. It was maintained that, of the four elements, air and fire are hot, and water and earth essentially cold; and that the compound bodies, from their constitution, partake of those qualities in different degrees. While the senses were the sole arbiters of heat and cold, substances became classed according to the sensations which they excited. If a body, such as lead, rapidly abstracted heat from the touch, it was reckoned cold. But the same quality was likewise bestowed on other substances of a very different kind, for instance, on vinegar and hemlock, because they affect the stomach with a sort of chilling sensation. Soft wood and feathers might be deemed warm, since they draw off heat feebly from the touch; but pepper was also ranged in the same class, because it stimulates the organs of taste. Such a confusion of ideas disfigured physical science, and perverted the practice of medicine.

The construction of the air-thermometer, by the famous Sanctorio of Padua, in 1590, was the commencement of a salutary revolution. As it was at first intended for exploring disease, it has ultimately rendered signal service to the medical practitioners. About twenty years afterwards, those instruments were manufactured by Drebbel, who carried them from Holland into England. They were very rude, however, and adapted to no constant scale, but regarded merely as *weather-glasses*. The discovery of the barometer opened new views, and showed that the former instruments marked the conjoint effects of heat and pressure. To distinguish the separate influence of heat, it became hence requisite to employ some different fluid from air. Alcohol was preferred, as being very expansible; and from the year 1655, thermometers consisting of rather wider tubes, terminating in balls or large bulbs filled with that liquid, were manufactured by Italian artists, who imitated an arbitrary standard adopted by the *Accademia del Cimento*. Such thermometers were clumsy, and susceptible of only a low range. Römer, who made the fine discovery of the progressive motion of light, proposed mercury as a fluid, sufficiently expansible, and capable of bearing an intense degree of heat. The origin of the scale was then fixed at the melting point of ice or snow, and the scale itself divided into

Invention of
the Thermo-
meter.

Meteor-
ology.

Improved
by Fahrenheit.

degrees corresponding to the ten thousandth parts of the capacity of the bulb. Yet this mode of construction seemed tedious, and liable to some inaccuracy. The capital improvement was made in 1724 by Fahrenheit, who took another standard point from the boiling of water under the mean pressure of the atmosphere. For many years that ingenious artist manufactured thermometers in Amsterdam on correct principles, very neat and small, adapted especially to medical purposes. The multitudes of young physicians who at that period studied in Holland, quickly dispersed them to every part of the globe. The observations thus obtained gave juster ideas of the comparative temperatures of different climates, and in many cases reduced the exaggerations of travellers to moderate bounds. It thence appeared that the heat of the torrid zone was not so excessive, nor the cold of the arctic regions so intense, as had been commonly represented. The tropical plants could, therefore, enjoy in our hot-houses all the warmth of their native climate. The thermometer was first applied to direct the operations of horticulture, and afterwards extended to regulate the process of brewing and other arts more immediately depending on practical chemistry.

Quicksilver was deemed preferable to alcohol in the filling of the thermometers, not only because of the wide range which it embraces, but on account of the remarkable property which it was afterwards found to possess, of expanding equally with equal accessions of heat. But it failed in the lower part of the scale. The reported sinking of the mercurial thermometer in Siberia appeared to indicate an intensity of cold beyond all conception. But the discovery made by Professor Braun, in 1759, of the actual congelation of mercury itself, reduced the extent of refrigeration to moderate limits. This fluid metal suffers a large contraction in passing into the state of solidity; and, therefore, though it freezes about 39 degrees below the zero of Fahrenheit, it yet shrinks through a space of more than a hundred degrees before it becomes fixed. As alcohol has never been congealed, though brought, in some experiments we could mention, to 150° below zero, thermometers filled with it are now employed to explore, if not to measure, intense cold.

Metallic thermometers are likewise well adapted for examining the state of the atmosphere. They are commonly constructed on the principle of the compensation balance of a chronometer, a spiral or circular spring being composed of two soldered opposite plates of distinct metals, for instance of brass and steel, or of zinc and platinum, which expand very differently under the action of heat, and therefore continually change their incurvation. Some instruments of this kind, made by Breguet at Paris, are remarkably elegant, and those more lately manufactured by that ingenious artist with a very slender form, surpass all other thermometers in the exquisite sensibility of their indications. Fig. 9, Plate XCVI. represents the first form, reduced to about the fourth part of its natural size. The main piece of mechanism is a circular spring, fixed at one end, and composed of steel and brass soldered together. The other end carries a clip, that acts on a short train of wheels, which turn an index on the dial plate, the extent of the scale, including the range of atmospheric temperature. The

dial with its index are shown by A; and B exhibits generally the interior mechanism. Fig. 4, Plate XCVI. delineates the latest improvement. To prevent the cracking, or dislocation which a large motion of the spring sometimes occasions at the junction of the two metals, a thin plate of a third metal is interposed. Three plates, consisting of platinum, gold, and silver, are united by the rolling press into a single ribband, of the thickness of only 1200th part of an inch. The instrument is formed with about twenty-seven spires or circumvolutions of this very slender spring, bearing an index which travels in its circle over 50 centesimal degrees, or 90 degrees by Fahrenheit's scale. The metallic film is, from its extreme tenuity, almost instantly penetrated by the impressions of heat or cold, and the sensibility of this thermometer accordingly surpasses all conception.

It is of much importance in keeping meteorological journals, to have thermometers that shall indicate the extreme changes which occur during the absence of the observer, such as the greatest heat of the day, and the lowest cold of the night. For this object, the metallic thermometers are easily adapted, since their index may push forward or draw back any moveable mark, and thus indicate the limits of its variation. Large mercurial thermometers also, if mounted like the wheel barometers to turn an index, will answer a similar purpose. But smaller instruments, though of a more complex construction, have been generally preferred. The *Encyclopædia* contains a sufficient account of the Self-registering Thermometer proposed by Lord Charles Cavendish in 1757, and of the more complete instrument described by Mr Six in 1782. The latter has now come into pretty general use, though we are sorry to remark, that it seems to have fallen into the hands of very inferior artists, the scale consisting merely of boxwood, rudely and inaccurately subdivided.

Both these instruments have been employed to ascertain the coldness of the ocean at great depths. It becomes requisite, however, to make some allowance for the contraction which the glass bulbs must suffer under the enormous compression of the superincumbent columns of water. This can easily be computed, from the effect of perhaps ten atmospheres in a condensing engine; and such corrections were actually applied to the observations made in Captain Phipps' voyage in 1773 towards the North Pole. It is a matter of equal surprise and regret, that all such metecies were overlooked in the late expeditions of Captain Ross and Captain Parry to the arctic regions.

The simplest, and by far the best self-registering thermometers, though barely noticed in the *Encyclopædia*, are those invented and constructed by the late Dr John Rutherford, of Middle Balilish, and first described in the *Transactions of the Royal Society of Edinburgh*, for the year 1794. The one which marks the *minimum* is filled with alcohol, and the other which indicates the *maximum* is filled with quicksilver; and they are both attached to the same frame, or, what is still better, affixed to separate frames, placed nearly horizontal, or rather elevated about five degrees, to prevent the separation of the thread of liquid. The tubes have bores from the 25th to the 15th part of an inch wide, and include a minute tapered or conical piece of ivory, or of white

ology.

or blue enamel, about half an inch long. This mark having in either thermometer its base turned towards the bulb, is drawn to the lowest point by the alcohol, which again freely passes it; but it is always pushed forward to the highest limit by the mercury, which afterwards leaves it. These marks, however, are now made cylindrical, a little thickened at the ends, and about $\frac{1}{4}$ ths of an inch in length. (See fig. 7 and 8, Plate XCVI.) Fig. 7 exhibits the alcohol or *minimum* thermometer; and fig. 8 the one which indicates the *maximum*, and is filled with quicksilver.

This instrument was first employed by Dr Rutherford in some interesting experiments, to ascertain the temperature of germination, and determine the depth to which frost penetrates into the ground in different soils and situations, at the suggestion of his neighbour, Dr Coventry, the very able and intelligent Professor of Agriculture in the University of Edinburgh, both of them proprietors in the small county of Kinross. The few instruments of this kind, for some time circulated, were made by the hands of the inventor; but artists have since learned to imitate and improve the original construction, and nothing is wanted now but to promote their diffusion. We regret that this very useful register-thermometer seems yet to be not so well known in London as it deserves.

Differential
Thermom-
eter.

The minutest changes which take place in the constitution of bodies are for the most part attended by corresponding alterations of temperature. To explore those abstruser operations of nature, which often betray the influence of more extensive principles, it was now requisite to improve the delicacy of the thermometer. To this object the writer of the present article had early turned his attention. At first he enlarged the capacity of the bulb, and thus procured degrees of such a size on the stem as to be capable of a very distinct subdivision. These instruments, however, received their impressions very slowly; and, therefore, tubes of extremely fine bores being selected, he had small bulbs blown, and filled with quicksilver, not in the ordinary way, but by the aid of a compressing force. With such exquisite thermometers, it was easy to procure much nicer observations, and to detect even the finer modifications of corpuscular action. But to include the usual range of temperature, it was necessary to draw the stem to an immoderate length. The attempt to remedy this inconvenience led to the construction of the first kind of *differential thermometer*. The main object was evidently attained, if the mercury should always be made to start from some given point. The tube was, therefore, left open, and a cap adapted to the top containing a surplus portion of the fluid. When the thermometer was kept inverted, this mercury closed round

the orifice; and joined the thread in the stem, as in fig. 17, Plate XCVI. But when the instrument was reversed, the excluded fluid instantly separated, and sunk into the cavity under the top of the tube, as in fig. 16. In this situation, the descent of the mercurial thread in the stem marked the depression of temperature.

Meteor-
ology.

A differential thermometer of this construction was used for three or four years, in a variety of experiments, without ever failing. But an open thermometer must be liable to some uncertainty, and unavoidably subject to a continual deterioration. The loose mercury will undergo a slow oxydation, while the bore of the tube is apt to be soiled and tarnished by the insensible introduction of moisture. Such an instrument, however, is well adapted for many researches.

In the beginning of the year 1795, another form of the differential thermometer was devised, which, Its Simplest Form.

from its simplicity, its delicacy, and extensive application, has contributed essentially to the progress of physical and chemical science. This instrument is now so generally known, that a few remarks on its general construction will be here judged sufficient. The *differential thermometer* is a modification of the air thermometer, but susceptible of the impressions of heat only, and exempt altogether from the influence of the variations of atmospheric pressure. The tube to which the scale is applied has a bore of equal calibre, from the 50th to the 15th part of an inch wide, the other branch being commonly wider; the terminating balls are not less than four-tenths of an inch in diameter, and seldom exceeding an inch and a half. A glass tube, terminated by a ball containing air, is joined hermetically, or by the flame of a lamp, to another longer tube, terminated by a similar ball containing air also, but including a small portion of some coloured liquid. The tubes are then bent, generally into a recurved or double stem like the letter U, and the liquid is adjusted to the proper height, by making bubbles of air pass from the one ball to the other, from the little enlargement of the bore left at the junction of the tubes. If both balls have the same temperature, the liquid must evidently remain stationary, but if the ball of the shorter tube be warmed, the air, expanding and exerting more elasticity, will depress the liquid in the stem; or if this ball be cooled, the air, by its contraction, allows the liquid to ascend, from the superior elasticity of the air contained in the opposite ball. The fall or rise of the liquid will, therefore, mark the excess of heat or cold in the adjacent ball, and the space through which it moves will measure the precise difference of temperature.*

Alcohol and other volatile fluids were avoided in filling the tube, lest their vapour should affect Its progressive Improvement.

* It is not difficult to compute, in general, the size of the scale of the differential thermometer. Let the diameters of the two balls be expressed in inches by a and b , the diameter of the bore of the tube being denoted by d , and the measure of a sexagesimal degree by x . The capacities of those balls, π representing the ratio of the circumference to the diameter of a circle, would hence be $\frac{\pi a^3}{6}$ and $\frac{\pi b^3}{6}$; and the portion of liquid raised through the space x would be $\frac{\pi d^2 x}{4}$. Consequently the opposite elasticities exerted are $\frac{3d^2 x}{2a^3}$ and $\frac{3d^2 x}{2b^3}$, or expressed by the altitudes of a column of sulphuric acid, of which 220 inches may be reckoned equiva-

Meteorology. unequally the elasticity of the air contained in the balls, and thus disturb the accuracy of the indication. Linseed oil, tinged with alkanet root, was first used; but it was found to be sluggish in its movements, leaving along the inside of the tube a sort of trail, which sometimes collected into globules. But the great objection to this and other fixed oils was, that they did not remain at the same point of the scale, but slowly shifted their place, owing, apparently, to a partial absorption of air in one of the balls, while their orange tint was found to fade away by exposure to the light. Deliquate potash, coloured with archil, was next employed, and with tolerable success. By degrees, however, it deposited the colouring matter, and became almost limpid. Hydrogen gas, instead of common air, was then adopted for filling the balls. This mode of construction prevented the deposition of the colouring matter; but it was experienced to be troublesome, and attended with other impediments. After numerous discouraging trials, it was at last discovered, that strong sulphuric acid, tinged with carmine, fulfils every condition, remaining permanently stationary in contact with confined air, and never losing in the slightest degree its colour from the action of the strongest light. Since the year 1801, this liquid has been constantly used in the construction of the differential thermometer. When the exhibition of striking effects, rather than scrupulous accuracy, is sought for, tinged alcohol, indeed, has in a very few cases been preferred, on account of the great facility and amplitude of its motions. But in every instance, a column of liquid, terminating in the cavity of one of the balls, or in a small cylindrical reservoir under it, was preferred, and not, as proposed by some experimenters, a single drop of the liquid, which forces its way through the bore by successive starts, and is therefore liable to much uncertainty and derangement.

The differential thermometer is capable of some diversity of form. It may consist either of a single branch, pendant or horizontal, or it may be bent into two perpendicular branches, whether contiguous or placed at a short distance. Since the motion of the column in the tube is occasioned by the difference of the elasticity of the air contained in the two balls, it is not essential that those balls should be of equal dimensions, for an equipoise must obtain whenever the augmented elasticity of the air of the hotter ball is balanced by its expansion, on the one hand, and the corresponding contraction in the opposite ball, joined to the pressure of the ascending column of the sulphuric acid. In general the balls are blown to a certain degree unequal, either to suit the particular instrument, or to please the eye; but in making observations, it must be kept invariably in the position for which it was designed, whether vertical or horizontal, since the pressure of the balancing column would be affected by an obliquity.

The differential thermometer, in its pendant form, and extended to a suitable length, from one foot, perhaps, to three or four feet, may be employed with great advantage in comparing the different temperatures of adjacent strata of air near the surface of the earth, during the progress and decline of the day; and to detect the variations in a cloudy or a clear sky, and those occasioned by winds, as modified by the quality of the ground, whether naked or clothed with vegetation. But the main use of this instrument in meteorological researches arises from the various modifications of which it is susceptible. The minute changes of temperature which it marks, discover the existence and intensity of other disturbing causes. It is thus found, that fresh ploughed ground is more affected by the solar rays than a green sward, on which also the breeze has little influence.

Meteorology.
Its Different Forms.

lent to the weight of the atmosphere, they become $\frac{660d^2x}{2a^3} + \frac{660d^2x}{2b^3}$, or $\frac{330d^2x}{a^3} + \frac{330d^2x}{b^3}$, wherefore, since air expands one 250th part for each centesimal degree, $\frac{330d^2a^3x + 330d^2b^3x}{a^3b^3} + x = \frac{220}{250}$, and by reduction $x = \frac{22a^3b^3}{8250(d^2a^3 + d^2b^3) + 25a^3b^3}$. This corresponds to ten of the millesimal degrees adopted for the differential thermometer, but the length of an hundred of those degrees which may be preferred as a larger basis for the scale will be $\frac{44a^3b^3}{1650(d^2a^3 + d^2b^3) + 5a^3b^3}$. Suppose $a = \frac{9}{4}$, $b = \frac{4}{3}$, and $d = \frac{1}{35}$, of an inch: then
$$1650 \left(\frac{1}{1225} \right) \left(\frac{27}{64} + \frac{64}{27} \right) + 5 \times \frac{27}{64} \times \frac{64}{27} = \frac{1650}{1225} \times \frac{4825}{1728} + 5 = \frac{44}{3.76+5} = 5 \text{ inches.}$$
 If the balls be of equal diameters, this expression for the length of an hundred degrees in inches will become simply $\frac{44a^3}{3300a^2 + 5a}$. Thus, suppose $a = \frac{4}{5}$ and $d = \frac{1}{90}$ of an inch; then $\frac{44 \times .512}{\frac{3300}{900} + 5 \times .512} = 3.62 \text{ inches.}$ If the density of the sulphuric acid were reduced from 1.85 to 1.62, the expression for the length of ten degrees would pass into this very simple form $\frac{a^3}{756d^2 + a^3}$.

Meteor-
ology.

III. The **HYGROMETER**.^{*}—The mutable condition of the atmosphere, as it inclines to dryness or humidity, is the main source of all the variety of meteorological phenomena. The changes which it undergoes with respect to moisture have a marked influence on a very numerous class of substances, and even on the animal frame. But unfortunately those indications are always vague, and often fallacious. To ascertain the portion of humidity which a given quantity of air holds, or is capable of sustaining, is a problem of the first importance; but our advances to the constructing of an instrument fit to measure with accuracy that disposition have been extremely slow.

* Most substances of a loose and spongy texture, or possessed of an absorbent quality, are affected, though in very different degrees, by the presence of humidity. Accordingly the variations, both in weight and bulk, which absorbent bodies undergo, have been employed to indicate the disposition of the air with respect to moisture. For this reason, such substances are likewise termed *hygroscopic*; since they are always affected by the state of the ambient medium, though they may not precisely measure its degrees of humidity or dryness. But neither heat nor moisture is passively diffused, or yet shared among different bodies in equal proportions. From some experiments made by Professor Leslie, it appears that, under a like change of circumstances, 100 grains of ivory will attract from the atmosphere 7 grains of humidity; the same weight of boxwood, 11 grains; of eider down, 16; of wool, 18; and of beech, 28. Other substances, in their respective measures of absorption, exhibit still wider differences.

Hygro-
scopes.

The dry or humid state of the air is therefore discovered, from the variable weight of certain bodies exposed to its influence. Rock salt has been applied to that purpose; but potash, the muriate of lime, sulphuric acid, and most of the deliquescent substances, whether in a solid or a liquid form, act the most powerfully. Other materials of a firm or adhesive consistence manifest the same properties, though in a lower degree. Plates of slate-clay or of unglazed earthen-ware, the shavings of box or horn, paper or parchment, wool or down,—all act as hygrometers. But these substances, especially the harder kinds of them, unless they be extremely thin, receive their impressions very slowly, and hence they cannot mark with any precision the fleeting and momentary state of the ambient medium. Nor is the weight which they gain by exposure proportioned to the real dampness of the air; for the measures of their successive absorption are found to increase in a most rapid progression, as they approach to the point of absolute humidity.

But to weigh the substances with the accuracy befitting such experiments, is a very delicate and troublesome operation. Those thin bodies are liable, besides, to become in time covered with dust, which, while it must evidently augment their weight,

cannot be detached from them without injuring their slender texture. The increase of bulk which they acquire from the portion of moisture attracted into their substance, furnishes therefore a more certain and convenient indication of the state of the atmosphere. The solid vegetable and animal fibres are connected by a fine soft netting, in which the power of absorption appears chiefly to reside. Hence the presence of moisture always enlarges the breadth of such substances, without affecting in any sensible degree their length. This effect is visible in the swelling of a door by external dampness, and in the shrinking of a panel from the opposite cause. But the substances, such as paper or parchment, which have a diffuse or interlaced texture, are extended, by the absorption of humidity, almost equally in every direction. On the contrary, twisted cord and gut, being swelled by moisture, suffer a corresponding longitudinal contraction, accompanied likewise, if not confined, by some uncoiling of their fibres.

All these properties have severally been employed in the construction of hygrometers. The expansion of the thin cross sections of box or other hard wood, the elongation of the human hair or of a slice of whale-bone, and the untwisting of the wild oat, of catgut, of a cord or linen thread, and of a species of grass brought from India,—have at different times been used with various success. But the instruments so formed are either extremely dull in their motions, or if they acquire greater sensibility from the attenuation of their substance, they are likewise rendered the more subject to accidental injury and derangement; and all of them in time appear to lose insensibly their tone and proper action.

An attempt was lately made by Professor Leslie to revive the method of measuring the expansion of absorbent cohesive substances, by their enlargement of capacity when disposed into a thin shell; and, by successive steps, he carried the hygroscope thus formed to as high a state of improvement as perhaps such an imperfect instrument will admit. A piece of fine grained ivory, about an inch and quarter in length, was turned into an elongated spheroid, as thin as possible, weighing only 8 or 10 grains, but capable of containing, at its greatest expansion, about 300 grains of mercury; and the upper end, which was adapted to the body by means of a delicate screw, had a slender tube inserted, 6 or 8 inches long, and with a bore of nearly the 15th part of an inch in diameter. (See fig. 19, Plate XCVII.) The instrument being now fitted together, its elliptical shell was dipped into distilled water, or lapped round with a wet bit of linen, and after a considerable interval of time, filled with mercury to some convenient point near the bottom of the tube, where is fixed the beginning of the scale. The divisions themselves were ascertained by distinguishing the tube into spaces which correspond each of them to the thousandth part of the entire cavity, and equal to the measure of about three-tenths of a grain of mercury. The ordinary range of the

Meteor-
ology.

^{*} From *ὑγρός*, wet, or humid, and *μέτρον*, a measure. *Hygrometer* is distinguished from *Hygroscope*; the former measuring the humidity of the air, and the latter only vaguely marking its presence.

Meteor-
ology.

Peculiarity
of its Con-
tractions.

scale included about 70 of those divisions. To the upper end of the tube was adapted a small ivory cap, which allowed the penetration of air, but prevented the escape of the mercury, and thereby rendered the instrument tolerably portable.

This hygroscope was largely, though rather slowly, affected by any change in the humidity of the ambient medium. As the air became drier, it attracted a portion of moisture from the shell or bulb of ivory, which, suffering in consequence a contraction, squeezed its contained mercury so much higher in the tube. But if, on the contrary, the air inclined more to dampness, the thin bulb imbibed moisture and swelled proportionally, allowing the quicksilver to subside towards its enlarged cavity. These variations, however, were very far from corresponding with the real measures of atmospheric dryness or humidity. Near the point of extreme dampness, the alterations of the hygroscope were much augmented; but they diminished rapidly, as the mercury approached the upper part of the scale. The contraction of the ivory answering to an equal rise in the dryness of the air, was found to be six times greater at the beginning of the scale than at the seventieth hygroscopic division; and seemed in general to be inversely as the number of hygrometric degrees, reckoning from 20 below. Mr Leslie placed, therefore, another scale along the opposite side of the tube, the space between the zero and the seventieth division of the hygroscope being distinguished into 100 degrees, and corresponding to the unequal portions from the number 20 to 120 on a logarithmic line. This very singular property will be more easily conceived from the inspection of the figure. The scale might probably be extended farther by continuing the logarithmic divisions. Thus, 320 degrees by the hygrometer would answer to 108 of the hygro-scope, or to a contraction of 108 parts in a thousand in the capacity of the bulb. But at the dryness of 300, the contraction of the ivory seemed never to exceed 105.

Boxwood was likewise formed into a hygroscope, of the same shape and dimensions; but this absorbent material swells twice as much with moisture as ivory does, and therefore requires its inserted tube to be proportionally longer or wider. Its contractions are still more unequal than those of ivory. For, near the point of extreme humidity, those alterations in the capacity of the bulb appeared to be more than twenty times greater than, under like changes in the condition of the atmosphere, take place towards the upper part of the scale. The space included between the commencement and the hundred and fortieth millesimal division of the scale, might hence be marked with 100 hygrometric degrees corresponding to the decreasing portions of a logarithmic line from 5 to 105.

In noticing the rapidly declining contractions which ivory and box-wood undergo, Mr Leslie did not mean, however, to state the quantities with rigorous precision. Much time had been consumed in attempting to trace out the law of those gradations; and such experiments are rendered the more tedious, from the protracted action of the hygroscope, which often continues travelling slowly for the space of a quarter or even half an hour. This tardiness is indeed the

great defect of all instruments of that nature, and utterly disqualifies them from every sort of delicate observation.

The very large expansions which the hygroscope shows on its approach to extreme humidity, explains in a satisfactory manner the injury which furniture and pieces of cabinet-work sustain from the prevalence of dampness. On the other hand, the slight alteration which the instrument undergoes in a medium of highly dry atmosphere, seems to have led most philosophers to believe that there is an absolute term of dryness, on the distance of which from the point of extreme moisture, they have generally founded the graduation of the different hygrosopes proposed by them. This opinion, however, is far from being correct, and might give occasion to most erroneous conclusions. No bounds can be set to the actual dryness of the air, or the quantity of moisture which it is capable of holding, which, by the joint application of heat and rarefaction, may be pushed to an almost indefinite extent.

The ivory hygroscope, after being for several hours immersed in air remarkably dry, was apt of a sudden to split longitudinally. But if the bulb endured such a range of contraction, it appeared in some instances to take at least another set, or to accommodate its constitution, by imperceptible changes, to the state of the surrounding medium.

But though the bulbous hygroscope is, in extreme cases, liable to much uncertainty and some risk, it may yet be used with visible advantage, in certain peculiar situations. The very sluggishness of the instrument, when the value of its divisions has been once ascertained, fits it so much the better for indicating the mean results. After being long exposed in situations hardly accessible, it may be conveniently transported for inspection, before it can suffer any sensible change. The hygroscope could be, therefore, employed with success, to discover the degree of humidity which prevails at considerable elevations in the atmosphere. It might be likewise used, for ascertaining readily the precise condition of various goods and commodities. Thus, if the bulb were introduced, for the space perhaps of half an hour, into a bag of wool, a sack of corn, or a bale of paper, it would, on being withdrawn from their contact, mark the dryness or humidity of those very absorbent substances.

Other hygroscopic substances have at different times been proposed, which, though possessed of greater sensibility, are yet liable to the same general objections. Thus, quills, reeds, gold beaters' skin or pellicle, the skins of frogs, or the bladders of rats, were made to act like the bulbs of thermometers, and to cause, by their contraction or dilatation, as they inclined to dryness or humidity, the included quicksilver to rise or fall in rather a wide tube. These instruments, however, being subject to injury or derangement from the smallest accident, can scarcely be applied to any practical use.

The hygrosopes which depend on the elongation of the fibres are perhaps on the whole preferable. The slice of whalebone proposed by M. Deluc, and the human hair afterwards employed by M. de Saussure, are both of them sufficiently sensible to

ETEOROLOGY.

Meteor-
ology.

external impressions; but the difficulty is to determine the precise relation subsisting between those impressions and the state of the atmosphere. Humidity is not distributed in equal shares through the air and among the several absorbent substances exposed to its penetration; nor are the degrees of expansion which it communicates either uniform or proportional to its quantity. The graduation of such instruments, being thus in a great measure arbitrary, can furnish no correct data of the hygrometric state of the atmosphere. The assumption of two fixed extreme points as the basis of the scale is evidently erroneous. Air contained within a glass receiver may be rendered as damp as possible, by the copious aspersions of water on the sides; but it can never be absolutely deprived of its moisture, which adheres the more powerfully in proportion as it becomes diminished. Caustic alkalis, concentrated acids, and some of the deliquescent salts, aided by the action of heat, all render the air drier, but without being able to complete the desiccation. By the combined application of other agents, and even by mechanical pressure, the driest air can always be made to deposit some farther portion of moisture.

M. de Saussure directed all the resources of his ingenuity to correct the anomalies of the instrument which he proposed, and at last succeeded, by multiplied precautions, in rendering it as perfect, perhaps, as its nature and composition will admit. The hair-hygroscope (for it is not entitled to the name of hygrometer) certainly shows mobility; but the degrees which it marks can afford no steady or tolerably correct estimate of the dryness of the atmosphere.*

Expansion
Hygrometric.

To arrive at an accurate measure of the dryness of the air, it is necessary to pursue a different route. Steam, in whatever way it be formed, whether by the application of heat, or the diminution of atmospheric pressure, has nearly the double of the elasticity of common air, or it would, under the same compressing force, occupy about twice as much space. In uniting with that fluid, and forming vapour, it must hence communicate an expansion exactly proportional to the quantity dissolved, or to the share of moisture required for the complete saturation of the air. This principle suggested to Mr Leslie the means of constructing an accurate hygrometer, to which his researches had been early directed. Inverting a barrel-tumbler, he ground the mouth perfectly flat, and having drilled a hole through the bottom, he cemented into it a syphon-gage, or slender recurved tube, with a narrow bore, and an intermediate swell or cavity, passing through a perforated cap of lead, and holding a portion of nut oil, tinged with alkanet root. (See Fig. 6, Plate XCVI., where it is represented half the natural size.) To form the scale, he divided 4.2 inches into an hundred equal parts; so that each degree corresponded to the ten thousandth part of the air's elasticity, the whole

Meteor-
ology.

atmospheric pressure being equal to that of a column of the oil 420 inches in height. Having now spread a few drops of water over a surface of platy glass, and slipped the tumbler upon it, the included air quickly dissolved as much moisture as was sufficient for its saturation, and marked the expansion thence acquired, by forcing the oil to rise proportionally. The quantity of effect varied much, but was often very considerable, amounting, in fine weather, to 110 or 120 degrees. This little apparatus appeared to answer the purpose intended, but it was not portable, and it always required some address. It soon gave way, therefore, to other instruments, which promised to be more easily and readily managed.

As an hygrometer of this kind exhibits the actual expansion or increase of elasticity, which the air acquires from complete humifaction, it seemed calculated for indicating the variable power of a drier or a moister atmosphere in refracting the rays of light. The barometer and thermometer had long been employed to correct the quantity of refraction; but the application of an accurate hygrometer seemed no less necessary for delicate observations. An instrument of the composition now described was accordingly entrusted, in the course of the year 1791, to the late Dr Maskelyne, and deposited in the Royal Observatory of Greenwich. Other objects, however, interfered, and an investigation, which promised important results, was never prosecuted on a regular and digested plan.

This instrument might be rendered still more accurate, by combining it with the principle of the differential thermometer. Let two similar tumblers (see fig. 5, Plate XCVI., where it is contracted to about the fourth part of its size). A and B, inverted and loaded, have their mouths ground to fit a glass plate, the air contained in each of them acting by its elasticity on the column of a recurved tube, C, which connects their cavities. Slide both of these tumblers in a dry state upon their bases, dip a hair-pencil in oil, and pass it round the outside of the mouth of A, to make it quite tight; then having removed B, and spread a few drops of water over its place, slip it on the plate again. The air included in B, now absorbing moisture, will continue to expand and to press upon the liquid column, till it has become absolutely saturated. Should any change take place in the temperature of the room during this process, it can have no effect in deranging the indication of the instrument, since it must influence precisely in the same degree the elasticity of the air contained in both balls, and thus produce an exact counter-balance.

This compound instrument is adapted to various delicate physical inquiries. In the union of different substances, a certain alteration of volume, however minute, almost invariably takes place. To ascertain such changes under various circumstances greatly ex-

* From the few observations which we have yet had time to make with an instrument of this kind recently brought from Geneva, we are sorry to say, that it falls much below our expectations. Its motions are slow and irregular; and it seems to be little affected by very considerable alterations of the state of the encircling medium.

Meteorology.

tends our views of the empire of chemical affinity. For instance, a small bit of fresh charcoal introduced under one of the tumblers will mark its absorption of the air, by the consequent rising of the coloured liquid. But the tumbler being wetted over the inside, and a portion of dry, though not recent, charcoal, with a pared surface, placed within it, after the air has ceased to dilate from humifaction, if the charcoal be brought in contact with water, the liquor will again rise, and continue for some time to indicate a renewed expansion. As the water is imbibed by the charcoal, minute globules of air will appear to escape. But if the water, by its insinuation, had merely dislodged the air from the pores, there would have been no change of volume, and consequently no alteration in the height of the liquid on the scale. Those aërial globules must have, therefore, expanded as they emerged, or they had existed in a state of condensation united to the charcoal.

On the other hand, if a roll of unsized paper, linen rags, slips of wood, or saw-dust, be successively introduced under a tumbler in which a little water is easily shed, the coloured liquor will sink rapidly in proportion as the moisture is absorbed. In this case, there is an obvious diminution of volume, and an union produced between a liquid and a solid, quite analogous to chemical solution; whereas capillary action, such as the ascent of water through sand, is attended by no change whatever of the space occupied by the compound.

Another application of this instrument was to place under the tumbler separate capsules containing different substances, liquid or solid, which exert a mutual attraction. The included air in this case served as the vehicle of transfer, and a sort of distillation was supported, of a peculiar kind. The indications of this invisible process were variable, and often striking. But to enlarge on this subject would be foreign to our purpose. We have only taken the opportunity of noting a few of the results of an inquiry which was not pushed to any extent, but which deserves to be resumed, as likely to open new paths, and to unfold the more abstruse relations subsisting among different bodies.

Philosophers have long entertained very crude notions respecting the union of moisture with air, and the different circumstances which regulate or influence the process of evaporation. Dr Halley supposed that fire, uniting with the particles of water, communicates a vesicular constitution, which enables them to rise and spread through the atmosphere. A similar idea was entertained by Leibnitz, and was extended still farther by Musschenbroek and Desaguliers. Kratzenstein adopted the vesicular system in 1743, and endeavoured to calculate the attenuation of the fluid which should produce the requisite buoyancy. Hamberger, in 1750, advanced, however, a capital step, by rejecting that hypothesis entirely, and attributing evaporation at once to a real solution of moisture in the air. This simple theory was in the following year explained at large by Le Roi of Montpellier, and fortified by some striking arguments drawn chiefly from analogy. In pursuance of his theory, he proposed to pour ice-cold water into a deep glass, and to ascertain the dryness of the air,

by noting the depressed temperature at which the dewing or deposition of vapour began to form on the outside of the glass, or was again about to disappear. Could this method have been easily and nicely reduced to practice, it might certainly have furnished an accurate estimate of the hygrometer and state of the atmosphere.

Wallerius, in his researches, was drawn aside from the right path, by a fact first noticed by Musschenbroek, who asserted that evaporation is always more copious from a deep than from a shallow vessel; and this curious and apparently anomalous fact has been confirmed by other subsequent experiments. But he found from a series of careful observations, that the quantity of water exhaled in the same situation is exactly proportional to the extent of surface exposed. He likewise made some experiments which seemed to furnish an explication of the peculiarity remarked by Musschenbroek, though their force was not generally perceived at the time. But Richman rather darkened the subject by his strange conclusion, that the measure of evaporation depends on the difference merely between the temperature of the air and of the water, whether in excess or defect.

It was not difficult to perceive that evaporation is promoted by the application of heat, and the agitation of the aërial medium. No attempts, however, were made to determine the relation of that augmented effect to the actual velocity of the wind. But experiments on the influence which an increase of temperature exerts on the quantity of evaporation have been prosecuted with various success, by Lambert, Saussure, and Kirwan. The results thus obtained unfortunately differ very widely; and though the researches of the celebrated Naturalist of Geneva were those conducted with the most care and address, yet they seem, from the vagueness of their elements, not entitled to much confidence.

If the estimate of the causes which regulate the quantity of evaporation was unsatisfactory, still more perplexing appeared the ordinary account of the source of that depression of temperature which always accompanies the process. It was commonly referred to the operation of different concurring circumstances, among which the agitation of the air was conceived to perform the principal part. The dryness of that medium, on which we shall find the effect alone to depend, was in a great measure overlooked, or was confounded with other occasional agents. An evident confusion of ideas prevailed. The celerity of evaporation was mistaken for its intensity, and the coldness induced on the exhaling surface was viewed as the accumulated effect of a rapid dissipation of moisture. It was not perceived that in a free atmosphere, vaporization proceeds with unabated energy, while the corresponding depression of temperature must advance by a relaxing progression, since otherwise the accession of an accelerated movement might push it to any extent. A little reflection, indeed, should have convinced philosophers, that the reduced temperature caused by vaporization must, in given circumstances, have a certain limit beyond which it cannot pass. But simple as this conclusion may now appear, it had escaped the most sagacious inquirers. Even Sau-

Meteorology.

Confused ideas of the Process of Evaporation.

Vague explication of the Cold produced it.

sure, a patient and accurate experimenter, persuaded himself that, when water evaporates slowly, the cold produced is scarcely perceptible. To render this sensible, therefore, he thought it necessary to accelerate evaporation. Inserting the ball of a thermometer in a wet sponge, and attaching a cord to its stem, he whirled it briskly round his head, and thus produced a cold of 18 degrees by Fahrenheit's scale, which he considered as much greater than could be obtained by other processes. To prosecute the inquiry, he had a sort of whirling table constructed, of about five feet diameter, by means of which a thermometer with its bulb incased in wet sponge, could be made to revolve with the velocity of 40 feet in a second. This machine he was at the trouble and expence of having carried up to the summit of the Col-du-Geant, where, during a residence of several days, he performed a series of interesting and valuable experiments. It did not occur to this philosopher, that by such a contrivance he was only creating to himself a vast deal of unnecessary fatigue, and that his wet thermometer, if left simply at rest for the space of two or three minutes, would have indicated exactly the same results. By all his exertions, he merely shortened the very moderate time required for attaining its extreme limit of depression.

Such were the imperfect notions which still prevailed on the subject of evaporation, so late as the year 1796, the date of the publication of the last volume of the *Voyages dans les Alpes*. It is curious to remark, that Dr Black, in his Lectures, never mentions the dryness of the air as any way promoting evaporation, but ascribes the acceleration of the process entirely to the warmth and agitation of that medium. His friend, Dr James Hutton, whose acuteness and penetration were conspicuous, had probably studied the phenomenon more closely. "I never had a hygrometer," he says; "but I used to amuse myself in walking in the fields, by observing the temperature of the air with the thermometer, and trying its dryness by the evaporation of water. The method I pursued was this: I had a thermometer included within a glass tube, hermetically sealed; this I held in a proper situation until it acquired the temperature of the atmosphere, and then I dipped it into a little water also cooled to the same temperature. I then exposed my thermometer, with its glass case wetted to a current of air; and I examined how much the evaporation of the atmosphere, by holding the ball of the thermometer, or the end of the tube in which the ball was inclosed towards the current of air; and I examined how much the evaporation from that glass tube cooled the ball of the thermometer which was included." He then proceeds to relate some hasty and very inaccurate observations made in this way. The passage now quoted occurs in a quarto volume, published in 1792, buried in a repulsive mass of diffuse reasoning and paradoxical speculation, unsupported by any definite experiment. But Dr Hutton had evidently considered it as a conjectural hint on which he laid little stress; for he speaks immediately afterwards of our possessing accurate hygrometers, which could not be admitted if the assumption he seemed to make had been strictly true.

While such loose and imperfect notions prevailed respecting evaporation, it was expedient to review the process with attention, and analyse the several changes which accompany it. The depression of temperature which it always occasions had been hastily supposed to be proportional to the rate with which the moisture is dissipated, and to be therefore augmented by every circumstance that can accelerate this effect. But if water contained in a porous vessel expose on all sides its surface to a current of air, it will cool down to a certain point, and there its temperature will remain stationary. The rapidity of the current must no doubt hasten the term of equilibrium, but the degree of cold thus induced will be found still the same. A little reflection may discover how this takes place. It is well known that the conversion of water into steam is, in every case, attended by the absorption of the heat requisite to support a gaseous constitution. Though the humid surface has now ceased to grow colder, the dispersion of invisible vapour, and the corresponding abstraction of heat, still continue without intermission. The same medium, therefore, which transports the vapour, must also furnish the portion of heat required for its incessant formation. In fact, after the water has been once cooled down, each portion of the ambient air which comes to touch the evaporating surface must, from its contact with a substance so greatly denser than itself, be likewise cooled down to the same standard, and must hence communicate to the liquid its surplus heat, or the difference between the prior and the subsequent state of the solvent, which is proportioned to the diminution of temperature it has suffered. Every shell of air that in succession encircles the humid mass, while it absorbs, along with the moisture which it dissolves, the measure of heat to convert this into steam does at the same instant thus deposit an equal measure of its own heat, on the chill exhaling surface. The abstraction of heat by vaporization on the one hand, and its deposition on the other, at the surface of contact, are, therefore, opposite contemporaneous acts, which soon produce a mutual balance, and thereafter the resulting temperature continues without the smallest alteration. A rapid circulation of the evaporating medium may quicken the operation of those causes; but so long as it possesses the same drying quality, it cannot in any degree derange the resulting temperature. The heat deposited by the air on the humid surface becomes thus an accurate measure of the heat spent in vaporizing the portion of moisture required for the saturation of that solvent at its lowered temperature. The dryness of the air is, therefore, under all circumstances, precisely indicated, by the depression of temperature produced on a humid surface which has been exposed freely to its action.

It may insure perspicuity, however, to recapitulate the great principle on which the formation of the hygrometer depends.—When water passes into steam or vapour, it enlarges its capacity, and absorbs a very large share of heat. Any body, therefore, having a wet surface, becomes generally colder, if exposed to the access of air. But this decrease of temperature soon attains a certain limit, where it continues stationary, though the dissipation of moisture still pro-

Meteorology.
Analysis of
the Operation.

Meteorology.

ceeds with undiminished activity. The same medium which transports the vapour must hence furnish also the portion of heat required for its incessant formation. In fact, after the humid surface has been cooled, each portion of the ambient air which comes to touch it, must likewise be cooled down to the level of the dense substratum. The addition of heat at the surface of contact is thus a contemporaneous act with its subtraction by the process of vaporization; and it quickly advances to the same degree of intensity, after which a mutual balance of opposite effects is maintained, and the coldness hence induced continues unaltered. An augmented circulation of the evaporating medium may hasten the process; but while it has the same drying quality, it cannot in the least affect the depression of temperature. As soon as such an equilibrium is attained, the deposition of heat on the humid surface must become just equal to its abstraction. But this deposition is evidently proportional to the diminution of temperature, which is hence a measure of the share of heat abstracted, and therefore of the dryness of the air, or its distance from saturation.

Confirmed by Experiment.

This analysis of the process of evaporation appears so conclusive, as to banish all doubt and objection. But it was desirable to confirm the deductions of theory by an appeal to direct observation. Accordingly, on setting the hygrometer upon a table in the middle of a room, and blowing from some distance against the wet ball with a pair of bellows, which had acquired the temperature of the apartment, the instrument still indicated the same measure of dryness. The experiment was repeated more accurately on a larger scale, by exposing the hygrometer out of doors to the action of a strong and arid wind, a small screen being interposed and again removed, at short intervals of time, during which alternations no change whatever could be perceived in the quantity of the depression of temperature.

Having, therefore, ascertained the great law of evaporation, and proved that the coldness occasioned by it is not, in any degree, affected by agitation or other extraneous influence, nothing seemed wanting to construct an *Hygrometer* on just principles, but to contrive a thermometer that should mark the smallest alterations of temperature. At first Mr Leslie employed a very delicate thermometer with a short range, open at the top, where a small cap of glass or ivory was fixed, containing a small portion of surplus quicksilver. (See fig. 16 and 17, Plate XCVI.) When this thermometer was heated by the hand, till the thread of quicksilver filled the whole of the stem, and formed a little globule at the top; it was inverted as in fig. 17, and all the quicksilver united into one mass; but when it was restored, as in fig. 18, to its first position, the quicksilver fell back from the cap, and lodged about the end of the stem, leaving the bore completely filled. A cap (see fig. 1, Plate XCVI.) made of thin porous earthen-ware, nearly of the shape of a lady's thimble, but somewhat larger, and filled with water, was exposed to the air, while the thermometer lay beside it in a horizontal position. After a few minutes, the thermometer was lifted up and plunged vertically into the cup; and the thread of quicksilver, which had extended through

the whole length of the bore, being, by this change of position, cut off at the top of the tube, immediately contracted, and marked, by the space of its descent, the diminution of temperature in the liquid.

Meteorology.

The very severe winter of 1794-5 afforded Mr Leslie an opportunity of making experiments on the evaporation of ice; in the course of which, he was led to the construction of the differential thermometer, now so generally known. At first he employed it merely as an hygrometer, the one ball being always naked, and the other covered with cambric, wetted as often as occasion required. These balls were about an inch and a half in diameter, and blown to the ends of the same tube, one of them having a projecting point or aperture, which was sealed, after the branches had been bent and a portion of coloured oil introduced. The graduation of the scale was determined, by placing the instrument erect between two boxes, each containing a body of water, which encompassed one of the balls, and by noticing the rise of the oil on changing the relative temperature of the bath. An hygrometer, thus formed, was sent to the late Sir Joseph Banks, in the summer of 1795; and Mr Gilpin, clerk of the Royal Society, deposited a copy of it in their cabinet. But this model is so rude and clumsy, as hardly to recall the original. In the hands of the inventor, however, the instrument was soon improved, and reduced to a convenient and portable size. He had the satisfaction of showing an hygrometer of this construction, in January 1796, to Dr James Hutton, only a few months before the death of that very ingenious philosopher, who was delighted with seeing the application of a principle which he readily comprehended, and which his sagacity had obscurely anticipated.

But the sluggishness of the oil, and its tendency to deposit its colouring matter, on exposure to the influence of light, still opposed obstacles to the perfection of this hygrometer. These were entirely removed, however, about the year 1801, by the substitution of concentrated sulphuric acid, tinged by carmine. The most powerful and continued action of the solar beams was found to produce no change whatever on that purpurine liquid, when precluded from the access of the external air. Any improvements which have since been effected on this instrument consist chiefly in its mechanical arrangement, in the selection of the tubes, the better proportion of the balls, and the elegance and conciseness of the general shape.

The hygrometer has two distinct forms; the one *portable* and the other *stationary*. The former (see fig. 13, Plate XCVI.) having its balls in the same perpendicular line, is protected by a wooden or metallic case, and fitted for carrying in the pocket; two or three drops of pure water, from the tip of a quill or a hair pencil, being applied to the surface of the covered ball, and the instrument held exactly in a vertical position whenever it is used. The latter form (see fig. 12) is susceptible of rather greater accuracy, having its balls bent opposite ways at the same height. In some instances, it is preferable to retain merely the simplest form of the differential thermometer, the vertical stems being more distant, and the balls not reflected. In both these constructions, the

Its Construction.

Meteor-
ology.

two balls, since they occupy the same level, cannot be affected in the smallest degree, by the unequal temperatures of the different strata of air in a close heated room. After the covered ball has been wetted, the instrument will continue to perform unimpaired, for the space, perhaps, of two or three hours. The addition of a few drops of water will then restore its action. But the hygrometer may be made to supply itself with moisture. It is only wanted to pass some fibres of floss-silk close over the humid ball, and immerse them at the distance of a few inches in a tall glass decanter, full of water, with a stopper which leaves open a small projecting lip.

The hygrometer has its opposite balls made to exhibit nearly the same colour and opacity, in order to exclude the admixture of photometrical influence, or prevent any derangement which the unequal action of light might otherwise occasion. The naked ball is blown of red, green, or blue glass, and the papered one is externally covered with thin silk, of rather a fainter shade, as it takes a deeper tint when moistened.

Its Theory
completed

The theory which we have given of the hygrometer, corroborated by its accurate performance, might appear complete in every part. But the progress of science commonly detects the existence of some collateral causes which come to mingle their influence with the action of the great dominating principles. In our explication of the hygrometer, we stated that the same air which abstracts moisture, and consequently the portion of heat necessary to convert it into the gaseous form, must likewise communicate to the wet ball another portion of heat equal to its depression of temperature, which is hence maintained at a constant point. This analysis, however, involves the supposition that the air conveys heat from bodies, merely by its actual transfer. But having discovered that air transmits a certain share, at least, of the heat by a sort of pulsation, or internal tremor, depending on the quality of the surface from which the impression originates; it was requisite to examine anew the process of evaporation. The effect cannot be produced solely, by the quickened recession of the contiguous portions of the ambient medium. The conterminous air must communicate heat to the humid surface also by pulsation; and hence the balance of temperature would be liable to incidental variations, if moisture, with its embodied heat, were not likewise abstracted by some corresponding process. And such is the harmonious adaptation of these elements: The discharge of vapour appears to be subject precisely to the same conditions as the emission of heat, and in both cases the proximity of a vitreous or a metallic surface produces effects which are entirely similar. Let two pieces of thin mirror-glass, or what is called Dutch plate, be selected, about four inches and a half square; and having applied a smooth coat of tinfoil, four inches square, to one of these, cover them both with a layer of the thinnest goldbeater's skin, which will adhere closely on being wetted; and after it has again become dry, cut it on each into an exact square of four inches and a quarter: Now place the two glass plates horizontally in the opposite scales of a fine balance, and adjust them to an exact counter-

poise: then, with a hair pencil, spread two grains of water over the surface of each pellicle: in a few seconds, the plate which is coated with tinfoil will preponderate, and after the former has lost all its moisture, this will be found to retain still three-tenths of a grain. The proximity of the subjacent metal to the humid surface, therefore, impedes the process of evaporation, in the ratio of 17 to 20; the very same as, in like circumstances, had been ascertained to be the retardation of the efflux of heat. From this and other experiments, we learn, that some constant portion from a humid surface is always abstracted by the pulsation of the aerial medium. The steam exhaled, in uniting with the air, communicates to this elastic fluid a sudden dilatation, which will continue to propagate itself in successive waves.

In farther illustration of this matter, cover with a thin pellicle of goldbeater's skin, both the balls of the *pyroscope*, or that form of the differential thermometer which has one ball naked, and the other enamelled with gold or silver, and wet them equally. The coloured liquid will remain for several minutes stationary at the beginning of the scale, and will then mount slowly, perhaps 10 or 15 degrees. Evaporation had, therefore, produced the same cold or depression of temperature upon the surface of the metal as upon that of the glass; from the glass, however, it was more copious than from the metal, having left the former dry, while the latter still exhaled some portion of moisture. But this action soon ceased, and the liquid fell back to its former level. On applying another pellicle, the liquid continued longer stationary, and rose only about five degrees. With repeated pellicles a difference was perceptible in the time of drying the two balls, till the thickness amounted to the 600th part of an inch.

The method employed for the graduation of the hygrometer is not only very convenient, but susceptible of great accuracy. The instrument, with a temporary scale affixed to it, is introduced into a magazine of dry air, and compared with a standard then put in action. To procure the dryness of the included medium, a flat saucer of thirteen inches in diameter, and holding a body, about half an inch deep, of concentrated sulphuric acid, and set on a ground plate of glass or metal, is covered by a very large inverted receiver, containing more than 1500 cubic inches of air, and having at the top an opening of three inches wide, on which rests a smaller plate, with two or three hooks projecting down from it. The scale of the standard instrument was determined, by suspending beside it under the receiver two delicate thermometers, one of which had its bulb coated with several folds of wet tissue paper. The descent of the coloured liquid of the hygrometer, corresponding to the difference of ten centesimal degrees of the parallel thermometers, was hence computed, and this length afterwards divided into an hundred equal parts, to form the standard degrees. To graduate any other instrument, it was only requisite to attach a scale of inches, and mark the simultaneous measures, when a steady equilibrium had at last obtained. The space of half an hour is generally sufficient to bring this about. A simple pro-

Meteorology.

portion, therefore, discovers the length answering to an hundred millesimal degrees, from which the subdivisions of each particular scale are derived.

The condition of the atmosphere with respect to dryness is extremely variable. In our climate, the hygrometer will, during winter, mark from 5 to 25 degrees; but, in the summer months, it will generally range between 15 and 55 degrees, and may even rise, on some particular days, as high as 80 or 90 degrees. On the continent of Europe, it maintains a much greater elevation; and in Upper India it has frequently stood at 160 degrees.

When the indication of the hygrometer does not exceed 15 degrees, we are directed by our feelings to call the air damp; from 30 to 40 degrees we begin to reckon it dry; from 50 to 60 degrees we should account it very dry; and from 70 degrees upwards, we might consider it as intensely dry. A room is not comfortable, or perhaps wholesome, if it has less than 30 degrees of dryness; but the atmosphere of a warm occupied apartment will commonly produce an effect of upwards of 50 degrees.

Its Performance during Frost.

But this hygrometer, will perform its office even if it be exposed to frost. The moisture spreads over the surface, and imbibed into the coat of the papered ball, will first cool a few degrees below the freezing point, and then congeal quickly into a solid compound mass. The moment in which congelation begins, a portion of heat liberated in that act brings the ball back to the temperature of freezing, and the coloured liquor, in proportion to the coldness of the external air, starts up in the opposite stem, where it remains at the same height, till the process of consolidation is completed. After the icy crust has been formed, evaporation again goes regularly forward; and if new portions of water be applied, the ice will, from the union of those repeated films, acquire a thickness sufficient to last for several days. The temperature of the frozen coat becomes lowered in proportion to the dryness of the atmosphere. The measure of heat deposited on the chill surface by the contact of the ambient air is then counterbalanced by the two distinct, though conjoined measures of heat, abstracted in the successive acts of converting the exterior film of ice into water, and this water into steam; which transformations that minute portion must undergo, before it can unite with its gaseous solvent. But the heat required for the melting of ice being about the seventh part of what is consumed in the vaporization of water, it follows that the hygrometer, when the surface of its sentient ball has become frozen, will, in like circumstances, sink more than before by one degree in seven. This inference is entirely confirmed by observation. Suppose, in frosty weather, the hygrometer, placed on the outside of the window, to stand at 28 degrees; it may continue for some considerable time at that point, until the congelation of its humidity commences: but after this change has been effected, and the equilibrium again restored, the instrument will now mark 32 degrees.

Estimate of the Hygrometer during Frost.

The theory of this hygrometer will enable us to determine not only the relative, but even the absolute dryness of the air, or the quantity of moisture which it can absorb, by comparing the capacity of

Meteorology.

that solvent with the measure of heat required to convert a given portion of water into steam. To discover the capacity of air is, however, a problem of great difficulty, and it has not, perhaps, even yet been ascertained with much precision. It was formerly estimated, we are convinced, by far too high. Thus, Dr Crawford made it to be 1.85 times, or nearly double that of water. But from several concurring observations, we should reckon the capacity of air to be only three-tenth parts of that of water. But 600 centesimal degrees, or 6000 on the millesimal scale, being consumed in the vaporization of water, this measure of heat would prove sufficient to raise an equal mass of air 20,000 millesimal degrees, or those 6000 degrees augmented in the ratio of 10 to 3. Now, at the state of equilibrium, the quantity of heat that each portion of the aerial medium deposits in touching the chill exhaling surface, or what answers to the depression of temperature which it suffers from this contact, must, as we have seen, be exactly equal to the opposite measure of heat abstracted by it in dissolving its corresponding share of moisture. Wherefore, at the temperature of the wet ball, atmospheric air would take up moisture amounting to the 20,000th part of its weight, for each degree marked by the hygrometer. Thus, supposing the hygrometer to mark 50 degrees, the air would then require humidity equal to the 320th part of its weight for saturation at its reduced temperature. When the papered ball of the hygrometer is frozen, the degrees of this instrument must have their value increased by one-seventh, so that each of them will now correspond to an absorption of moisture equal to the 17,000th part of the weight of the air.

But the value of those degrees becomes augmented in a much higher proportion, if the hygrometer be immersed in hydrogen gas. This very dilute medium appears to have about eight times the capacity of common air, and the quantity of heat which, under similar circumstances, it will deposit on the evaporating surface, must likewise, from the same principle of mutual balance, be eight times greater, and consequently, each hygrometric degree will indicate an absorption of moisture equal in weight to the 750th part of the solvent. The energy of hydrogen gas is therefore scarcely less remarkable in dissolving moisture than in containing heat. Confined with a powerful absorbent substance, while common air marks 80 degrees of dryness, hydrogen gas will indicate 70. This gas must, in similar circumstances, therefore, hold in solution seven times as much moisture as the atmospheric medium.

To discover the precise law by which equal additions of heat augment the dryness of air, or its power to retain moisture, is a problem of great delicacy and importance. Two different modes were employed in that investigation, but which led to the same results. The one was, in a large close room, to bring an hygrometer, conjoined with a thermometer, successively near to a stove intensely heated, and to note the simultaneous indications of both instruments; or to employ two nice thermometers, placed beside each other, and having their bulbs covered respectively with dry and with wet cambric. By taking the mean of numerous observations, and inter-

Meteorology.

polating the intermediate quantities, the law of aqueous solution in air was laboriously traced. But the other method of investigation appeared better adapted for the higher temperatures. A thin hollow ball of tin, four inches in diameter, and having a very small neck, was neatly covered with linen; and, being filled with water nearly boiling, and a thermometer inserted, it was hung likewise in a spacious close room, and the rate of its cooling carefully marked. The experiment was next repeated, by suspending it to the end of a fine beam, and wetting with a hair pencil the surface of the linen, till brought in exact equipoise to some given weight in the opposite scale; ten grains being now taken out, the humid ball was allowed to rest against the point of a tapered glass tube, and the interval of time, with the corresponding diminution of temperature, observed, when it rose again to the position of equilibrium. The same operation was successively renewed; but, as the rapidity of the evaporation declined, five, and afterwards two, grains only were, at each trial, withdrawn from the scale. From such a series of facts, it was easy to estimate the quantities of moisture which the same air will dissolve at different temperatures, and also the corresponding measures of heat expended in the process of solution.

By connecting the range of observations, it would appear, that air has its dryness doubled at each rise of temperature, answering to 15 centesimal degrees. Thus, at the freezing point, air is capable of holding a portion of moisture represented by 100 degrees of the hygrometer; at the temperature of 15 centigrade, it could contain 200 such parts; at that of 30, it might dissolve 400; and, at 45 on the same scale, 800. Or, if we reckon by Fahrenheit's divisions, air absolutely humid holds, at the limit of congelation, the hundred and sixtieth part of its weight of moisture; at the temperature of 59 degrees, the eightieth part; at that of 86 degrees, the fortieth part; at that of 113 degrees, the twentieth part; and at that of 140 degrees, the tenth part. While the temperature, therefore, advances uniformly in arithmetical progression, the dissolving power which this communicates to the air, mounts with the accelerating rapidity of a geometrical series.

Temperature of saturation.

It hence follows, that, whatever be the actual condition of a mass of air, there must always exist some temperature at which it would become perfectly damp, as M. Leroi had first advanced. Nor is it difficult, from what has been already stated, to determine this *dewing point* in any given case. Thus, suppose the hygrometer to mark 52, while its wet ball has a temperature of 20 centesimal degrees or 68 by Fahrenheit; the dissolving power of air at this temperature being 252, its distance from absolute humidity will therefore be 200, which is the measure of solution answering to 15 centesimal degrees or 59 by Fahrenheit. The same air would consequently, at the depressed temperature of 59 degrees, shrink into a state of absolute saturation; and if cooled lower, it would even deposite a portion of its combined moisture, losing the eightieth part of its weight at the verge of freezing.

Annexed is a small table of the solvent power of air, from the temperature of 15 centesimal degrees

below zero to 44 above it, or from -5° of Fahrenheit's scale to $111^{\circ}.2$.

Meteorology.

QUANTITIES of MOISTURE dissolved in Atmospheric Air at different Temperatures by the Centesimal Scale.

These temperatures, and the corresponding quantities of moisture dissolved, may be represented by the abscissæ and ordinates of the logarithmic curve, as in fig. 8, Plate XCVII., where some of the principal terms are marked.

The influence of warmth in augmenting the dryness of the air, or its disposition to absorb moisture, affords also the most satisfactory explication of the singular fact already noticed. If two equal surfaces of water be exposed in the same situation, the one in a shallow, and the other in a deep vessel of metal or porcelain; the latter is always found, after a certain interval of time, to have suffered contrary to what we might expect, more waste by evaporation than the former. Amidst all the changes that happen in the condition of the ambient medium, the shallow pan must necessarily receive more completely than the deeper vessel, the chilling impressions of evaporation, since it exposes a smaller extent of dry surface to be partly heated up again by the contact of the air. The larger mass being, therefore, kept invariably warmer than the other, must in consequence support a more copious exhalation.

From the principles which have been explained, it likewise results that the hygrometer does not indicate the actual dryness of the air, but only the dryness which it retains, after being reduced to the temperature of the humid ball. The real condition of the medium, however, could easily be determined, from the gradations already ascertained in the power of solution. Suppose, for example, that the hygrometer should mark 42 degrees, while the thermometer stands at 16 centigrade; the moist surface has therefore the temperature of 11.8 centigrade, at which the dissolving energy is less by 37 degrees than at 16 centigrade; and hence the total dryness of the air, at its former temperature, amounted to 79 degrees. The following table will greatly facilitate such reductions. It is computed for as wide a range of dryness and temperature as will probably occur in any climate.

Quantity of
Moisture
in the
Air.

We may compute that a cubic mass of air 40 inches every way, or a hule more than the standard of French measures, and of the ordinary density, weighs 20,000 grains. The table now given exhibits, therefore, in grains, the weight of moisture which a metrical cube of air is capable of holding at different temperatures. Thus, at 20°, which corresponds to 68° of Fahrenheit, this body of air could retain 252 grains of humidity. But if a larger scale be preferred, the same numbers will express, in pounds Troy, the quantity of water required to saturate a perfectly dry mass of air constituting a cube of twenty yards in every dimension.

It is remarkable how small a portion of the aqueous element is at any time suspended in the atmosphere. Reckoning the mean temperature over the surface of the globe to be 19 centesimal degrees, the air could only hold 210.6 parts of humidity for 20,000 times its whole weight; but this weight is nearly the same as that of a column of water of 400 inches in altitude; and hence, if the atmosphere, from a state of absolute dampness, were to pass into that of extreme dryness, and discharge the whole of its watery store, it would form a sheet of 4.812 inches, or somewhat less than 5 inches in depth. To furnish a sufficient supply of rain, the air must therefore undergo very frequent changes from dryness to humidity in the course of the year.

Determined
by Experi-
ment.

But it was requisite to subject theory to the test of accurate experiment. For this purpose, a globe or glass balloon was procured, of very large dimensions, containing nearly 4000 cubic inches, terminated by a neck of about three inches wide, having its mouth ground flat. The balloon was supported from the floor by a light circular stand or rim, and a round piece of plate glass perforated through the centre by a hole of about the twentieth part of an inch in diameter, through which passed a slender silver wire suspended from the end of a fine beam placed on the table. This wire was fastened to the top of the scale of a delicate hygrometer, from the lower part of which hung a bit of wet paper nearly three inches in diameter. The whole was balanced

by a counterpoise in the opposite scale, so that the instrument occupied the middle of the balloon. As the moisture gradually evaporated from the wet ball of the hygrometer, and still more from the larger surface of the paper attached below it, a loss of weight became visible, while the ascent of the coloured liquid in its tube indicated the corresponding diminution of the dryness of the included air. The progress of humefaction was observed from 50 to 10 degrees of the hygrometer, after each successive grain of water, amounting in all to five, had exhaled and dispersed itself through the medium. Having rectified the hygrometric degrees according to the principle already explained, it was easy to compare them with the weight of the whole mass of air contained within the balloon. The conclusions were, perhaps, as satisfactory as such a nice and fugacious inquiry will admit: and if they be not absolutely correct, they must, at least, approximate very nearly to the truth. It would be superfluous, however, to engage in the details of the experiment, and of the calculations drawn from them; especially as it is intended to repeat the operation under more favourable circumstances, and with every precaution for assisting the equable dispersion of the moisture through the encircling medium.

The table given above is in strictness applicable to air only of the ordinary density. Since this fluid has its capacity for heat enlarged by rarefaction, the same depression of temperature must intimate a proportional augmentation of dryness. Thus, for air at the elevation of three miles and a half, and consequently twice as rare as at the surface, it would be requisite to add the sixteenth part to the numbers in the first column. For the lower altitudes, the correction will be, to multiply those numbers by triple the height in feet, and cut off six decimal places. Thus, suppose, while the thermometer stood at 28 centesimal degrees, that the hygrometer marked 110° on the plains of Mexico, at the elevation of 8000 feet above the level of the sea; then $3 \times 8000 \times 255 = 6120000$, which, being divided by a million, gives 6 to be added to 255, increasing the actual

Modification
of the Table.

Meteor-
ology.

dryness to 261°. In most cases, therefore, this modification may be neglected.

But, in estimating the distance of the point of saturation in rarefied air, a greater correction will be required. The solvent power of that medium is extended about 50 hygrometric degrees, each time it has its rarefaction doubled. Hence, it may be calculated, that our atmosphere would at the same temperature become a degree drier for every 360 feet of ascent. Thus, on the preceding supposition, the air on the plain of Mexico would have its distance from the point of saturation enlarged 22½ degrees, its whole range being thus 283½ degrees.

Different
Applications
of the Hy-
grometer.

If the papered ball of an hygrometer be suffered to become dry, the instrument, even in that state, will mark, though for a short time only, the different condition of the media into which it is transported. Thus, the air of a room being supposed to have 50 degrees of dryness, on carrying the quiescent hygrometer into another apartment of 70 degrees, the column of liquor will fall near 20 degrees, from the renewed evaporation of that portion of moisture which had still adhered to the coats of paper. But if the same instrument were carried into an apartment of only 30 degrees of dryness, the coloured liquor would actually rise near 20 degrees above the beginning of the scale, the paper now attracting the excess of humidity from the air. This vapour, in combining with it, passes into the state of water, and therefore evolves a corresponding share of heat. The equilibrium, however, unless the coats of paper have a considerable thickness, is again restored in a very few minutes.

Those changes are most readily perceived, on immersing the quiescent hygrometer alternately in two receivers containing air drier and damper than that of the room. If a pyroscope, having both its balls covered with goldbeater's skin, be treated in the same way, it will indicate an effect, though momentary indeed, of a similar kind: For, in air which is drier, the pellicle of the naked ball will throw off its moisture more freely than that of the gilt ball; and in damper air it will, on the contrary, imbibe the surplus humidity with greater eagerness; thus losing some portion of heat in the one process, and gaining a minute accession in the other. The quantity of moisture concerned in producing such fleeting alterations may not exceed the thousandth part of a grain.

If a large receiver, having a delicate hygrometer suspended within it, be placed on a brass plate and over a metal cup containing some water; the included air will, from the solution of the moisture, become gradually damper, and this progressive change is marked by the instrument. Yet the mass of air will never reach its term of absolute humidity, and before the hygrometer points at five degrees, the inside of the receiver appears covered with dew. While the humifying process, therefore, still goes on, the close attraction of the glass continually robs the contiguous air of a portion of its moisture; so that, a kind of perpetual distillation is maintained through

the aerial medium; the vapour successively formed being again condensed on the vitreous surface. But if, instead of the receiver, there be substituted a vessel formed of polished metal, the confined air will pass through every possible degree of humidity, and the hygrometer will, after some interval, arrive at the beginning of its scale.

Meteor-
ology.

The contrasted properties of a vitreous and a metallic surface, in attracting and repelling moisture, may be shown still more easily. In clear, calm weather, let a drinking glass and a silver cup be placed empty near the ground, on the approach of evening; and as the dampness begins to prevail, the glass will become insensibly obscured, and next wetted with profuse dew, before the metal has yet betrayed any traces of humidity. The effect is, indeed, augmented by the cold pulses darted from the sky, which act more powerfully on the glass than on the metal.

The hygrometer is an instrument of the greatest utility, not only in meteorological observations, but in aiding domestic economy, in regulating many processes of art, and in directing the purchase and selection of various articles of produce. It will detect, for instance, the dampness of an apartment, and discover the condition of a magazine, of an hospital, or of a sick-ward. Most warehouses require to be kept at a certain point of dryness, which is higher or lower according to the purposes for which they are designed. The printing of linen and cotton is carried on in very dry rooms; but the operations of spinning and weaving succeed best in air which rather inclines to dampness. The manufacturer is at present entirely guided by observing the effects produced by stoves, and hence the goods are often shrivelled or otherwise injured before he can discern any alteration in the state of the medium. Wool and corn have their weight augmented sometimes as much as 10 or even 15 *per cent.* by the presence of moisture. But the condition of these commodities could be nicely and readily examined, by heaping them over a small wired cage, within which an hygrometer is placed.

Its Practical
Utility.

V. THE ATMOMETER. *—This instrument is an useful auxiliary, and might with some attention serve as a substitute, of the Hygrometer. It does not mark the mere dryness of the air, but it measures the quantity of moisture exhaled from a humid surface in a given time. The atmometer consists of a thin ball of porous earthen-ware, two or three inches in diameter, with a small neck, to which is firmly cemented a long and rather wide glass tube, bearing divisions, each of them corresponding to an internal annular section, equal to a film of liquid that would cover the outer surface of the ball to the thickness of the thousandth part of an inch. (Fig. 8, Plate XCVII.) The divisions are marked by portions of quicksilver introduced, ascertained by a simple calculation, and they are numbered downwards to the extent of 100 to 200; to the top of the tube is fitted a brass cap, having a collar of leather, and which, after the cavity has been filled with distilled water, is screwed tight.

Atmometer

* From *Ατμος*, exhalation, or vapour, and *μετρον*, a measure.

**Meteor-
ology.**

The outside of the ball being now wiped dry, the instrument is suspended out of doors, exposed to the free access of the air. In this state of action, the humidity transudes through the porous substance just as fast as it evaporates from the external surface; and this waste is measured by the corresponding descent of the water in the stem.

**Quantity of
Moisture
exhaled.**

If the atmometer had its ball perfectly screened from the agitation of wind, its indications would be proportional to the dryness of the air at the lowered temperature of the humid surface; and the quantity of evaporation every hour, as expressed in thousand parts of an inch, would, when multiplied by 20, give the hygrometric measure. For example, in this climate, the mean dryness in winter being reckoned 15°, and in summer 40°, the daily exhalation from a sheltered spot must in winter form a thickness of .018, and amount in summer to .048 decimal parts of an inch. Suppose a pool for the supply of a navigable canal exposed a surface equal to ten English acres, and that the atmometer sank 80 parts during the lapse of 24 hours; the quantity of water exhaled

in that time would be $\frac{80}{12000} \times 660 \times 66 \times 10$, or 2904 cubic feet, which corresponds to the weight of 81 tons.

**Velocity of
Wind.**

The dissipation of moisture is much accelerated by the agency of sweeping winds, the effect being sometimes augmented 5 or even 10 times. In general, this augmentation is proportional, as in the case of cooling, to the swiftness of the wind, the action of still air itself being reckoned equal to that produced by a celerity of 8 miles each hour. Hence the velocity of wind is easily computed, from a comparison of the indications of a hygrometer with an atmometer, or of a sheltered, with those of an exposed, atmometer. Thus, suppose the hygrometer to mark 40 degrees, or the column of water in a sheltered atmometer to subside at the rate of 2 divisions every hour, while in one exposed to the current, the descent is 12 divisions; then as 2 is to 10, the superadded effect of the wind, so is 8 to 40 miles, the distance through which it has travelled in that time.

**Utility of the
Atmometer.**

The atmometer is an instrument evidently of extensive application and of great utility in practice. To ascertain with accuracy and readiness the quantity of evaporation from any surface in a given time, is an important acquisition, not only in meteorology, but in agriculture, and the various arts and manufactures. The rate of exhalation from the surface of the ground is scarcely of less consequence than the fall of rain, and a knowledge of it might often direct the farmer advantageously in his operations. On the rapid dispersion of moisture depends the efficacy of drying-houses, which are too frequently constructed most unskillfully, or on very mistaken principles.

It is obvious, that though the atmometer should be exposed to the free air, it must be sheltered

from rain, which, by wetting the ball, would derange the proper action of the instrument. This could easily be done, by fixing a small canopy over it; or, in the case of drifting showers, to have a sort of shelved open screen, like Venetian blinds, turned by the wind. The only objection to this atmometer is, that it cannot be used during intense frost, since the expansion of the included water, by a sudden congelation, might burst the ball and even the tube. But the instrument could still be made to act in another way: Let it be emptied, and a certain portion of the water, measured in the stem, be spread over the outside of the ball, by successive layers, to form a coat of ice. The time is to be noted when the whole of this crust has disappeared, or, if any portion should remain, it may be deducted from the whole, and thus the hourly quantity of evaporation ascertained.

**Meteor-
ology.**

VI. PHOTOMETER.*—This instrument, which was contrived to indicate the power of illumination, by the slight elevation of temperature which it occasions, has been shortly noticed in the article CLIMATE of this Supplement. It consists of a differential thermometer, having one of its balls diaphanous, and the other coated with China ink, or rather blown of deep black enamel. (See fig. 17 and 18, Plate XCVI.) The rays which fall on the clear ball pass through it, without suffering obstruction; but those which strike the dark ball are stopt and absorbed at its surface, where, assuming a latent form, they act as heat. This heat will continue to accumulate, till its farther increase comes to be counterbalanced by an opposite dispersion, caused by the rise of temperature which the ball has come to acquire. At the point of equilibrium, therefore, the constant accessions of heat derived from the action of the incident light, are exactly equalled by the corresponding portions of it again abstracted in the subsequent process of cooling. But, in still air, the rate of cooling is, within moderate limits, proportioned to the excess of the temperature of the heated surface above that of the surrounding medium. Hence the space through which the coloured liquid sinks in the stem, will measure the momentary impressions of light or its actual intensity. To prevent any extraneous agitation of the air from accelerating the discharge of heat from the black ball, and thereby diminishing the quantity of aggregate effect, the instrument is always sheltered, and more especially out of doors, by a thin glass case. The addition of this translucent case is quite indispensable. It not only precludes all irregular action, but maintains, around the sentient part of the instrument, an atmosphere of perpetual calm. Under the same force of incident light, the temperature of the black ball must still rise to the same height above that of its encircling medium. The case will evidently have some influence to confine the heat actually received, and hence to warm up the internal air. Wherefore, corresponding to this excess, the black ball will acquire a farther elevation of temperature; but the clear ball, being immersed in the same fluid, must expe-

Construc-
tion of the
Photometer.

Theory of
its Opera-
tion.

* From *φῶς*, light, and *μετρον*, a measure.

Meteor-
ology.

rience a similar effect, which will exactly counter-balance the former. The difference of temperature between the opposite balls thus continues unaltered; and neither has the size or the shape of the case, nor the variable state of the exterior atmosphere with respect to rest or agitation, any sensible influence to derange or modify the results exhibited by this delicate instrument.

The photometer has, like the hygrometer, two general forms: The *stationary*, represented by fig. 15, and the *portable*, delineated in fig. 18. But they are both of them easily transported from one place to another. Their glass cases can be screwed off, and the former instrument, being cemented into a small slip of brass, which slides with a spring into the bottom, may be packed separately, if required, while the latter is protected by an external wooden case, in which it is carried in the pocket as safely as a pencil. This case, if screwed below, serves also as a handle to hold the photometer in a vertical position out of doors.

Its Use.

The photometer, placed in open air, exhibits distinctly the progress of illumination from the morning's dawn to the full vigour of noon, and thence its gradual decline till evening has spread her mantle; it marks the growth of light from the winter solstice to the height of summer, and its subsequent decay through the dusky shades of autumn; and it enables us to compare, with numerical accuracy, the brightness of different countries,—the brilliant sky of Italy for instance, with the murky atmosphere of Holland.

In this climate, the direct impression of the sun about midsummer amounts to about 90 degrees; but it regularly declines as his rays become more oblique. The greatest force of the solar beams with us in the depth of winter reaches only to 25 degrees. At the altitude of 17 degrees, it is already reduced to one half; and at 3 degrees above the horizon, the whole effect exceeds not one millesimal degree.

Light of the
Sun.

The quantity of indirect light reflected from the sky, though extremely fluctuating in our climate, is often very considerable. It may be estimated at 30 or 40 degrees in summer, and 10 or 15 in winter. This secondary light is most powerful, when the sky is overspread with thin fleecy clouds; it is feeblest, either when the rays are obstructed by a mass of congregated vapours, or when the atmosphere is clear and of a deep azure tint. On the lofty summits of the Alps or Andes, the photometer, screened from the sun, and only exposed to the dark hue of the broad expanse, would indicate a very small effect. During the late solar eclipse of the 7th of September 1820, the sky being completely overclouded, it showed, both before and after the passage of the moon's disc, only 12 degrees of light; but when the obscuration was the greatest, it marked not more than a single degree.

Light of the
Sky.

Various Ap-
plications of
the Photo-
meter.

The delicacy of this instrument renders it a valuable auxiliary in various scientific inquiries. It ascertains the diminution which the rays of light suffer in reflection, and during their passage through different transparent substances. By combining it with the transferrer of an air-pump, it likewise detects the comparative powers for conducting heat of the several gases, whether in their ordinary state, or when

Meteor-
ology.

variously attenuated or condensed. Hence we learn, that air expanded 256 times conducts heat nearly twice as slow, or in the ratio of 7 to 19; but that hydrogen gas transfers it with more than redoubled celerity, or in the ratio of 9 to 4. But the photometer will measure also the conducting powers of different liquids. It is only wanted to remove the case, and plunge the instrument erect in a wide metallic vessel, bright on the outside, but blackened within, containing the liquid to be examined, and exposed to the sun's rays. In this way, it was found that water which conveys heat about 30 times faster than air of the mean temperature of our climate, transmits it with still greater rapidity if warmed to a higher pitch. If the photometer, inclosed within its case, be immersed under the surface of water, the impression of the light will be much stronger than when the balls were encircled by the actual contact of this liquid. Yet will the effect be less than if the case had been surrounded externally by a body of air instead of water, which, by its powerful action in drawing off the accumulated heat, hastens the transmission of it through the internal medium, and reduces the elevation of the temperature of the black ball to nearly one-third part.

From observations made with this instrument, we likewise discover that, in the clearest and most serene sky, one-half only of the sun's light, sloping at an angle of 25°, will reach the ground; and that at an angle of 15°, the proportion is reduced to one-third; but with an obliquity of 5°, the length of track being then extended ten times, one-twentieth part only of the whole incident light can reach the surface. When the sun has approached within a degree of the horizon, and his rays now traverse a track of air equal in weight to a column of about 905 feet of water, no more than the 212th part of them can penetrate to the ground.

The photometer discovers the relative density of different artificial lights, and even contrasts their force of illumination with that of the solar rays. It may be mentioned as a curious inference, that the light emitted from the sun is 12,000 times more powerful than the flame of a wax-candle; or that, if a portion of the luminous solar matter, rather less than an inch in diameter, were transported to our planet, it would throw forth a blaze of light equal to the effect of 12,000 candles.

To compare the illumination of candles or lamps, and of the flame of coal or oil gas, the best form of the photometer, is that of fig. 15, Plate XCVI. guarded both in front and behind by a pair of thin spreading plates of mica, set parallel at the mutual interval of about half an inch. It may be sufficient to notice at present, that the flame of coal gas has more than triple the brilliancy of that of a wax-candle; but a series of experiments on this subject will be soon given to the public.

A photometer of the branched form is easily adapted to measure the diminution which light suffers in penetrating through a body of water. The scale may then be shortened, and the balls enlarged. A bottom of lead is turned to receive the instrument, with its case, which are cemented to it. Thus loaded, the photometer is suspended vertically by cross silk-

Meteor-
ology.

threads, to which a cord of some definite length is attached, terminating by a small bladder. The sky being clear, and the sun shining bright, the instrument is, by help of a long pole, stretched from the side of a boat, held a few minutes suspended about four inches below the surface of the water, and then drawn up, and the number of degrees marked. When the direct action of the solar rays amounted to 90 photometric degrees, their enfeebled influence on the instrument, while thus encompassed externally by a dense chilling body of water, was commonly found to be reduced to 32 degrees. From this point, therefore, the subsequent diminution, occasioned by the descent of the instrument, was computed. The photometer, being let down, was left to float near a quarter of an hour at the depth of perhaps three or six fathoms. On drawing it up, the diminished action of the light, occasioned by the length of oblique passage, was at once perceived.

From experiments performed in this way last summer, it follows that half of the incident light which might pass through a field of air of the ordinary density and 15½ miles of extent, would penetrate only to the perpendicular depth of 15 feet in the clearest seawater, which is, therefore, 5100 times less diaphanous than the atmospheric medium. The light is hence diminished four times for every five fathoms of vertical descent; and, consequently, the 64th part only could reach to the depth of 15 fathoms. Supposing the bottom then to consist of a clear white sand, the portion of light reflected, and sent back to the surface, would be attenuated more than 64×64 or 4096 times, and would therefore hardly be perceptible to the most acute eye. But the water of shallow lakes, though not apparently turbid, betrays a still greater opacity, inasmuch that the perpendicular light was diminished one-half, in descending only through the space of six feet in Loch Leven, or even two feet in a fine artificial sheet of water at Raith, near Kirkaldy. These results, however, are to be considered as mere approximations, the state of the weather having been very unfavourable for such experiments.

It would be easy, by a small modification, to adapt the photometer as a diaphanometer, for measuring the comparative transparency of different collections of water. The black and the clear ball might be blown larger than usual, and the instrument covered with two thin parallel cases of glass, separated by an interval of about three-eighths of an inch. The transparency of a lake, or of the sea, would be inversely as the length of passage traversed by the light, when it had suffered a proportional diminution of intensity.

VII. ÆTHRIOSCOPE.*—Such is the name of another very delicate modification of the differential thermometer, intended to measure those frigorific impressions which are showered incessantly from the distant sky. The history of this invention, and of its progressive improvement, has been given already in this *Supplement* (Art. CLIMATE). Since that time, few good observations have been added, owing to the very cloudy and

windy weather which has prevailed for almost two years. The chief object then was to render the æthrioscope more portable, in the hope of obtaining, through it, some correct information regarding the state of the atmosphere in other quarters of the globe. The upper ball is now scarcely half an inch in diameter; but to compensate for this diminution, the lower ball has a diameter of about four-fifths of an inch. The tube, which exceeds not four inches in length, has its bore contracted a little above its junction to the very short cylindrical cavity that holds the coloured liquor; this simple contrivance, augmenting greatly the capillary action, prevents the descent of the column into the ball from any sudden change of temperature, while it only retards the motion of the fluid, without affecting the accuracy of its play. Fig. 10, Plate XCVII. represents the instrument in this abridged form, and fig. 11 shows the way of packing it, the bottom being merely screwed to the top of the case. The only precaution needed, is not to shake the æthrioscope or invert it; and as it takes very little room, it may easily be carried by the traveller in his pocket. We may soon expect information, at once curious and interesting, from remote climates.

In ordinary cases, the hot or cold pulses propagated through the air only assist the energy of the transfer of the different portions of the fluid, in promoting an equilibrium of temperature. But the æthrioscope proves that those pulses are incessantly forwarding such a balance, even while the mere transfer and commixture of the medium would not contribute to the effect. In the article CLIMATE, it was shown that the rapid interchange which takes place between the higher and lower strata of the atmosphere, maintains an equal distribution in the quantity, and not in the intensity, of heat. Since air has its capacity for heat increased by rarefaction, it must, with the same igneous infusion, indicate a proportionally depressed temperature. But this inequality of temperature, resulting from the internal commotion produced by the sun's rays acting more powerfully near the surface of the earth, is partly corrected by the influence of the cold or hot pulses, which are at all times darted and in every direction, unless obstructed or absorbed by the interposition of the clouds. While the cold pulses from the upper strata of the atmosphere are constantly chilling the lower strata, the warm pulses again from below are exerted in warming the higher regions. In most cases this mutual influence, indeed, is comparatively feeble; but if the rays of the sun were withdrawn for any considerable time, a great progress would be made by such a mutual interchange of the pulsations towards an equality of temperature through the mass of atmosphere. The lowest strata would become unusually colder, while the highest regions would grow warmer, and sparkle with augmented clearness and lustre. Such are some of the effects of the long protracted nights within the Arctic Circle.

Much yet remains to be explored in the higher

Its Inverted
Form.

Construction
of the Æth-
rioscope.

* From *Æther*, which signifies at once clear, dry, and cold.

Meteor-
ology.

strata of our atmosphere. If the differential thermometer, included within the æthrioscope, had its position reversed, that instrument would become adapted to measure the hot pulses, which are, no doubt, shot incessantly upwards with various obliquity from the warmer beds incumbent over the surface of the earth. It would be most interesting to obtain the reports of both the erect and the pendant opposite æthrioscope; when carried up in the car of a balloon to the elevation of four miles. In that region of mid-air, we might expect the hot and the cold pulses, as they crossed in opposite directions, to act with nearly equal energy. The measures of those effects, compared with the simultaneous indications of the photometer, could not fail to dispel much obscurity, and to open new views of the disposition of the elements, and of the economy of nature.

Construction
of the Cy-
anometer.

VIII. CYANOMETER. *—This instrument was contrived by M. de Saussure, to measure the variable intensity of the carulean hue, which the sky assumes in different climates and elevations, according to the progress of the day or the advance of the season. It consists of 53 slips of paper of about a quarter of an inch broad, stained with the successive shades of blue, from the palest sapphire to the deepest azure, which are pasted around the circumference of a circle of pasteboard of about four inches in diameter. The colours were obtained from fine Prussian blue, diluting it with white chalk, or darkening it with a mixture of ivory black. He likewise compared those coloured spaces with the pure tints of a solution of copper in ammonia, which resemble most the soft transparent hues of the atmosphere. To represent the effect of clouds, and diffuse aqueous vapours, he dropped into that liquid a portion of very fine divided argillaceous earth, precipitated by ammonia from a solution of alum.

In observing with the cyanometer, it should be held out of doors, between the eye and the part of the heavens which is to be compared, and, with a little practice, the corresponding tint is easily distinguished.

In this way, Saussure found, that the deepest blue of the zenith on the summit of Mont Blanc, at his station on the Col du Geant, at Chamouni, and at Geneva, corresponded respectively to the shades, denoted 39, 37, 31, and 28¹. From morning till noon, the colour of the vertical sky darkened, but became lighter again as the evening advanced; and this transition was wider and more rapid in great elevations. On the Col du Geant, the tint of the horizontal air at sunrise was 5, it deepened to 11¹ at noon, but again relapsed to 5 towards night. On the 15th of July, which was a very clear day, the atmosphere at the horizon had the 11th shade; at the altitude of 10°, the 20th; at that of 20°, the 31st; at that of 30°, the 34th; at that of 40°, the 37th; and thence with any sensible variation to the zenith. Baron Humboldt, in his voyage from Coana to Cumana, found the tints of the sky to vary by the cyanometer, from

13 to 24, and again to 16, while the colour of the ocean fluctuated between 34 and 44.

Meteor-
ology.

The misfortune is, that we cannot annex any very distinct ideas to these numbers. We are not informed even of the proportions of the ingredients of the series of colours. The manner of composition likewise will modify the colorific effect; and most of the pigments, and especially the Prussian blue, not only want uniformity of tone, but are subject to great alteration. It would be quite impossible to paint with any water colours two cyanometers that should continue to agree, after being exposed for some time to the action of the air and the sun.

If an accurate method could be devised to discriminate colours, and mark their different tints with a sort of numerical precision, it would prove a valuable acquisition to philosophy and the arts. This was first attempted by the famous painter Leonardo da Vinci. Zahn proposed, in 1702, to accomplish it, by the graduating mixture of primary colours dispersed over the surface of a triangle; but he reckoned five of those colours, including *black* and *white*, with *red*, *yellow*, and *blue*. The celebrated Professor Mayer of Gottingen, after various trials, simplified the procedure in a posthumous work, published by Lichtenberg in 1775. Having distinguished each side of an equilateral triangle into 13 equal parts, he subdivided the whole space into 91 small triangles, which he painted with the successive mixtures of *vermillion*, *ultra-marine*, and *bright orpiment*. Lambert assumed three colours, *carmine*, *Prussian blue*, and *gamboge*, to cover a triangular base, upon which he erected a coloured pyramid, having *white* planted at its apex. But Dr Thomas Young, whose authority in those matters has deservedly great weight, prefers the simple triangle, and adopts *red*, *green*, and *violet* for the primary colours. Their binary combinations are *yellow*, formed by mixing red with green; *crimson*, consisting of red and violet; and *blue*, produced by blending green with violet. The difficulty, however, is to regulate the intensity of the compounds; nor can the powders be safely mixed except in a dry state, lest some chemical action should be introduced which might alter their tints. But the colours thus combined must evidently want the freshness and brilliancy of those which nature paints, or which the prism reveals.

Air, like water, is no doubt, by its constitution, a coloured fluid. The former is naturally blue, as the latter is green; but these colours acquire intensity only from the depth of the transparent mass. A small body of limpid water has the appearance of crystal, but in proportion as it accumulates, it assumes all the successive shades till it rivals the tints of the emerald and the beryl. This gradation is distinctly seen in the profound lakes of Switzerland, whose lustre is never stained by any vegetable infusion. The same series of colours emerges, on receding from our shores and approaching the vast abyss of the Atlantic Ocean. At first, the water on the shelving banks is merely translucid; at the depth

* From *Kuan*, carulean or sky-blue, and *μᾶτρον*, a measure.

Meteor-
ology.

of ten fathoms, it appears greenish, and the tint, by degrees, becomes more intense till it passes into a full green, at the depth of fifty fathoms; but beyond soundings, it darkens almost into azure.

In like manner, the blue shade of the air becomes more intense in proportion to the length of the tract of light. This we perceive in viewing distant objects, whose colours are always tinted by the deepening hues of the interjacent range of atmosphere. The remotest hills seem lost in a cærulean vesture. The mixture of aqueous vapours only diffuses a mist, which tar-nishes rather than dilutes the fine blue.

It must be observed, that no substance can disclose its inherent colour, but by a sort of internal secretion or dissection of the rays of light. The mere reflexion from the surface of a solid body could never betray its tints, for when rendered most perfect by polish, it would only, like a mirror, send back unchanged the incident beams. To detect the sub-jacent colour, it is necessary that the particles of light should at least penetrate under the surface, and after suffering a sort of chemical separation, should be again emitted. In transparent substances, whether solid or fluid, the penetration is greater, but the mode of evolving the native colours must be still the same. The atmosphere, besides dispersing internally the blue rays, likewise reflects in various proportions the white light unaltered. This fact is established by some experiments of *polarization*, which show that such simple reflexions are the most copious from the portion of the sky which is 90 degrees from the sun, and regularly decline on either side to the opposite points, where they cease altogether.

The white, or compound beam of light, suffering in its passage through the air, a continual defalcation of the blue rays, must, as it advances, assume the complementary colour, or the tints of the remaining portions of the spectrum, and therefore merge successively into yellow, orange, red, and crimson. Such, accordingly, are the graduating colours of the solar rays, as they approach to their extreme obliquity. Near sun-setting, the shadow of a pencil along a blank card appears a bright azure on a lilac ground. When a diffuse attenuated vapour reflects the incident light unaltered, the western sky, as the sun declines from his altitude, glows with the successive shades of yellow and orange, which deepen finally into a blush red. These colours again may, under certain circumstances, come to be blended with the natural blue of the atmosphere. Hence the explication of a curious phenomenon, which rarely occurs in this climate,—the existence of *green clouds*. This happens in the mornings and evenings, when a thin cloud is illuminated at once by the yellow rays of the sun and the bright azure of the upper sky, these contrasted colours producing a *green* by their mixture. For the same reason, sometimes a portion of the bright sky appears, in the finer climates, tinted with violet. This was remarked by Humboldt in his voyage to America and

Meteor-
ology.

we have had occasion to observe the same at Avignon. It was no doubt occasioned by the reddish rays of the declining sun dyeing the intense blue of the higher atmosphere.

The easiest and readiest way of ascertaining the tints of different portions of the sky, is perhaps to employ a sharp wedge of blue glass, of which the base and the parallel sides are painted black and cased with thin brass, and the slanting sides are ground to true planes and highly polished. To these angular surfaces two slides might be adapted, having each a broad slit, or intermediate opening, to permit the entrance and transmission of white light. Such rays having a greater length of passage to traverse, according to their distance from the top of the wedge, must emerge with a proportional intensity of blue. The scale would hence be determined by dividing the slides into ten or twenty equal parts, which might probably be sufficient.

To examine the orange and crimson tints which gild the east in the morning, or suffuse the western sky on the approach of evening, it would be necessary to combine a series of the complementary or accidental colours. A wedge of glass, stained of a gold-red or deep orange, might answer the purpose; or perhaps a nearer approximation would be obtained by joining two reversed wedges, one of an angle of 8 degrees, and crimson coloured, and another having only 3 degrees, but of a yellow body.

These instruments might be reduced to a very convenient size, not exceeding four inches in length, but they would require to be formed out of the same mass of glass, and exactly after the same pattern. With some skill in the execution, they could be made to unite elegance and correctness.

IX. ANEMOMETER.*—Various attempts have been made to construct an instrument that should readily indicate the force and velocity of the wind. One method was to employ a very small model of a wind-mill, and either to reckon its revolutions, or to estimate its power by the application of a weight to a conical barrel or axis. But a more direct and accurate procedure consisted in measuring the impulse of wind against a vertical plane, as intimated by the contraction of a spiral spring. All these instruments, however, act with such extreme irregularity, as scarcely ever to furnish any definite results. They are, besides, racked by incessant motion, and soon put out of order.

We may notice, however, a material improvement made in this construction of the machine, by Mr Waddel, of the Trinity-House, Leith, who, amidst other objects of useful experimental inquiry, has long directed his ingenuity to ascertain the force and velocity of the wind. A circular plate, of four inches diameter, is opposed to the blast; but instead of pushing against a spring, it presses a fine cylindrical bag, of about an inch long, and the third part of an inch diameter, filled with quicksilver, and joined tight to a vertical tube of glass, a foot or 15 inches high; but having a bore only the 20th part

Meteor-
ology.

of an inch wide. The compression of the bag caused by the impulse of the wind upon the plate, squeezes the quicksilver up into the tube, carrying with it a small steel mark, which slightly adheres to the sides of the bore. The height of the mercurial column, diminished in the ratio of the surface of the plate to the section of the bag, must evidently give the measure of the force of the wind. But, in the actual exposure of this anemometer, the quicksilver oscillates excessively, so that the extreme effects only are indicated. The instrument, however, is very sensible, and may continue to act for a long period without being impaired.

Its Improv-
ed Construc-
tion.

The direct action of the wind in supporting a column of water appears to furnish the best and simplest kind of anemometer. This principle was first employed, in 1731, by Pitot, the French engineer, in his recurved tube for estimating the force of the current of a river; and, forty years afterwards, it was applied by Dr Lind, to measure the impulse of a stream of air. With some modifications to correct, or at least to diminish, the oscillations of the liquid, this instrument is rendered quite manageable. The tube may consist of two pieces, each about a foot in height, having bores of the fiftieth and the fifth parts of an inch, the narrow piece being swelled out into a cylinder perhaps an inch wide, and two inches long, near the end where is joined hermetically to the other piece. The top of the narrow tube is bent horizontally, and cemented into the centre of a vertical circle of plate glass, of about three inches in diameter; or, instead of this plane, a hollow segment of a sphere of the same expansion, but including only 30 or 40 degrees, is substituted. The top of the wide tube is likewise bent horizontal, and drawn to a point at the same height as the minute central orifice of the cavity, and bent in the opposite direction. A portion of nut-oil, tinged by the alkanet root, had been previously introduced into the cylindrical cistern. On turning the small plate, or bason, to front the wind, a condensation, corresponding to its force, is immediately produced on the opposing surface, a small portion of air enters the orifice, and continues to press upon the oil, till this rises to form an equiponderant column in the wide tube. As the air can with difficulty penetrate through the very narrow bore, the irregular action of the blast is, in a great measure, corrected, and the oil moves rather tardily.

A scale is adapted bearing two sorts of divisions, the one indicating the impulse, and the other the velocity of the wind. Reckoning the weight of the atmosphere equivalent to a column of oil of 400 inches in altitude, this space is subdivided into 10,000 equal portions, each degree thus corresponding to the 25th part of an inch. It would hence be easy to show, that the pressure of the wind upon every square foot of surface is expressed in pounds avoirdupois, by dividing by five the number of degrees through which the oil ascends.

But we may place an adjacent line of subdivisions that shall mark the velocity of the wind in miles each

hour. Since air will rush into a vacuum, at the rate of 1350 feet in a second, it would, under a predominating pressure of the 100th part of an atmosphere, or at 100 degrees, flow with a celerity ten times less, or 135 feet in a second, which corresponds to 92 miles in an hour. Wherefore, 25 degrees of the scale of impulse would be marked by a velocity of 46, and 64 degrees by that of 23 miles an hour. The subordinate divisions could hence be easily formed.

Such are the velocities which theory would assign to the different altitudes of the columns supported by the force of the wind! But the actual resistance of fluids, owing chiefly to their detention at the obstructing surface, generally exceeds the result of calculation. In the case of water and air, the ratio of excess appears from experiment to be nearly that of 8 to 5. We may therefore modify the velocities after this proportion above stated. The relations of celerity and impulse will stand thus:

Celerity in Miles per Hour.	Impulse in 10,000th Parts of the Weight of the Atmosphere.
10	1° 9
20	7° 6
30	17° 1
40	30° 4
50	47° 5
60	68° 4
70	93°
80	121° 5

This anemometer, being furnished with a vane to make it always face the wind, might also, by an index, point out the direction. Nor is it absolutely requisite that the instrument should be exposed out of doors. The funnel, with its vane, may have a socket of bell-metal, nicely fitted to the top of a long perforated brass tube, which descends from the roof of the house, and terminates below in the recurved tube and its double scale. The impressions of the wind would thus be conveyed with great regularity and undiminished effect to the surface of the oil. Still, however, it would be impossible to avoid entirely the oscillations of the liquid column. Even the steadiest wind will be found to blow with a reciprocating force, now swelling and again relaxing, and, at certain short intervals, concentrating all its vehemence.

X. OMBROMETER,* or RAIN-GAUGE.—A very simple instrument, contrived to indicate the quantity, or rather the depth, of the rain which falls upon any spot. It is likewise named *Hyetometer*, and has been sometimes called by the barbarous compound *Pluviameter*. It is composed generally of a circular bason of tinned iron, soldered to the top of a vertical cylinder, which is contracted in some given proportion and closed below. A small float is introduced, bearing a slender rod, distinguished by the corresponding divisions. In the most ordinary con-

Meteor-
ology.

* From *ὀμβρος*, rain, and *μετρον*, a measure.

Meteor-
ology.

struction, the bason being a foot wide, the attached cylinder has $3\frac{1}{4}$ inches in diameter, and its section is consequently ten times smaller. The inches on the rod are hence marked only tenth parts.

This method of measuring the fall of rain is evidently not susceptible of much accuracy; and it would require the gauge to be very frequently visited, on account of the loss of the water by continual evaporation. The more correct ombrometers have their bason made of brass, and turned to a fine sharp edge; the rain, as it falls, runs through a small orifice into the vertical cylinder, which has only about the fourth part of the diameter, and communicates, by means of a cock, with another perpendicular tube still narrower, and consisting of glass having a scale affixed. The divisions of this scale are determined from the proportion of the joint sections of the cylinder and tube to the horizontal surface of the bason. In making an observation, the cock being turned, lets the collected water rise to the same level in the glass tube, and thus indicate its quantity, which, by another operation, is now drawn off. In the time of frost or snow, it becomes necessary to warm the instrument gently, and make the water flow.

We may suspect that the measure of the rain, hail, or snowy flakes received by the ombrometer, is not exactly proportioned to the extent of surface which it presents, for, while torrents pour down from the heavens, an eddy plays about the rim of the bason, deranging the regularity of the discharge. A bason of several feet in diameter would perhaps be preferable; or the platform of a roof could be adopted, if it were sufficiently sloped to allow the rain to collect quickly.

But the most perplexing circumstance affecting the ombrometer is, that it has been found to indicate very different quantities of rain as falling upon the very same spot, according to the different elevation at which it was placed. In general, less rain is collected in high than in low situations, even though the difference of altitude should be inconsiderable. Thus it was discovered, that, in the space of a year, while 12.1 inches only fell on the top of Westminster Abbey, 18.1 inches were collected on the roof of a house sixteen feet lower, and even 22.6 inches of rain at the ground. Similar observations have been made at the summit and near the base of hills of no great elevation. In such situations, we can hardly suppose the clouds to stretch down to the surface, or to augment the lower portion of rain. We must hence refer the copious fall near the ground to some other cause. Most of the rain which falls proceeds from drifting showers of short duration. The current moves more slowly along the surface, and allows the drops to descend as fast as they are formed. But being forced to mount a swelling eminence, and thus compressed into a narrower stream, it hurries the mass of vapour along with it, and does not suffer the free or full discharge on the summit. On both sides of the hill, an ombrometer placed near the bot-

tom indicates always a greater fall of rain than on the exposed top.

The observations furnished by this instrument are hence liable to considerable inaccuracy, unless made in an open champaign country. Thus, a register kept at Keswick gives $67\frac{1}{2}$ inches, which evidently exceeds greatly the annual fall of rain in that district; the quantity at Carlisle, not 25 miles distant, being only 20 inches. Again, the measures of rain, being 33 and $34\frac{1}{2}$ inches in the open country about Manchester and Liverpool, are found to amount to 45 and 60 inches at Lancaster and Kendal, which approach the flanks of a mountainous range. In general, twice as much rain falls on the western as on the eastern side of our island; and the average annual quantity may be reckoned at 30 inches, or it would form, if all collected, a sheet of water of that depth. According to this estimate, the whole discharge from the clouds in the course of a year, on every square mile of the surface of Great Britain, would, at a medium, be 1,944,613, or nearly two millions of tons. This gives about three thousand tons of water for each English acre.

XI. ELECTROMETER, * which detects the electrical state of the lower atmosphere. The best instrument of this kind undoubtedly is Bennet's, consisting of two slips of thick gold-leaf suspended from a knob within a small cylinder of glass, which is surmounted by a cap of brass. This may be connected with an insulated rod or wire, extending a few feet beyond the window. Electrometer.

The electrometer indicates the condition of the air only in its immediate vicinity. But when thunder storms prevail, the atmosphere becomes affected to a very considerable extent. Yet the indications of the electrometer are often capricious and evanescent. Whenever clouds are suddenly formed, or melt away, whether the air changes to dryness or humidity, the electrical equilibrium is disturbed. The observations made with the electrometer are hence of much less importance than was once expected, and have been gradually falling into neglect.

XII. DROSOMETER. †—An instrument so called was proposed by Weidler, a German professor, in 1727, to measure the quantity of dew which gathers on the surface of a body which has been exposed to the open air during the night. It consisted of a bent balance, which marked in grains the preponderance which a piece of glass of certain dimensions, laid horizontally in one of the scales, had acquired from the settling and adhesion of the globules of moisture. Drosometer

The main objection to a drosometer of such a construction is, that it would require to be protected from the action of the wind, and being thus screened, it could not receive the whole of the dew which might otherwise have been deposited. The steel beam too, from continual exposure to the weather, would soon lose its polish, and become unfit for any accurate performance. Besides, it is in general easier to measure than to weigh a portion of liquid.

* From *ἤλεκτρον*, *amber*, and *μέτρον*, *a measure*.

† From *δρόσος*, *dew*, and *μέτρον*, *a measure*.

Meteorology.

A simpler and more convenient **drosometer** could be formed on the principle of the **ombrometer**, or rain-gauge. Suppose a glass funnel, of about three inches diameter, whose interior surface is very smooth and slopes towards the centre, at an angle of 15 or 20 degrees, to be joined hermetically to a long tube, sealed at the lower end, and having an equable bore not exceeding the quarter of an inch, with an attached scale divided into portions, corresponding to the thousandth parts of an inch, on the external aperture. The only difficulty is to make the dew which gathers during the night to run down the sides of the funnel into the tube. To facilitate this descent, a coat of deliquescent salt of tartar may be spread with a hair pencil over the shallow surface, and renewed as often as occasion requires. The dew, instead of settling in minute detached globules, would then be attracted by the alkaline lye, which thus becoming dilute, would gradually flow into the narrow cavity of the tube. It would be easy at any time to make an allowance for the very small portion of liquid alkali blended with the dew.

Meteorological Registers.

Such is the complete apparatus required for keeping a meteorological register. But those instruments are not all of equal importance. The barometer, the thermometer, and the hygrometer, may be considered as indispensable. Next to them deserve to be ranked the photometer and æthrioscope, which disclose the more recondite condition of the atmosphere. The atmometer, the ombrometer, and the anemometer, besides, are of consequence, from the practical results which they furnish.

The value of any meteorological register, however, depends on the accuracy with which it is kept. The observations should be made in a place rather elevated, and exposed freely on all sides to the aspect of the sky; and they should be repeated either at equal intervals, during day and night, or at least at those hours which represent most nearly the mean state of the atmosphere. These requisites are seldom attained, and very few registers of the weather, accordingly, are entitled to much confidence.

It cannot be expected, that registers of the weather will possess much value, so long as they are kept merely as objects of curiosity. Like astronomical observations, as now conducted, they should no longer be left to the chance of individual pursuit. They would require to be unremittingly prosecuted in all variety of situations, and at the public expence. Proper sets of meteorological instruments should be placed not only in the regular Observatories, but sent to the different Forts and Light-houses, both at home and at our principal foreign stations. They might also be distributed among the ships employed in discovery, or engaged on distant voyages. The cost of providing those instruments would be comparatively trifling, and the charge incurred, by keeping registers on a regular and digested plan, might shrink to nothing in the scale of national expenditure.

The state of the barometer alone is kept with tolerable accuracy, because that instrument, being little influenced by collateral circumstances, marks nearly the same impressions over a wide extent of surface. The thermometer, again, is seldom observ-

ed at the proper hours, or in a situation sufficiently detached from the buildings and solid walls.

Meteorology..

It is customary, for the sake of convenience, to note the thermometer in the morning, at the height of the day, and again in the evening. But these three observations must evidently furnish results below the medium temperature of the whole twenty-four hours, since the accumulated warmth is reckoned but once, while the freshness partaking of the night is counted twice. It would be nearer the truth to assume the middle point between the maximum and minimum though even this cannot be deemed absolutely correct, because the heat neither mounts nor declines in an uniform progression. The hottest time of the day is generally about two o'clock, and the coldest just before sunrise. This hour of extreme descent is consequently very variable; and it would be difficult to fix the times suited for observing, unless they were more multiplied. But even fewer observations may sometimes be made to serve the purpose. In this climate, the daily average may be reckoned from eight o'clock of the morning, and the month of October is found to have nearly the mean temperature of the whole year.

The observations usually made with the hygrosopes of Deluc or Saussure cannot be regarded as affording any definite indication of the dryness of the atmosphere. It would essentially contribute to the advancement of meteorological science, if the hygrometer which we have described were introduced into general practice. This adoption cannot be very distant.

Some of the monks, in the religious houses scattered over the Continent, might find an agreeable and useful occupation in recording the state of the atmosphere. Many of these establishments are seated in lofty and romantic situations; and several of them, destined by their founders for the charitable accommodation of travellers, occupy the summits of the most elevated and inaccessible mountains. Accurate registers kept in such towering spots are peculiarly interesting.

Light-houses would, from their usual position, be well fitted for observing the force and direction of the wind, and the swell and relapse of the tide. The navigators who traverse the ocean in every latitude might, besides keeping meteorological soundings, record the variation of the needle, and examine the intensity of magnetic attraction.

To promote the science of meteorology, it would be most expedient that the various learned associations, planted in different parts of the globe, should institute inquiries into the state and internal motions of the higher strata of our atmosphere. As the ultimate results could not fail to prove advantageous to the public, the several governments might be expected to defray the moderate expence incurred in carrying this plan into effect. Light small balloons might from time to time be launched towards the most elevated regions, to detect by their flight the existence and direction of currents which now escape observation. Barometers, thermometers, hygrometers, and perhaps æthrioscopes, in compact forms, and which should register themselves, might be sent up in the car. Observers, furnished with accurate

Meteor-
ology.

and complete instruments, could likewise be dispatched occasionally to the intermediate heights in large balloons. By classing the various meteorological journals, and combining those ulterior facts, some new lights could not fail to be struck out, which would gradually reveal that simple harmony, which no doubt pervades all the apparent complication of the universal frame. Till we obtain such insight, we must content ourselves with the best explanations of the phenomena of the atmosphere, which our imperfect and limited knowledge will admit. We shall, therefore, treat in succession of the origin of winds; the generation of clouds and fogs; and their precipitation in the form of rain, snow, or hail. Other collateral objects will be discussed, as they present themselves to view. The narrow space which we have allotted to this discourse must confine our remarks to the more general topics.

Wind

1. WIND.—It is a curious circumstance, that in all languages the ordinary name of *air* refers to its mobility, and merely signifies *to blow*. This impulse alone of the fluid appears to have awakened our sensations; and had the atmosphere continued perfectly still, we might for ages have remained ignorant of the very existence of the fluid which we breathe.

The main cause of *wind*, or the flow of air, is undoubtedly the variable distribution of heat through the atmosphere, which incessantly affects the local density, and disturbs the equilibrium of the mass. The presence of the sun affects the surface of the terraqueous globe, which again warms and dilates the lower strata of atmosphere. The calorific action of the solar beams is greatly diminished by their obliquity; it rapidly accumulates on the land, but becomes attenuated and diffused in the waters of the ocean.

The alternation of day and night, and the annual revolution of the seasons, are hence the perpetual sources of winds. If the surface of the globe, however, had been wholly covered by the ocean, and not disparted by land and seas, those winds must have been scarcely perceptible. The daily illumination of the sun does not warm the ground to the depth of an inch; but the same quantity of illumination penetrates, though with a decreasing intensity, many fathoms into water, spreading and dividing its influence. We may reckon the tenth part of the incident light to be intercepted by a superficial stratum of the thickness of one foot; and it will hence follow, that the solar beams communicate every day a hundred times less heat to the surface of a body of water than to an expansion of level ground. The subsequent influence again of those contrasted surfaces in warming the incumbent air, must be proportionally different, though slightly modified by the portion of light reflected from the water. In a general view, the diurnal variation of temperature in the atmosphere may be considered as limited to the lowest stratum, not exceeding 2000 feet in height. Such a body of air will intercept commonly the fiftieth part of all the light which traverses it. We may hence conclude, that the change of temperature in the air, caused by the succession of day and night, is, on the whole, about thirty times less above a spacious lake than over the surrounding land.

VOL. V. PART II.

Meteor-
ology.

The current which rushes from all sides towards any heated portion of the atmosphere is easily explained and computed from the diminution of pressure which rarefaction produces at that place. The celerity of the flow is precisely the same as that of the efflux from a small aperture under the pressure of a column equivalent to that diminution, or to the difference between the weight of the warm air and of an equal volume of the exterior fluid. Thus, suppose a chimney 20 feet high, were heated up 50 centesimal degrees, or 90 on Fahrenheit's scale; the air in the flue being therefore expanded one-fifth part or four feet, would be driven upwards by the pressure of a column compensating this difference. The velocity of the discharge would hence be $8\sqrt{4}=16$ feet every second, or at the rate of about eleven miles in the hour. If a fire be kindled in an open field, it is evident that the rush of air must proceed from all sides. At the spot itself, therefore, the opposite currents will produce a counter balance, and no dominant wind can prevail. But if the warm air should cover a very wide extent of surface, its influence may be felt at a great distance, and the several converging winds may have space to blow without any mutual interference.

These views afford a complete explication of the phenomena of sea and land breezes, which are occasionally met with in every latitude, but are constantly observed near the shores of the continent, and of the larger islands within the tropics. In those sultry regions, as the day advances, a refreshing wind blows from the sea, and is succeeded by an opposite current from the interior of the land on the approach of evening, and during a great part of the night. In open seas, and especially near the equator, the thermometer scarcely varies a degree, and very seldom two degrees, by Fahrenheit's scale, in the whole course of a day. But on the land the change of temperature between the night and day, in similar situations, will rise often higher than 76 centesimal degrees, or 126 of Fahrenheit. If we, therefore, conceive a stratum of air 2000 feet in altitude, heated only to the mean difference, or three centesimal degrees, it would receive an expansion of 24 feet; whence the velocity of the wind produced would be $8\sqrt{24}=39$ feet every second, or at the rate of 26 miles in the hour. This is a very moderate estimate; but the celerity of the current must, no doubt, be diminished from the retardation which it suffers in proportion to the length of track over which it has to sweep.

During the night the lower atmosphere is colder on land than at sea, owing partly to the descent of the more elevated and colder portions of air which chill the surface of the ground, and partly to those cold pulses which are incessantly darted from every point of the azure sky. If we reckon the reduced temperature of the land only a centesimal degree and a half below the standard of the adjacent ocean, this would give 12 feet for the contraction of the vertical column of air, and, consequently, a stream would flow towards the sea with a celerity of $8\sqrt{12}=28$ feet per second, or very nearly 20 miles every hour. In general, the land breeze may be considered not so powerful as what blows from the sea.

Sea and
Land
Breezes

Meteor-
ology.

The ordinary appearances are clearly and graphically described by that very intelligent and enterprising navigator, Captain Dampier:

"These sea-breezes do commonly rise in the morning about nine o'clock, sometimes sooner, sometimes later. They first approach the shore so gently, as if they were afraid to come near it, and oftentimes they make some faint breathings, and as if not willing to offend, they make a halt, and seem ready to retire. I have waited many a time both ashore to receive the pleasure, and at sea to take the benefit of it.

"It comes in a fine, small, black curl upon the water, when as all the sea between it and the shore not yet reached by it is as smooth and even as glass in comparison; in half an hour's time after it has reached the shore it fans pretty briskly, and so increaseth gradually till twelve o'clock, then it is commonly strongest, and lasts so till two or three a very brisk gale; about twelve at noon it also veers off to sea two or three points, or more, in very fair weather. After three o'clock it begins to die away again, and gradually withdraws its force till all is spent, and about five o'clock, sooner or later, according as the weather is, it is lulled asleep, and comes no more till the next morning.

"These winds are as constantly expected as the day in their proper latitudes, and seldom fail but in the wet season. On all coasts of the main, whether in the East or West Indies, or Guinea, they rise in the morning, and withdraw towards the evening, yet capes and head-lands have the greatest benefit of them, where they are highest, rise earlier, and blow later.

"Land-breezes are as remarkable as any winds that I have yet treated of; they are quite contrary to the sea-breezes; for those blow right from the shore, but the sea-breeze right in upon the shore; and as the sea-breezes do blow in the day and rest in the night, so, on the contrary, these do blow in the night and rest in the day, and so they do alternately succeed each other. For when the sea-breezes have performed their offices of the day, by breathing on their respective coasts, they in the evening do either withdraw from the coast, or lie down to rest. Then the land-winds, whose office is to breathe in the night, moved by the same order of Divine impulse, do rouse out of their private recesses, and gently fan the air till the next morning; and then their task ends, and they leave the stage.

"There can be no proper time set when they do begin in the evening, or when they retire in the morning, for they do not keep to an hour; but they commonly spring up between six and twelve in the evening, and last till six, eight, or ten in the morning. They both come and go away again earlier or later, according to the weather, the season of the year, or some accidental cause from the land: for on some coasts they do rise earlier, blow fresher, and remain later than on other coasts, as I shall show hereafter.

"These winds blow off to sea, a greater or less distance, according as the coast lies more or less exposed to the sea-winds: for in some places we find them brisk three or four leagues off shore; in other

places not so many miles, and in some places they scarce peep without the rocks, or, if they do sometimes in very fair weather make a sally out a mile or two, they are not lasting, but suddenly vanish away, though yet there are every night as fresh land-winds ashore at those places as in any other part of the world.

"Indeed, these winds are an extraordinary blessing to those that use the sea in any part of the world within the tropics; for as the constant trade-winds do blow, there could be no sailing in these seas; but by the help of the sea and land-breezes, ships will sail 200 or 300 leagues, as particularly from Jamaica to the Lagune of Trist, in the bay of Campeachy, and then back again, all against the trade-wind.

"The seamen that sail in sloops or other small vessels in the West Indies, do know very well when they shall meet a brisk land-wind by the fogs that hang over the land before night; for it is a certain sign of a good land-wind to see a thick fog lie still and quiet, like smoke over the land, not stirring any way; and we look out for such signs when we are plying to windward. For if we see no fog over the land, the land-wind will be but faint and short that night. These signs are to be observed chiefly in fair weather: for in the wet season fogs do hang over the land all the day, and it may be neither land-wind nor sea-breeze stirring. If in the afternoon also in fair weather we see a tornado over the land, it commonly sends us forth a fresh land-wind.

"These land-winds are very cold, and though the sea-breezes are always much stronger, yet these are colder by far. The sea-breezes, indeed, are very comfortable and refreshing; for the hottest time in all the day is about nine, ten, or eleven o'clock in the morning, in the interval between both breezes: for then it is commonly calm, and then people pant for breath, especially if it is late before the sea-breeze comes, but afterwards the breeze allays the heat. However, in the evening again, after the sea-breeze is spent, it is very hot till the land-wind springs up, which is sometimes not till twelve o'clock or after."—(*Voyages*, Vol. II.)

The TRADE-WINDS, which, within the tropics, at all times constantly blow from the east, but sometimes vary their force, and decline a little to the north or the south, according to the latitude and the season—are the most remarkable of all the aërial currents, and of signal importance in navigation. These steady breezes favoured the voyage of Columbus, and conducted him to the discovery of the Mexican Archipelago. The same powerful stream afterwards drew the Portuguese from their southern course, and carried them to the shores of the Brazils. Since the character and extent of those winds have become perfectly known, the navigator reckons safely on their aid, and shapes his voyage in such a way as to reduce its performance almost to a calculation.

The cause of the trade-winds, however, is not obvious, or very easily traced. Various attempts have been made to explain the phenomenon, yet seldom on any solid or accurate principles. It would form an interesting discussion to examine the dif-

Meteor-
ology.Nature of
the Trade
Winds.

Meteor-
ology.

ferent hypotheses advanced; but we can afford room to notice, very briefly, the more considerable only of those opinions.

Des Cartes and his followers imputed the trade-winds to the inertia of the atmosphere, which they conceived to prevent this fluid from acquiring the full rotation of the earth, especially near the equator. The air being thus left behind as the globe rolled from the west, would have an apparent motion in the contrary direction, and seem to blow from the east. But it may be urged, that as passengers almost insensibly gain the celerity of the ship which carries them, so every portion of the incumbent atmosphere, though more loosely adherent to the terraqueous surface, must soon acquire the peculiar motion corresponding to the parallel of latitude. Nor would the inequality of such combined movements in the air at all disturb the order and arrangement of its general mass.

Halley's
Hypothesis.

Dr Halley gave a different explication of the origin of trade-winds, which seems very plausible, and has long been deemed quite satisfactory. This able philosopher and experienced navigator supposed, that the spot where the sun's vertical rays exert their utmost heating energy, being in the lapse of a day successively transferred from east to west round the circumference of the globe, must, as a centre of confluence, draw in its train a current of air. The current thus formed would result from the excess of the streaming from the east above that from the west; and it would therefore advance with a tardy pace, following at a distance the powerful energy of the sun. The same easterly wind might incline towards the north or the south, according as the great luminary appears to approach to the northern or the southern tropic.

But it should be observed, that the torrid zone stretches mostly over the ocean, and includes only a narrow portion of land. The heat excited in succession through that liquid track, by the diurnal passage of the sun, is hence extremely small, and hardly sufficient to produce the aspiration of the gentlest air. Nor could even this feeble current have a decided and constant direction. It would only tend towards the heated part of the surface of the ocean. In the morning, it would breathe from the west; about noon, it would become neutral, and die away; and, in the evening, it would again spring up, and flow from the east. Near midnight this current would sink into a perfect calm. The hypothesis will, therefore, not bear any strict examination. It is neither adequate to the production of such effects, nor accordant with the actual phenomena of the trade-winds. It casts a false glare over the subject, without elucidating its real bearings.

True
Theory.

The first who succeeded in taking a correct view of the question was George Hadley, in a short paper inserted in the *Philosophical Transactions* for 1735. By combining in some measure the idea of Des Cartes with the opinion of Halley, he produced a clear and simple account of the cause of trade-winds, which appears entirely consistent and free from every objection. Though the daily variation of temperature be very inconsiderable within the tropics, yet the annual accumulation of heat renders

Meteor-
ology.

the equatorial regions much warmer than the higher latitudes, and consequently maintains a perpetual current of air from either side. If those aerial motions were not modified by the figure and rotation of the globe, there would always be two opposite winds blowing directly from the north and from the south to the equator. But the stream which perhaps originates at the northern tropic, in advancing to the equator, must seem gradually to deflect towards the west, in consequence of the increasing velocity with which the successive parallels of latitude are carried eastwards. During the time this current takes to perform its journey, it is apparently transported to the west, through a space equal to the excess of the arc described by the equator above the corresponding arc traced by the tropic. The current from the southern tropic is equally bent towards the west. When both of them meet at the equator, their opposite impulsions from the north and the south are extinguished, and they flow directly west in a single united stream, and with accumulated force. The apparent motions of the different streamlets which from both hemispheres conspire to constitute the trade-wind, is represented in Fig. 18, Plate XCVII.

But it is not enough to connect the general facts; its Detail a complete theory should harmonize all the subordinate details. An easy calculation accordingly is conducted to those precise results which are commensurate and exactly congruous with the actual phenomena. The trade-wind may be reckoned to begin about the latitude of 25 degrees. At this parallel, the mean temperature is four centesimal degrees colder than immediately under the equator, which difference of heat may graduate through the atmosphere to the altitude of 10,000 feet. Wherefore the expansion of the air at the equator which draws to it a meridional wind, will amount to a column of 100 feet. The velocity of the current hence produced must be $\frac{8}{100}$, or 80 feet every second, which corresponds to 54 miles in the hour. But each point on the parallel of 24° is carried eastwards by its revolution about the earth's axis 7 miles faster every hour than on the parallel of 25°. Consequently, when the wind arrives at the parallel of 24°, it will seem to have acquired a tendency of 7 miles an hour to the west. As it reaches the successive parallels of 23°, 22°, 21°, &c. it will gain continual, though decreasing, additions to its apparent westerly course, which at the equator will have augmented to 104 miles in the hour.

In this calculation, we have made no deduction for the resistance which the streams of air must experience in sweeping over the surface of the globe, because no experiments have been made to ascertain the effect of such retardation. It is no doubt less on the ocean than on the land, and must evidently be diminished in proportion to the depth of the mass of fluid which is borne along. Still, however, this obstruction, joined to this impediment of internal motion, must be very considerable; and we may safely reduce the numbers before stated to one-third, which would give 18 miles an hour for the celerity of the primary meridional wind, and 35 miles for that of the oriental or trade-wind, resulting from the influence of the figure and rotation of the earth.

Meteor-
ology.

Our northern hemisphere presenting to the action of the solar beams a larger surface of land than the southern, is, on the whole, rather warmer. Hence the parallel of greatest heat runs not exactly through the equator, but about three degrees farther north. This circle is therefore strictly the mean path of the aggregate easterly streams of air.

But though the hottest part within the torrid zone, taking the average of a whole year, occupies the parallel of three degrees north latitude, it must to a certain extent shift its position with the seasons. In the summer months, the sun shines twice vertical upon the tropic of Cancer, and consequently raises the temperature of the northern half of the zone. During winter again, this effect is transferred to the southern half of the torrid region. In the progress of summer, therefore, the trade-wind gradually bends about a point towards the north; but as winter advances, it declines as much to the south.

Such is the character of that general wind which encircles the globe, flowing with slight deviation constantly from the east, and spreading over a zone of more than 50 degrees in breadth. It sweeps the Atlantic Ocean from the coast of Africa to Brazil, and the Pacific from Panama to the Philippine Isles and New Holland, and again the Indian seas partially from Sumatra to Zanguebar.

Monsoons.

The trade-wind undergoes an essential modification, however, where the continent stretches into the torrid zone. The sun acting more powerfully upon the land than upon the surface of the sea, the accumulated warmth is much greater, and shifts with the revolution of the seasons on either side of the equator. The centre of heat approaches in summer to the northern, and in winter to the southern tropic. Instead of the great eastern stream, those regions have two opposite periodic winds alternating towards the north and the south, and called the *monsoons*. When these winds advance to the equator, they conjoin an apparent easterly velocity; but when they recede from the equator, they carry their excess of velocity from the west. A diagonal motion results from the combined tendencies. In the Arabian and Indian seas, on the north side of the equator, the monsoon blows north-west during the summer months, from April to October; and in the opposite direction, or south-east, during the winter. But on the south side of the equator, near Java and Sumatra, the course of the monsoon is north-east in summer, and south-west in winter.

The primary winds which blow from the parallels of 25 or 30 degrees to the equator, must evidently give rise to opposite currents that flow in the higher atmosphere towards the poles. These streams, after they have travelled beyond the tropics, may descend to the surface, transporting the celerity of equatorial rotation. They will appear, therefore, to blow from the western quarter, with the excess of their previous velocity above that of the parallel which they reach. Hence a westerly breeze, of considerable force and regularity, prevails in either hemisphere above the latitude of 30 degrees. The same winds cross the Atlantic from Newfoundland to Cornwall, and traverse the Southern Ocean from the Plata to the Cape of Good Hope, and thence to New Hol-

land. Any wind which blows from the quarter inclining to the south of the west comes really from the equatorial region, and is therefore relatively warm. Such is the disposition of our westerly winds, which commonly prevail for nine months in the year.

On the same principle, a wind which blows directly from the arctic pole, and impregnated with intense cold, must, in consequence of the rotation of the globe, appear to arrive from some point to the north of the east. In passing through the first degree of latitude, it will suffer a deflection of 18 miles in the hour towards the west; in a short space, therefore, it will seem to flow with impetuous force, and almost directly from the east. Hence our easterly and north-easterly winds have a polar origin, and are always bitterly cold.

Local winds could be explained, if the different circumstances which affect them were distinctly known. The latitude and temperature of the place—its relative position—the figure and contour of the surrounding country—would all enter into the calculation. We shall content ourselves with a concise notice of some peculiar winds. The *Bize* is a cold piercing wind, which blows from the ridge of the Jura, and the frozen summits of the Pyrennees. The *Strocco* is a hot, moist, and relaxing wind, which visits Naples and the south of Italy, from the opposite shores of the Mediterranean. The *Harmattan* seems to be a cold and dry wind, of a very parching quality, which is frequent in Africa and some of the eastern countries. The *Samiel*, or *Simoom*, is a burning pestilential blast, extremely arid, which springs up at times in the vast deserts of Arabia, and rushes with tremendous fury, involving whole pillars of sand.

Local
Winds.

II. CLOUDS.—Their formation and dissolution produce all the varied train of the meteorological phenomena. The humidity suspended in the atmosphere is derived by exhalation partly from the land, but ultimately from the vast expanse of the ocean. A surface of lake, of pasture, corn-fields or forest, supports a continual evaporation, augmented only by the dryness of the air, and the rapidity of its successive contacts. Even ploughed land will supply nearly as much moisture to the exhaling fluid as an equal sheet of water. It is only when the ground has become quite parched, that it obstinately retains its latent store.

Theory of
Clouds.

If the whole of the waters, which fall from the heavens, were to return again, the evaporation from the ground might be sufficient alone to maintain the perpetual circulation. But more than one-third of all the rains and melted snows are carried by the rivers into the ocean, which must hence restore this continued waste. The commerce of land and sea is thus a necessary part of the economy of nature.

The air, in exhaling its watery store, is rendered quite damp; but it may afterwards become dry, on being transported to a warmer situation. Such is the case of the sea breeze, particularly in summer. It arrives on the shore, cold and moist; but as it advances into the interior of the continent, it grows milder and drier. The same principle accounts for the disposition of different winds in respect to humidity. At Colombo, in the island of Ceylon, as we gather from some remarks of Dr Davy, the north-

Meteor-
ology.

east monsoon, with a temperature of only 68 on Fahrenheit's scale, has yet a dryness of 75 hygrometric degrees; but the opposite monsoon, from the south-west, though at 82 by the thermometer, is so damp as to indicate scarcely 30 degrees. The cold wind, coming from the north, was rendered warmer and drier in its progress; while the hot wind, flowing from the equator, was somewhat chilled and made damper as it approached Ceylon.

Since air in mounting upwards has its capacity for heat enlarged, and becomes colder, it will hence likewise grow proportionally damper. But a continual intercourse being maintained between the lower and the higher atmosphere, the middle region must, from its chillness, be soon charged with moisture. If this tendency were to act, therefore, without control, the heavens would have been shrowded with perpetual clouds and darkness, and never could the cheering rays of the sun have visited the surface of the earth. A principle of conservation happily occurs to restrain, and finally to overpower the effect of cold, in disposing air to part with its moisture. By expansion, this fluid is made capable of holding, at the same temperature, a larger share of humidity. Each portion of air, in rising vertically, grows, from the predominance of cold, constantly damper; but after having reached a certain altitude, it again becomes gradually drier, from the influence of its wide dilatation. Every time the air has its volume doubled, it acquires an additional dryness corresponding to 50 hygrometric degrees. Hence one degree would be the effect of the rarefaction of only the 72d part. This small variation again answers to a depressed temperature of $1\frac{1}{2}$ on the centesimal scale, which, near the surface, will occasion an increase of humidity equal to the actual range of the solvent power of the air divided by 31.4. Suppose the thermometer to mark 15° centesimal at the ground, the air would, for each ascent of about 390 feet, be $\frac{200}{31.4}$, or 8 hygrometric degrees damper,

which would be reduced to 7° by the influence of dilatation. Had the temperature at the surface been as low as -25° , which answers to a solvent power of $31\frac{1}{2}$, the opposite agencies of cold and rarefaction would evidently have produced a perfect balance, and the same dryness would have continued to a moderate height.

Then Mean
Height.

It would be easy to show that d , expressing the density of the air at any altitude, and h the corresponding indication of the hygrometer, $\frac{h}{62.8} \left(\frac{1}{d} + d \right)$

will denote the increment of humidity occasioned by depressed temperature, while the corresponding decrement resulting from expansion is one degree. Hence at the pole the position of the *maximum* humidity in the atmosphere must occur at an elevation of 13,300 feet; where the density is .6, the temperature would stand at 26.7° , and the hygrometric range only 29° . Under the equator, that limit would attain a much greater altitude, and yet not rise so far above the curve of perpetual congelation. It is probable, however, that the canopy of clouds descends considerably lower, being warmed by the hot pulses

Meteor-
ology.

darted from the ground and the inferior strata of the atmosphere. We shall not err much, if we estimate the position of extreme humidity at the height of two miles at the pole, and four miles and a half under the equator, or a mile and a half beyond the limit of congelation. This range is represented in Fig. 18, Plate XC VII. running nearly parallel to the curve of perpetual congelation, but bending nearer in approaching the equatorial parts. It marks the mean height of the clouds in different latitudes, and intimates the shading into the fine ethereal expanse.

The moisture deposited by a body of air in minute globules, which remain suspended or subside slowly in the atmosphere, constitutes a *Cloud*. When it comes near us, whether it hovers on the tops of the hills, or spreads over the vallies, it receives the name of a *Fog*. The cold occasioned by the ascent, or transfer of air, may be sufficient to form thin clouds, but a more powerful and extended energy is required for the production of *Rain*. The subject has from the earliest times engaged the attention of philosophers, who have made numerous unavailing attempts to explain it. At length, the very ingenious Dr James Hutton subjected the problem to a correct analysis, and succeeded in deducing a most satisfactory solution. His fine *Theory of Rain*, which first appeared in the *Transactions of the Royal Society of Edinburgh* for the year 1787, constitutes an epoch in meteorological science. Its merits, however, have been slowly perceived by the public, because the author, full of his original conception, satisfied himself with merely sketching the general outline. But it was not enough that the operation of the principle advanced should always cause rain; it was farther requisite, that the results arising from its application should quite accord with the actual phenomena. We shall, therefore, endeavour to render this theory more definite, and more complete.

Air in cooling becomes ready, we have seen, to part with its moisture. But how is it cooled in the free atmosphere, unless by the contact or commixture of a colder portion of the same fluid? Now, the portion of the air which is chilled must in an equal degree warm the other. If, in consequence of this mutual change of condition, the former be disposed to resign its moisture, the latter is more inclined to retain it; and, consequently, if such opposite effects were balanced, there could, on the whole, be no precipitation of humidity whatever. The separation of moisture, on the mixing of two masses of damp air at different temperatures, would therefore prove, that the dissolving power of air suffers more diminution from losing part of the combined heat, than it acquires augmentation from gaining an equal measure of it; and, consequently, this power must, under equal accessions of heat, increase more slowly at first than it does afterwards, thus advancing always with accumulated celerity.

The quantity of moisture which air can hold thus increases in a much faster ratio than its temperature. This great principle in the economy of nature was traced by Dr Hutton from indirect experience. It is the simplest of the accelerating kind, and perfectly agrees with the law of solution, which the hygrometer has established. Suppose equal bulks of air in a

tion of
Clouds.

Hutton's
Theory of
Rain.

Illustrations.

Meteor-
ology.

state of saturation, and at the different temperatures of 15 and 45 centesimal degrees, were intermixed, the compound arising from such union will evidently have the mean temperature of 30°. But since, at these temperatures, the one portion held 200 parts of humidity, and the other 800, the aggregate must contain 1000 parts, or either half of it 500; at the mean or resulting temperature, however, this portion could only suspend 400 parts of humidity, and, consequently, the difference, or 100 parts, amounting to the two hundredth part of the whole weight of air, must be precipitated from the compound mass.

As another illustration, let air of 15° be mixed with air at the temperature of 35°, in three different proportions, all at the point of saturation; one part being combined with three parts, two with two, and three with one. The temperatures arising from the commixture would be 20°, 25°, and 30°; the corresponding parts of moisture precipitated from the mass being derived from the intermediate proportions of 200 and 504, are 352—317.5, or 34.5, 276—252 or 24, 352—317.5 or 34.5, and 428—400 or 28. These depositions are represented in Fig. 8, Plate XCVII. by the several intervals between the logarithmic curve and the oblique line which connects the summits of the ordinates of 15° and 35°.

In these examples we have assumed the portions of differently heated air to be quite charged with moisture before mixing; but it is only required that they should approach to the point of humidity. The effect, however, of simple commixture would, in most cases, be very small. To explain the actual phenomena, we must have recourse to the mutual operation of a chill and of a warm current, driving swiftly in opposite directions, and continually mixing and changing their conterminous surfaces. By this rapidity, a larger volume of the fluid is brought into contact in a given time. Suppose, for instance, the one current to have a temperature of 50, and the other that of 70 degrees, by Fahrenheit's scale; the blending surfaces will, therefore, assume the mean temperature of 60°. Consequently, the two streams throw together 200 and 334.2 parts of moisture, making 567.1 parts for the compound, which, at its actual temperature, can hold only 258.6 parts; the difference, or 8.6 parts, forms the measure of precipitation, corresponding to the 2325th of the whole weight of the commixed air. It would thus require a column of air 30 miles in length to furnish, over a given spot, and in the space of an hour, a deposit of moisture equal to the height of an inch. If the sum of the opposite velocities amounted to 60 miles an hour, and the intermingling influence extended but to a quarter of an inch at the grazing surfaces, there would still, on this supposition, be produced in the same time a fall of rain reaching to half an inch in altitude.

These quantities come within the limits of probability, and agree sufficiently with experience and observation. But in the higher temperatures, though the difference of the heat between the opposite strata of air should remain the same, the measure of aqueous precipitation is greatly increased. Thus, while the mixing of equal masses of air, at the temperatures of 40° and 60°, is only 6.6, that from a like

mixture at 80° and 100° amounts to 19°. This result is entirely conformable to observation, for showers are most copious during hot weather and in the tropical climates.

The quantity of moisture precipitated from the atmosphere thus depends on a variety of circumstances,—on the previous dampness of the commixed portions of the fluid,—their difference of heat,—the elevation of their mean temperature,—and the extent of the combination which takes place. When this deposition is slow, the very minute aqueous globules remain suspended, and form clouds; but if it be rapid and copious, those particles conglomerate, and produce, according to the state of the medium with regard to heat, rain, hail, or snow.

The profuse precipitation of humidity is caused by a rapid commixture of opposite strata. The action of swift contending currents in the atmosphere brings quickly into mutual contact vast fields of air over a given spot. The separation of moisture is hence proportionally copious. In temperate weather, this deposition forms rain; but, in the cold season, the aqueous globules, freezing in the mid-air into icy spiculæ, which collect in their slow descent, become converted into flakes of snow. Hail is formed under different circumstances, and generally in sudden alternations of the fine season, the drops of rain being congealed during their fall, by passing through a lower stratum of dry and cold air.

The drops of rain vary in their size perhaps from the twenty-fifth to a quarter of an inch in diameter. In parting from the clouds, they precipitate their descent till the increasing resistance opposed by the air becomes equal to their weight, when they continue to fall with an uniform velocity. This acquired or terminal velocity is therefore in the subduplicate ratio of the diameters of the aqueous globules. A thunder shower hence pours down much faster than a drizzling rain. In general, if d express the diameter of a drop in parts of an inch, the terminal velocity, according to theory, will be denoted by $78\sqrt{d}$, or if the usual correction be made for the discrepancy in fluids, it will be $67\sqrt{d}$. Thus a drop of the twenty-fifth part of an inch, in falling through the air, would only gain a celerity of $11\frac{1}{2}$ feet, and while one of a quarter of an inch would acquire a celerity of $33\frac{1}{2}$ feet. A flake of snow being perhaps nine times more expanded than water, would descend thrice as slow. But hail-stones are often of considerable dimensions, exceeding sometimes the length of an inch. They may hence fall with a velocity of 70 feet each second, or at the rate of about 50 miles in the hour. Striking the ground with such impetuous force, it is easy to conceive the extensive injury which a hail shower may occasion in the hotter climates. The destructive power of those missiles in stripping and tearing the fruits and foliage, increases besides in a faster ratio than the momentum, and may be estimated by the square of their velocity multiplied into mass. This fatal energy is hence as the fourth power of the diameter of the hail-stone.

III. OPTICAL PHENOMENA.—It remains for us to explain the general optical appearances of the sky. When the rays of the sun strike upon a

Meteor-
ology.

Velocity
the foot
of them.

Meteor-
ology.

cloud, they are copiously reflected, but partly absorbed by the minute suspended globules. In working their progress through the mass of vapour, they suffer a great diminution from the multiplied acts of absorption. The quantity of light thus finally detained depends on the density of the clouds and its thickness. But the portion which penetrates through the nebulous medium is always much less than what traverses an equal body of air. In extreme cases, perhaps, the solar beams will suffer greater defalcation by repeated repercussions within a congregated cloud, than from passing through fifty times the same extent of a clear aerial expanse. Hence such clouds always appear dark and black by their scanty transmitted light. Whiteness being produced by the copious emission of intermingled rays, can belong only to very thin clouds. The depth of shade indicates the mass of floating vapour.

Rainbows.

Owing to the excessive minuteness of the aqueous globules, the particles of light are only reflected or absorbed at their external surface, without entering them. But when they collect into large drops, the luminous pencil which strikes at a certain angle, converges by refraction to a point of the posterior surface, and after suffering one or more interior reflections, it emerges dissected into its primitive colours. Hence the glorious vision of the rainbow, which was reduced to mathematical calculation by Des Cartes, but only received its complete explication from the optical discoveries of Newton. The phenomena occur whenever the sun shines upon the falling drops of rain behind the spectator, the coloured arch being a portion of circle, whose centre is a point in the sky directly opposite to the sun. The primary or interior bow is formed by a single reflexion, and lies 45° beyond that centre; but the secondary or superior bow, produced by a double reflexion, appears with inverted tints at the distance of 56° . A ternary bow may exist, but being so extremely faint from the repeated reflexions, it is scarcely ever perceived. It hence follows, that rainbows are only visible when the altitude of the sun is below 45° and 56° . In summer, accordingly, they are not seen in this climate about the middle of the day. For the same reason, they generally appear less than a semicircle; but viewed from the top of a spire, or any lofty pinnacle, they embrace nearly the whole circumference. Lunar rainbows may be frequently observed, only the faintness of their colours makes them far less conspicuous.

Halos.

The coloured rings or *halos* which are often seen surrounding the moon and sun, are evidently occasioned by very thin vapour diffused through the atmosphere. They are supposed chiefly to encircle the moon; but, in this climate, hardly a day passes with light fleckered clouds, when at least portions of halos may not be perceived near the sun. It is only necessary to remove the glare of light which makes the delicate colours appear white. Thus, if we examine the reflexion from a smooth surface of water, we shall perceive that the sun glides the fleecy clouds with segments of beautiful coloured rings. This effect is still more distinctly seen, if the rays from a hazy or mottled sky be received upon a sheet of white paper, held before a small hole in the

Meteor-
ology.

Their Ori-
gin.

window-shutter of a dark room. But even when the sun shines from an azure firmament, circles of the richest tints may be produced by experiment. Holding a hot poker below, and a little before the small hole of the shutter, throw a few drops of water upon, and the sun will be painted on the paper like the glowing radiations of the *passion flower*. The appearance is exactly similar to what the traveller, in awakening from a short slumber, perceives, in a winter's morning, on opening his wearied eyes to a burning candle—concentric rings of violet, green, yellow, and red.

The explication formerly given of the cause of halos, even that proposed by Newton himself, is inadmissible—since it would confine them, like the rainbows, to certain definite limits, whereas they appear with every possible degree of extension. Our earliest inquiries led us to refer the origin of halos to the *deflexion* of light, or that property of the rays to bend and divide as they pass near the edge of a body. Thus the light admitted through a very narrow slit in a card, or a bit of tinfoil, spreads into bright coloured fringes. The finer also is the slit, the broader are the fringes. A similar appearance is obtained by looking at the elongated flame of a candle through the delicate fibres of a feather, or even through the streaks of grease rubbed by the finger along a piece of glass. But if a very small round hole be substituted for the slit, the fringes will change into coloured rings. Thus, if a piece of tinfoil, punctured with the point of a needle, be held close to the eye, the sun will appear through it surrounded by a halo very near his disc, but spreading more in proportion as the hole is contracted. That ingenious artist, Mr Troughton, constructed for us a slide of brass, and afterwards another of platina, perforated with a series of the finest conical holes, which were measured by his delicate micrometer. The purpose was to compare the angle subtended by the coloured ring, with the diameter of the perforation, it being inferred that an aqueous globule of the same dimension might, by the exterior deflexion of the solar rays, produce a similar halo. But our variable sky is very seldom fit for any refined optical experiment, and many delays happening to intervene, we could arrive at no very precise or certain result. We may state, however, as at least an approximation, that the globules of the diffuse vapour which occasions the appearance of coloured circles about the sun and moon, vary from the 5000th to the 50,000th part of an inch in diameter. When the halo approaches nearest to the luminous body, the largest globules are floating, and therefore the atmosphere is surcharged with humidity. Hence the justness of the vulgar remark, that a dense halo close to the moon portends rain.

Nearly the same theory has been struck out by Dr Thomas Young, to whose profound ingenuity, and most extensive information, we are glad to bear honourable testimony. By a skilful application of the principle of deflected light, he has likewise constructed the *Eriometer*, a curious instrument for measuring the size of the fibres of wool and other filamentous substances. But we cannot at present enter into the details.

Eriometer.

Meteor-
ology.

Parhelia

The same acute philosopher has given perhaps the only true account of the origin of the *parhelia* or *mock-suns*, which are frequently seen in the arctic regions during certain dispositions of the atmosphere. This gorgeous appearance of intersecting luminous arches, studded with opposite and transverse images of the sun, he ascribes to the combined reflexions of the rays from the natural facets of the snowy *spicula* floating abundantly in the air. We cannot develop this theory, however, without some discussion and the help of diagrams. It may claim our attention afterwards, if Captain Parry's return from the north shall bring us more definite information.

Phenomena
of irregular
Horizontal
Refraction
with Ex-
treme Obli-
quity.

Another most remarkable optical deception occurs in a peculiar state of the atmosphere on the verge of the horizon in various countries, and especially in the warmer climates, whether on the level plains, or on the margin of rivers or lakes, and near the sea-shore. In such situations the remote objects often appear with extraordinary elevation, and in double or inverted images. This singular phenomenon is obviously caused by the irregular refractions which the rays of light occasionally suffer by passing through the different strata of the lower atmosphere. When the effect is confined to the apparent elevation of an object, our seamen call it *looming*; but if inverted images be formed, the French and Italians give to this play of vision the appellations of *mirage* and *fata morgana*. The shipping and range of buildings on the shore of Naples have from Messina sometimes appeared floating inverted in the air. In the autumn of 1798, the coast of France was distinctly seen raised above the sea, from the beach of Hastings; the appearance lasted about an hour, and then sunk beneath the horizon. In the following year, Professor Vince watched the phenomena at Ramsgate with a large telescope. On

Observations
of Vince

the afternoon of the 1st of August he first descried the sails of a ship, but as she came fuller in view, he perceived another inverted image just below the surface of the water. Fig. 16, Plate XCVII. represents the successive appearances: A is the ship when first observed, B after she had approached, and C the inverted image. Fig. 17 exhibits a variation of the effect; A marks the ship entering the horizon, C and B the double image of the ships when near, a portion of the sea lying between their opposite traces. To produce the appearances now represented, it was requisite that the rays of light, in traversing the lower strata of the air, should describe curves, whose final tangents point in the visual directions of the objects. These curves or trajectories are delineated in fig. 15, where E marks the place of the observer, *zh* the horizon, *b* the hull, and *a* the mast of the ship; the lowest image is formed by the curves *bsE* and *atE*, above this the curves *brE* and *auE* give an inverted image, and the curves *bnE* and *amE* exhibit the highest erect image.

In ordinary cases, a ray of light, in crossing different layers of the atmosphere, describes a trajectory, which is nearly the portion of a circle, having six times the diameter of the earth. The rate of inflexion is proportional to the tangent of obliquity, and to the difference of the refractive power of the

conterminous strata, which may be assumed as the same as their difference of density. This variation in a stratum of air 28 feet thick is only the thousandth part of the whole refraction, and is hence equal to the effect of the quarter of a centesimal degree. But since a much greater difference of heat often occurs within that limit, the incurvation of the trajectory must be proportionally increased. Humidity, by dilating the air, will produce a similar effect, though in a much inferior degree, unless in very high temperatures.

Meteor-
ology.

Dr W. H. Wollaston, whose acuteness in devising philosophical experiments is unrivalled, has been able to exhibit on a small scale the various appearances occasioned by irregular atmospheric refraction. His paper inserted in the *Philosophical Transactions* for 1800, contains a very clear exposition of the phenomena. On looking lengthwise over the side of a red-hot poker at a distant object, besides the ordinary image, another inverted one was seen within the edge of the streaming air, and a larger erect one still nearer the poker, as represented in Fig. 14. The deviation was here only half a degree, but along a red-hot bar of iron, the separation of the images was increased to a degree and a quarter. On directing the eye over the surface of a green board, which had been heated by exposure to sun, a double image was distinctly seen. Another board, merely wetted with water, betrayed a similar disposition, though it was very difficult to distinguish the irregular image, its elevation being only 3'. But on moistening the surface of the board with alcohol, the images were easily seen at a separation of 15'. Still more conspicuous was the appearance on spreading a little ether over a plate of glass, for the irregular image showed itself $7\frac{1}{2}$ " raised.

Experi-
ments of
Wollaston

It was easy to imitate and examine the natural phenomena, by means of a square parallelopiped composed of plate glass. Having filled the half of this with cold water, let hot water be gently poured over it, and the cover placed upon the top. (See Fig. 15, Plate XCVII.) On standing a few feet behind the parallelopiped, and looking at distant objects through the stratum where the cold and hot water have become blended, the double and inverted images will for a short time be clearly perceived. But a more durable effect is obtained, by filling one-third of the glass case, as represented in fig. 15, with syrup, or a strong solution of white sugar, another third with distilled water, and the rest with pure alcohol. A mutual penetration slowly takes place between the conterminous surfaces of the alcohol A and the water B, and between this and the syrup C; and after the lapse of perhaps two or three days, the blending spaces become sufficiently broad for observation. The appearances then are nearly such as those that have been sketched in the plate.

This mode of experiment is at once simple and convincing. The theory which Dr Wollaston draws from it is equally ingenious, but not so demonstratively established as its author presumes. It rests chiefly on the supposition, that the stratum occupied by the penetration of two fluids of different densities, graduates in refractive intensity more slowly at its boundaries, and most rapidly in the middle. Or to

His Expt
cation.

Meteor-
ology.

borrow the elucidation of geometry, if the successive densities be denoted by ordinates, their summits will form a line of double curvature, having consequently a point of contrary flexure. This principle may be sound, though we can perceive no cogent reason why the curve of intermediate refraction should be convex or concave, or should combine both sorts of incurvation. But admitting this double curvature to be a constituent law, it will very satisfactorily explain the phenomena. The refraction will be the same, as if the light had traversed an uniform medium bounded by a surface of that reverted curvature, the convex portion diverging, and the concave portion converging the parallel rays. The different effects are exhibited in fig. 12; the distant object O is viewed in its true position by the pencil that arrives at O; it is seen inverted at I, by the rays which enter at n ; the rays which fall on r make it appear again erect at A. This explication is certainly very plausible, and may probably approximate to the truth. But though much has been already achieved, the subject of irregular refraction needs to be revised and still more closely investigated.

Several interesting objects in meteorology remain to be discussed. Regarding the *Aurora Borealis*, *Luminous Arches*, and *Aerolites*, we had a variety of new remarks and calculations to offer, but we must rather abruptly close this imperfect article. In illustration of the general principles, we only subjoin descriptions of the seasons of the Arctic and Torrid Zones, from the *Edinburgh Review*, from Hamilton's *Account of Hindostan*, and from Edwards's *West Indies*.

1. Climate of the Arctic Regions.

ed

"It begins to snow as early as August, and the whole ground is covered, to the depth of two or three feet, before the month of October. Along the shores and the bays, the fresh water, poured from rivulets, or drained from the thawing of former collections of snow, becomes quickly converted into solid ice. As the cold augments, the air deposits its moisture in the form of a fog, which freezes into a fine gossamer netting, or spicular icicles, dispersed through the atmosphere, and extremely minute, that might seem to pierce and excoriate the skin. The hoar frost settles profusely, in fantastic clusters, on every prominence. The whole surface of the sea streams like a limekiln; an appearance, called the *frost-smoke*, caused, as in other instances of the production of vapour, by the water's being still relatively warmer than the incumbent air. At length the dispersion of the mist, and consequent clearness of the atmosphere, announce, that the upper stratum of the sea itself has become cooled to the same standard: a sheet of ice spreads quickly over the smooth expanse, and often gains the thickness of an inch in a single night. The darkness of a prolonged winter now broods impenetrably over the frozen continent. The wretched settlers, covered with a load of bear-skins, remain crowded and immured in their hut, every chink of which they carefully stop against the piercing external cold; and, cowering about the stove or the lamp, they seek to doze away the tedious night. Their slender stock of provisions, though kept in the same

Meteor-
ology.

apartment, is often frozen so hard, as to require to be cut with a hatchet. The whole of the inside of their hut becomes lined with a thick crust of ice; and, if they happen for an instant to open a window, the moisture of the confined air is immediately precipitated in the form of a shower of snow. As the frost continues to penetrate deeper, the rocks are heard at a distance to split with loud explosions. The sleep of death seems now to wrap up the scene in utter and oblivious ruin.

"At length the sun reappears above the horizon; but his languid beams rather betray the wide waste, than brighten the prospect. By degrees, however, the further progress of the frost is checked. In the month of May, the famished inmates venture to leave their hut, in quest of fish on the margin of the sea. As the sun acquires elevation, his power is greatly increased. The snow gradually wastes away—the ice dissolves apace—and vast fragments of it, detached from the cliffs, and undermined beneath, precipitate themselves on the shores with the noise and crash of thunder. The ocean is now unbound, and its icy dome broken up with tremendous rupture. The enormous fields of ice, thus set afloat, are, by the violence of winds and currents, again discovered and dispersed.

"Before the end of June, the shoals of ice in the Arctic seas are commonly divided, scattered, and dissipated. But the atmosphere is then almost continually damp, and loaded with vapour. At this season of the year, a dense fog generally covers the surface of the sea, of a milder temperature, indeed, than the frost smoke, yet produced by the inversion of the same cause. The lower stratum of air, as it successively touches the colder body of water, becomes chilled, and thence disposed to deposit its moisture. Such thick fogs, with mere gleams of clear weather infesting the northern seas during the greater part of the summer, render their navigation extremely dangerous. In the course of the month of July, the superficial water is at last brought to an equilibrium of temperature with the air, and the sun now shines out with a bright and dazzling radiance. For some days before the close of the summer, such excessive heat is accumulated in the bays and sheltered spots, that the tar and pitch are sometimes melted, and run down the ship's sides."

2. Climate of Bengal.

"In the beginning of April, and sometimes earlier, particularly in the south-eastern quarter of Bengal, there are frequent storms of thunder, lightning, wind, and rain, from the north-west quarter, which happen more frequently towards the close of the day than at any other time. These squalls moderate the heat, and continue until the setting in of the periodical rains, which generally commence in the beginning of June. If the rains break up early in September, the weather is intensely hot, and the inhabitants, especially the European part, become very sickly. The natives, from the result of their own experience, assign six seasons to the year, each containing two months. The spring and dry season occupy four months, during which the heat progressively increases, until it becomes almost intolerable, even to those who are

Meteorology.

the country. In the middle districts it is lessened by occasional thunder-storms, named north-westerns; and, in the eastern, milder showers of rain are still more frequent, and refresh the atmosphere.

"The scorched inhabitants are at length relieved by the rainy season, which in general commences nearly at the same time throughout the whole province. During the first two months the rain is heavy and continual. In this period an interval of many successive days is rare, and the rain pours with such force and perseverance, that three, four, and even five inches of water have been known to fall in a single day. In the two following months the intermissions are more frequent, and of longer duration, and the weather more sultry. The rivers, and especially the Ganges, which begin to rise even before the commencement of the rainy season, continue to increase during the two first months of it, and the Ganges reaches its greatest height in the third. The average annual fall of rain in the lower parts of Bengal is seldom short of 70, and as rarely exceeds 80 inches.

"At the approach of winter the rivers begin to decrease, the showers cease to fall, and the inundation gradually drains off and evaporates. Dew, at this season, is every where abundant and penetrating; and, in the higher latitudes of India, as well as in the mountainous tracts of it, frost and extreme cold are experienced. Even in the flat country ice is obtained by the simple artifice of assisting evaporation in porous vessels, although the atmosphere be much warmer than the freezing temperature."

3. *Climate of the West Indies.*

Seasons in Jamaica.

"The vernal season, or spring, may be said to commence with the month of May, when the foliage of the trees evidently becomes more vivid, and the parched savannas begin to change their russet hue, even previous to the first periodical rains, which are now daily expected, and generally set in about the middle of the month. These, compared with the autumnal rains, may be said to be gentle showers. They come from the south, and commonly fall every day about noon, and break up with thunder-storms, creating a bright and beautiful verdure, and a rapid and luxuriant vegetation. The thermometer at this season varies considerably, commonly falling six or eight degrees immediately after the diurnal rains; its medium height may be stated at 75°.

"After these rains have continued about a fortnight, the weather becomes dry, settled, and salutary, and the tropical summer reigns in full glory. Not a cloud is to be perceived; and the sky blazes with irresistible fierceness. For some hours, commonly between seven and ten in the morning, before the setting in of the sea-breeze or trade-wind, which at this season blows from the south east with great force and regularity until late in the evening, the heat is scarcely supportable; but, no sooner is the influence felt of this refreshing wind, than all nature revives, and the climate, in the shade, becomes not only very tolerable, but pleasant. The thermometer now varies but little in the whole twenty-four hours;

its medium, near the coast, may be stated at about 80°.

Meteorology.

"The nights at this season are transcendently beautiful. The clearness and brilliancy of the heavens, the serenity of the air, and the soft tranquillity in which nature reposes, contribute to harmonize the mind, and produce the most calm and delightful sensations. The moon too in these climates displays far greater radiance than in Europe. The smallest print is legible by her light, and in the moon's absence her function is not ill supplied by the brightness of the milky-way, and by that glorious planet Venus, which appears here like a little moon, and glitters with so refulgent a beam as to cast a shade from trees, buildings, and other objects.

"This state of the weather commonly continues, with little variation, from the beginning of June until the middle of August, when the diurnal breeze begins to intermit, and the atmosphere becomes sultry, incommodious, and suffocating. In the latter end of this month, and most part of September, we look about in vain for coolness and comfort. The thermometer occasionally exceeds 90°, and instead of a steady and refreshing wind from the sea, there are usually faint breezes and calms alternately. These are preludes to the second periodical, or autumnal, seasons. Large towering clouds, fleecy and of a reddish hue, are now seen in the morning, in the quarters of the south and south-east; the tops of the mountains at the same time appear clear of clouds, and the objects upon them wear a bluish cast, and seem much nearer to the spectator than usual. When these vast accumulations of vapour have risen to a considerable height in the atmosphere, they commonly move horizontally towards the mountains, proclaiming their progress in deep and rolling thunder.

"The waters, however, with which these congregated vapours load the atmosphere, seldom fall with great and general force until the beginning of October. It is then that the heavens pour down cataracts,—and hurricanes, those dreadful visitations of the Almighty, are apprehended.

"Towards the end of November, or sometimes not till the middle of December, a considerable change in the temperature of the air is perceivable. The coasts to the northward are now beaten by a rough and heavy sea, roaring with incessant noise; the wind varies from the east to the north-east and north, sometimes driving before it, across the highest mountains, not only heavy rains but hail, till at length, the north wind having acquired sufficient force, the atmosphere is cleared; and now comes on a succession of serene and pleasant weather, the north-east and northerly winds spreading coolness and delight throughout the whole of this burning region.

"If this interval, therefore, from the beginning of December to the end of April, be called winter, it is certainly the finest winter on the globe. To valetudinarians and persons advanced in life, it is the climate of Paradise."

(D.)

MEXICO, OR NEW SPAIN.

Mexico.

As the *Encyclopædia* contains a very accurate narrative of the early history of Mexico, drawn from the best sources, we have no occasion to make any remarks on that part of this subject. We could, indeed, add but little to it, because no documents have been discovered since the period at which that abstract was drawn up, except a few hieroglyphical remains, which rather illustrate the policy, than the history of the country, under the Aztec monarchs.

New sources of information.

But the growth of Mexico since it was first subdued by Spain, its increase in population, in cultivation, and in wealth, have been laid before the public in such a luminous and authentic form by Baron Humboldt, as to merit both the attention and the gratitude of the European world. We have also been furnished with much information regarding the present state of this interesting country, of the mode in which its government is conducted, of the productions of the soil, of its facilities of improvement, and of the character and condition of its inhabitants, in the *Memorials* of the Deputies who were chosen members of the Cortes that was assembled at Cadiz. Many of them, which have been printed in Spain, give information which had escaped the notice even of the indefatigable Humboldt. The latitudes and longitudes of the most remarkable stations had not till lately been accurately ascertained, but on that subject abundant and certain documents have now been obtained. Statistical accounts of the political and territorial divisions of the population, of the revenue, the produce of the mines, the exportable surplus from agriculture, the expences of the government, the nature and number of its armed forces, and many other points, have also come to the knowledge of the European public. From these various new sources we have abstracted the view we now lay before our readers of the present condition of the most extensive community in the western world.

Extent and boundaries.

Before delineating the boundaries of Mexico, or New Spain, it is necessary to premise, that those boundaries have been the subject of serious discussion between the crown of Spain and the government of the United States of America, though now adjusted by a recent treaty.

The eastern boundary of Mexico begins in the Bay of Honduras, and including the peninsula of Yucatan within its limits, crosses to the Lake Terminos, and then due south to Tonaloa, to the eastward of the port of Tehuantepec in the South Sea. This line divides it from the kingdom of Guatemala. From Lake Terminos, northward, the Gulf of Mexico forms the boundary to the river Mexicana, in west longitude $92^{\circ} 30'$, from thence it is divided from Louisiana by a line drawn through the river Sabina, till it meets the Natchitoches or Red River, in latitude 35° north; from that point, by a line to the sources of the Rio Grande, or, as it is called more usually, Rio Bravo del Norte, supposed to be in lati-

tude 40° north. From thence its limits are an imaginary line drawn to Port San Francisco, otherwise Port Sir Francis Drake, in the Pacific Ocean, in latitude $37^{\circ} 30'$ north. The Pacific Ocean is the western boundary from Port San Francisco to Tonaloa, in the Bay of Tehuantepec, where it joins Guatemala.

Mexico

As the more extensive part of this vast country is very thinly inhabited, and almost exclusively by unreclaimed or half-reclaimed Indians (though Spain may consider it among her dominions, and in her negotiations with the American States, may successfully contend for the ownership), it can scarcely be said to belong to any other power than those rude tribes, who use it, rather as hunting grounds, than as permanent occupations. If Mexico be compared with the United States, it will be found to contain nearly the same extent of peopled country. The great mass of the population, within the States, is planted on a narrow strip of land, along the shores of the Atlantic Ocean, whilst that of Mexico is concentrated principally on the table-land on which the capital is built. The exterior country of each, the northern provinces of Mexico, and the western division of the States, are alike thinly peopled, but with this material difference, in Mexico the country most thickly peopled is the most healthy, and most fertile; whilst in the States, the country but recently begun to be settled exceeds the more ancient territory, in the salubrity of climate, and productiveness of soil.

The whole surface of Mexico is nearly 120,000 square leagues, of which about one-half in extent, and by far the most considerable in every other view, is situated in what is called the Torrid Zone, though, for reasons which will appear, the climate is much cooler than in the greater part of the other half, which is placed in the temperate zone.

The most important part of Mexico is the table-land, which occupies the centre of the viceroyalty. This tract may be considered as the continuation and expansion of the ridges of mountains which are denominated the Andes, which run through the whole extent of South America, pass through Guatemala, and send forth branches to Honduras and Yucatan. After entering Mexico, it continues its course to the northward, till it terminates on the shores of the Frozen Ocean. In Mexico, however, it expands itself to a great breadth, and without deep intersecting valleys, produces an extensive plain, equal in fertility to any part of the globe, and superior in healthiness to any other between the tropics, except singularly elevated spots. The mean height of this plain is about 7000 feet above the level of the sea. The climate at that elevation is never severely cold, the snow rarely falls, and never continues on the ground, and the severest frosts that are ever felt leave no ice which remains after the break of day. The heat of summer is so tempered by nocturnal rains, and by

Mexico.

the breezes which blow almost constantly, that the weather is never so oppressively hot as to forbid travelling or labouring in the fields at day light. Though 7000 feet is the mean height of this plain, yet it abounds with elevations, some of which enter the regions of perpetual snow, and others, whose tops are covered with snow during the greater part of the year. These masses of snow communicate a refreshing coolness to the atmosphere at all times, and in the warmest seasons the melting of them produces constant streams, which communicate verdure and fertility during their course. On the eastern side of Mexico, towards Vera Cruz, the elevation is most abrupt, and when attained the most uniform. In descending from the city of Mexico to the westward towards Acapulco, the fall is more gradual, but more interrupted by irregular elevations which intervene, than to the eastward of the city. The northern side of the plain more gradually descends, and terminates at a greater distance from the medium level, than either the eastern or the western sides. It is continued to the north-east 500 miles, and to the north-west a still greater distance. A high ridge then separates one side of the viceroyalty from the other, which is scarcely passable at any point, and divides the two parts of the country as securely as an elevated wall or a fathomless cavern.

Although the table-land of Mexico is perhaps the most healthy district on the globe, yet the other parts of the viceroyalty, on the borders of the sea, partake of the ungenial properties of the torrid zone. The eastern shore is less healthy than the western. The inhabitants of the whole coast from Tabasco to the river Mexicana are subject to fluxes and intermittent and bilious fevers, which lessen the enjoyment, and shorten the duration of human life, and though the western shores are less severely, they are not less frequently visited by the same maladies.

The eastern and western access to this important plain are both attended with difficulty and fatigue. The road from Vera Cruz to Mexico, and from thence to Acapulco, are both impassable for wheel carriages; and passengers who cannot travel on foot, or endure the fatigue of horses or mules, are conveyed in litters, a kind of sedan chair, the long poles of which are fastened to the sides of two mules, one of which precedes, and the other follows the carriage. A road, however, of the most magnificent kind is now constructing from Vera Cruz to the capital; great progress has been made in it, and but for the interruption caused by the tumults which began in 1810, it would have been completed by this time: it is carrying on in some parts by the sides, in others over the tops of the mountains, and in one part it crosses a mountain 10,400 feet above the level of the sea, and 3000 feet higher than the spot on which the city of Mexico stands. Whenever this communication shall be completed, it will give a wonderful stimulus to the agriculture of Mexico, which, for want of roads to convey its surplus produce, cultivates only as much land as is required by the domestic consumption; and hence, when a year of less than usual fecundity occurs, it is exposed to great scarcity, if not to absolute famine. To the northern part of the vice-

royalty, where it is of less consequence, the communication is so much better, that a coach may travel all the way from the capital to the city of Santa Fé, a distance of 440 leagues, with no interruption, and with very little risk. As the road to Acapulco is not passable for wheel carriages, those commodities which Asia furnishes to the commerce of Mexico are conveyed on the backs of mules. Rivers of great extent, and subject to frequent inundations, present obstacles which are difficult to conquer. Large sums have been destined to construct bridges over two of these rivers, the Papagallo and the Mescala, but without effect, and passengers must be conveyed across them on temporary rafts, made of reeds, which are rendered buoyant by having gourds beneath them. These rafts are guided by Indians accustomed to the business, who swim with one hand, and direct the course of the floating raft with the other.

A road has been begun from Vera Cruz to Perote, the place at which the silver and other valuable commodities are collected and deposited, till they can be conveyed to the coast. Already L.600,000 Sterling has been expended on it. The cost *per* mile is about L.7000, in a country where the labour of Indians, who are principally employed on it, does not cost one-half as much as the wages of labourers in Europe. This road is broad, solid, and of easy ascent, and equals the celebrated roads of the Simplon and Mount Cenis. Pillars of porphyry are intended to be placed along it, which will both indicate the distance and the elevation of the spot above the level of the sea.

The question of the population of this viceroyalty becomes the more interesting, from the great errors which prevailed on the subject, before the publication of Humboldt's *Political Essay on the Kingdom of New Spain*. In the *Encyclopædia* the inhabitants are estimated at 2,000,000. Pinkerton, after discussing various reports and opinions, sums up by estimating all the inhabitants of Spanish North America, including Guatemala (now known to contain more than 1,200,000), at about 3,000,000. By an actual enumeration made in 1793, in which the returns of two intendancies were made to depend on calculation, it appears that the number of inhabitants were 4,482,529; but for reasons which appear satisfactory, Humboldt contends that they amounted to 5,200,000. The Baron had peculiar advantages in forming an estimate of the population in 1803, when he was in Mexico. From the information of the clergy, whose registers of births and deaths are accurately kept; from the increase in the production of the soil, as evinced by the tithes, which are strictly exacted; and from the proportion of births to deaths, he has framed his estimate, which, if it does not arrive at accuracy, must approximate to it as nearly as the nature of the case will admit; and if it in any degree errs, it must be in under rather than in over-rating the number of inhabitants. He found the births to be to the deaths in the proportion of 170 to 100; the births to the number of inhabitants to be 1 to each 17; and the number of deaths to be 1 in 30; whilst, in France, which may be considered as the fair average of Europe, the births are to the deaths as 110 to

Mexico.

Mexico. 100; the births 1 to 28th of all the inhabitants, and the deaths 1 to 30th.

The result of his calculations give 6,500,000 as the population in 1803, being an increase of 25 in the 100 in ten years. If the same increase has continued, which there is no reason to doubt, in the year 1813 the population must have advanced to 8,150,000; from that period to the present, 1821, calculating at the increase of 15 *per cent.* for the eight years, the numbers now would exceed 10,000,000. During part of this period, great internal commotions prevailed, which must have checked the growth of the population, and therefore some allowance must be made for that circumstance. It is very difficult to calculate the effect of such wars as Mexico has entertained; because the mere loss of life forms a less important feature in the estimate, than the effect which is produced by the neglect of cultivation, and the consequent scarcity of subsistence, which tends both to destroy and to prevent life. In stating the present population of the viceroyalty at 10,000,000, we cannot be in any great error, as the introduction of the practice of vaccination must have had a tendency to correct a malady which previously produced dreadful ravages. In the year 1779, upwards of 9000 persons died of the small-pox in the capital alone, and its effects in other parts of the country were still more fatal. It is but justice to a most public-spirited individual to state, that, by the activity of Thomas Murphy, of an Irish family in Malaga, but who had taken up his residence in Vera Cruz, the virus was brought from the United States to that city, in 1801. The cow-pox appeared in its mildest form; it was communicated to all classes with facility, and even the Indians readily submitted to the operation, though they are usually too stupid to be very careful in adopting remedies to prevent evils not immediately before them. It has now spread through the whole extent of North and South America; and it is asserted that several of the most savage of the tribes have adopted it.

as of
bitants The classes into which the inhabitants of New Spain are divided is an object of great importance, when sketching a view of the country; and upon this subject the diligence of Humboldt has furnished us with ample details, which are here presented to the readers in an abridged form.

The first class is that of the Europeans, who have taken up their residence in Mexico. They are commonly there called Gachupines by the other inhabitants. They generally fill the most lucrative and honourable offices in the state, the courts of law, the boards of revenue, the church, and the army; and the greater part of the more opulent merchants are of the same class. They generally assume, even when in no official situation, nor possessed of any considerable property, a degree of importance which is by no means acceptable to those white men who are natives of the country. The Indians, however, look up to this class with great respect, and almost affection, as they see, or suppose they see, in them, protectors from the oppression which the white natives exercise towards them. The whole number of European Spaniards is not estimated at more than 100,000, the far greater part of whom are established in the capi-

tal, and the other large towns. They do not constitute more than 1-70th part of the whole population; and, in 1813, were calculated to be, to the white Americans, only as 1 to 14. They consist principally of males of mature age, the females not being more than 1 in 10 of the whole number. This greater proportion of males in the meridian of life, the stations they occupy, and the superior activity of mind which they have acquired by a European education, gives them an importance in the community very far beyond what their relative numbers alone would confer.

The next class to the Europeans is that of the un-Creoles. mixed whites, natives of the country, the descendants of the first adventurers who subdued it, or of others who from time to time, have emigrated from the European peninsula. As the Spaniards, from having so small a proportion of females, intermarry with the natives, and their offspring thus become Creoles, the disproportion between these two classes of whites is becoming greater daily. In the year 1803, they were calculated, when compared to all the other inhabitants, to be one-fifth of the whole number. They certainly multiply more rapidly than any other class, both from the greater ease of their situations, and because the mixed class, to whom we shall presently attend, are constantly falling into their ranks, and increasing their numbers. After five or six crosses between the whites and the coloured classes, the children become so nearly white, that they are easily reckoned as such; and, where doubts are entertained, the courts, upon proof being exhibited to satisfy them, decree that they are to be considered white men. It is a remarkable fact, the truth of which, however, cannot be doubted, after the pains taken by Humboldt to verify it, that the proportion of females to males is much greater among the Creoles than in any of the other gradations of Mexican population. This is clear in the villages, but not so striking as in the cities, where the proportion is 134 females to 100 males. The Creoles are possessed of almost the whole of the property in Mexico; the richest mines, the most fertile tracts of land, and the most productive plantations, are in their hands; and some of them derive revenues from their estates far exceeding those of the most opulent European nobility. The family of Valenciana, now ennobled, exclusive of the rich mine from which the title is derived, enjoyed rents amounting to more than L.90,000 *per annum*, whilst the produce of the mine, *communibus annis*, yielded a nett revenue of L.65,000. Count Regla, proprietor of the rich mine of Biscaina, built, at his own expence, two ships of the line, one of 120 guns, and presented them to the king, and lent him L.200,000, which has never been repaid, from the profits of a new seam of silver he had discovered. But the family of the Marquis of Fagoaga derived the greatest revenue, from the mine of Sombrete, that the history of mining has recorded. The nett produce, in six months, was upwards of L.800,000. Besides these and similar incomes, derived from mining, several of the Creole nobility possess estates on which no mines are worked, that are nevertheless vastly productive. The Duke of Monteleon, the lineal descendant of Cortes,

Mexico. enjoys an estate, in the province of Oaxaca, worth more than L.60,000 annually, though it has recently been deprived of some branches of revenue, which have diminished it one-half. Though some enormous fortunes, acquired by mining, are transmitted to the descendants of the proprietors, yet there is greater fluctuation in this than in any other species of property. Money, rapidly gained, is generally as rapidly dispersed; and as the thirst for wealth is never satiated, those who are most successful by one mine, dissipate their riches in exploring others, whose first expence is certain and enormous, whilst the returns are frequently uncertain or trifling. It has not unfrequently happened, that the sinking of a pit, and the attendant works, has cost near L.5,000,000 Sterling, and the work been abandoned without any silver ore being discovered, or any of sufficient richness to pay the expence of separating it from the other substances that it is incorporated with. That class of Creoles who have confined themselves wholly to agricultural operations have generally secured to their families estates of increasing value, and have transmitted that uniform prosperity which neither mining nor commerce are so well fitted to secure. Though the wealth of the country is mostly in the hands of the Creoles, they are far from being all individually rich; perhaps in no class of society, in no country in the world, do the two extremes of excessive riches and excessive poverty so often meet. The pride of the Creoles, an aristocratic feeling, founded on their complexion, which gives them distinction, prevents them from pursuing those kinds of labour that are deemed degrading to gentlemen. The consequence is, that their poverty is often even greater than that of the Indians, whilst indolence, added to pride, prevents them from following any employment beyond that of the gaming table, or becoming the flatterers of the richer members of their own class. In the tremendous collisions which have recently been experienced in Mexico, the Creoles of this description have been the most energetic leaders, and have drawn into their projects many of the more rich and more successful of the white natives. Whatever of science or learning is cultivated in Mexico is almost exclusively for the benefit and improvement of this class. The University of Mexico, the Schools of Mineralogy and Chemistry, are almost solely filled by pupils from this class of society; and, as those establishments are extensive, the benefit communicated by them is gradually extending to a larger portion of the community. The greater part of the parochial, and some of the dignified clergy, are prepared for their functions from among the Creoles: some few have filled the episcopal chairs, and some who have followed the profession of law have attained to the dignity of members of the royal audience.

Unmixed
Indians.

The Indians form the next class of the Mexican population; they are the unmixed descendants of the aboriginal inhabitants. They have generally remained on the same spots which their ancestors occupied, and have followed the occupations they pursued, with very little other change than substituting the Catholic rites in the room of the sanguinary religion that was formerly practised under their native

emperors. The districts that were most populous at the time of the conquest have, at this day, the greatest proportion of Indian population, whilst in those provinces which were then occupied by savages, in a ruder state, who were mere hunters or fishers, such as New Biscay and Durango, there are scarcely any Indians now to be found. The Indians of Mexico are of a darker colour than those of South America, though they live in a climate of lower temperature. They have more beard, and more hair on other parts of the body, than those of the southern continent. They are almost all of them free from personal deformity. The hunch back, the squinting eye, and lameness in the hands or feet, are unknown among them. Among savage tribes, this exemption from personal deformity has been attributed to their erratic vocation, in which the weak would necessarily perish in their youth; but the Indians in Mexico have been stationary for three centuries; they have pursued the common agricultural labours, and in their habits resemble the cultivators of other countries. It is then, perhaps, natural to conclude, that this more perfect form of the human figure is derived from some modification in the constitution that is peculiar to the swarthy race, since it extends also to the Africans and the Asiatics. Whatever the appearance of the moral faculties of the Indians may be at present, it is impossible to estimate them with impartiality, unless we consider some of the circumstances which accompanied their subjection. At the time of the invasion by Cortes, the whole country was divided into two classes, the aristocracy and their slaves, for such was the condition of the more numerous body. Without contending that the progress of cultivation was very great among the Indians, yet from many facts which have come to our knowledge, we may assume that civilization and knowledge, as far as they had extended, were confined to the higher classes, who preserved and transmitted their acquisitions, in arithmetic, in astronomy, in architecture, and religion, by the hieroglyphical paintings, which were understood only by them. The higher classes perished almost wholly in the contest which ended in the subjugation of their country. The priests, who were the depositories of science, who resided in colleges around the temples, and who made the astronomical observations which regulated their calendar, were exterminated by the fanaticism of their Catholic conquerors. The Spanish monks burned the hieroglyphic paintings by which knowledge had previously been transmitted from one generation to another. The people were thus plunged in ignorance, and which became so much deeper, from the missionaries being unacquainted with their language, and being therefore unable to substitute new ideas in the room of those the propagation of which they had stopped. The Indian females of the more elevated ranks were disposed to share what property they had secured, by forming alliances with the Spaniards, rather than to commit themselves with their countrymen, thus reduced to poverty and contempt. The rest of the natives consisted only of the indigent race, who, under their aristocratic countrymen, had been kept in subjection, and were in total ignorance of what little knowledge existed in

Mexico. the country. They were either the cultivators, the lowest class of artisans, the porters who had been accustomed to be treated as beasts of burden, or those numerous beggars, who, when Cortes first visited the country, crowded the streets of all the great cities. The few of the chiefs that were left concealed their rank from the conquerors, and with no other decorations than the lowest of their tribe, were satisfied in receiving from them that voluntary homage which custom had long sanctioned.

It is impossible to judge what faculties may be developed in a nation by seeing only the remains of its lowest class, and those in a state of subjection and oppression. Humboldt has said of the Indians of Mexico, "I know no race of men who appear more destitute of imagination. When an Indian attains a certain degree of civilization, he displays a great faculty of apprehension, a judicious mind, a natural logic, and a partial disposition to subtilize or seize the finest differences in the comparison of objects. He reasons coolly and orderly, but never manifests that versatility of imagination, that glow of sentiment, and that creative and animating art, which characterize the nations of the south of Europe, and several tribes of African negroes." The Indians generally reside in their own towns and villages, where they are governed by their chiefs, who, if the laws enacted by Spain were all obeyed in her colonies, would have the rank and privileges of Castilian nobility. It is now difficult to distinguish the chief from the others of his tribe, as they affect, in their dress and mode of living, to exhibit an appearance of poverty, under which they may, with less observation from the intendants, practise oppression on those they govern. They are the collectors of the capitation tax which is paid by the Indians, which they levy most rigidly, and at the same time extort considerable sums for their own emolument. These caciques now display the same vulgarity of manners, and the same want of civilization, as the lower Indians, and appear to excel them in nothing but that chicanery by which they extort from them a portion of their gains. The caciques being recognized as nobles, might pursue the law, or enter the army, and arrive at distinction; but few have chosen these professions; many of them, however, become priests, and the females of this cast are almost the sole occupiers of the convents.

The Indians are acknowledged by the laws to be freemen; and though, when in their own towns, they are governed by their native chiefs, and are treated as in a state of pupillage, they may leave those towns, take up their abodes where there is no cacique, and dispose of their labour to the best advantage. In this manner some families have established themselves in places not under the native governors, and have acquired considerable wealth. The great check to improvement with this race is their fondness for ardent spirits, particularly one kind, called *Pulque*, which is distilled from the Agave, with which they intoxicate themselves habitually, if they can procure it. As the price of this spirit is very low, whenever they work free from their chiefs, they can procure sufficient by labouring a small portion of their time, to indulge

in drunkenness during the remainder. The tribute paid by the Indians is a poll-tax on all the males between the ages of ten and fifty. It has been frequently diminished in the last two hundred years, and now varies in different provinces of New Spain, amounting in some to one dollar annually, in others to nearly two. The Indians are, however, exempt from all other imposts, even the *Alcavala*, which every other subject of Spain pays on the sale of all productions. The capitation tax was intended to favour, not oppress the Indians, but by the knavery of their chiefs, probably in collusion with the white inhabitants, it is made an engine of considerable extortion. The Indians, however, pay ecclesiastical dues, which, in their narrow circumstances, press hard on them, but from their superstitious attachment to the showy ceremonies of the church, are borne with more cheerfulness than the tribute. The court of Spain, in order to benefit the Indians, have recently appointed an order of magistrates (*Subdelegados*), whose office it is to protect them. These were mostly chosen from the white natives, and the institution, instead of benefiting, appears to have depressed still more the unfortunate race, who endeavour, but generally in vain, to obtain redress from the extortions of the *Subdelegados*, by appeals to their priests, who, being often of their own race, have not sufficient power to protect them against the white Creoles. The Indians consider the Creoles as their oppressors, and the Europeans as their protectors; and hence the animosity between the two classes of white inhabitants becomes inflamed, whilst the poor Indians, from the scarcity of Europeans near their villages, and from not understanding their language, can scarcely even obtain that relief which, if their complaints were made known with facility, would sometimes be administered to them. Though the Indians have appeared patient under suffering, and excessively indolent, yet when their vengeful passions have been roused, they have discovered most vehement feelings, and have shown themselves capable of strenuous exertions. The same Indian who has patiently suffered himself to be whipped at the door of the church, for some ecclesiastical offence, and has meekly thanked the reverend executioner for the correction he has administered, has appeared cunning, active, impetuous, and cruel, when acting with his brethren in the late popular disturbances. The number of unmixed Indians in the whole of New Spain may be estimated at near 3,000,000, and, by every document, it is clearly proved, that they have of late rapidly increased, though not with a rapidity equal to that which the Creoles and mixed casts have exhibited.

The class of mixtures from the primitive races has, in process of time, become a very important portion of the population of New Spain. In a country where rank depends more on the complexion than on the endowments, which, in other countries, confer distinction, it is not surprising, that almost every shade has its limits defined by terms, which, though apparently only expressing the colour, do in reality express the rank of the individual. As the terms used frequently occur in all books relating to the Spanish colonies, an explanation

Mexico.

Mexico. tion of them may not be useless. The son of a white, whether Creole or European, by an Indian female, is called *Mestizo*. His colour is almost a pure white, and his skin is of a peculiar transparency. The small hands and feet, and a certain obliquity of the eyes, are more frequent indications of the mixture of Indian blood than the nature of the hair. If a *Mestisa* marry a white man, the second generation scarcely differs in any thing from the European race. They are generally accounted of a more mild character than the mulattoes descended from whites and negresses, who are distinguished by the violence of their passions, and the singular volubility of their tongues. The issue of negros by Indian females bear in Mexico the singular name of *Chinos*, or *Chinese*, in common language; though by the laws they are denominated *Zambos*. The term *Zambo*, however, is generally applied to the descendants of a negro and female mulatto, or a negro and a female Chinese. Another gradation, called *Zambo prieto*, or blackish *Zambo*, is the offspring of a negro and female *Zamba*. From the union of a white man and a mulatto woman the class of *Quarterons* is derived. When a female *Quarteron* marries a white man, the children are denominated *Quinteron*. The issue of a white man by a female *Quinteron* is considered as white, and is elevated to the highest rank. The number of these mixed casts is generally estimated to be equal to that of the pure Indian race. They are none of them in a state of slavery, but form the class from whence the lower kinds of traders, manufacturers, servants, sailors, and labourers, are furnished. They constitute the middle and lower ranks of society, in general, though some of them rise to wealth and knowledge, and thus, by connecting themselves with those a cast whiter, prepare their offspring for the highest municipal stations. The number of negros, whether slaves or freemen, is very inconsiderable in Mexico; of the 74,000 negros which are annually drawn from Africa for the Spanish colonies, not more than 100 are landed on the shores of Mexico, and these are generally employed in the hot countries on the coast, which are equally destructive of the lives of the Indians from the interior, and the newly imported natives of Europe. But though there are few or no negro slaves in Mexico, a species of slave kidnapping is carried on, if possible more disgraceful than that on the coast of Africa. The missionary monks make incursions into the territories of those unclaimed Indians, whom they call *Indios bravos*, because they have not, like those of the missions, *Indios reducidos*, learned to make the sign of the cross. Impelled by a mixture of fanaticism and cupidity, they surprise all they can, even old men, women, and children. The prisoners taken in this petty warfare, which is constantly carried on in the *provincias internas* on the frontiers of New Spain, are not indeed numerous. The tribe that is most commonly subject to these incursions is called *Mecos*. When seized, they are generally conveyed as prisoners to the house of correction in the capital, where their ferocity is often increased by solitude and despair. When conducted to Vera Cruz, Havana, or other warm climates, they speedily perish,

Mexico. as all the savages of the mountains do when compelled to labour in the most sultry of the tropical regions. These *Mecos* sometimes escape from their confinement, or their masters, and commit the most barbarous cruelties before they can be subdued. The whole system is most disgraceful, and the more from religion being made the pretext for continuing it.

Notwithstanding the considerable population of Commerce. Mexico, and its extensive agriculture, its external commerce is but insignificant. This may arise in a great degree from the impolitic and unjust restrictions laid on it by the European metropolis, but in a greater degree from the varieties of the soil and climate, being such as to produce all that man can want; and from the population being so thinly planted as to render the value of the surplus production scarcely equal to the expence of conveyance from the place of its growth to any other place of consumption. On the eastern side of Mexico the whole external commerce is restricted to the ports of Vera Cruz, Campeche, Huasacualco, Tampico, and Santander; and if the restrictions did not legally exist, it would be almost impossible for any other port to trade to a considerable extent, from the shallowness of their water, and the obstructions of their bars. As the trade of Vera Cruz is, however, of exclusive importance, the consideration of that must be principally attended to. The harbour, if it deserves the name, is protected from all but northerly winds, by a cluster of islands which surround it, and is rather a strait between the main land and the island Gallega, on which the castle of St Juan de Uloa stands, than a secure port. The depth of water at the entrance is four fathoms, and at the moorings not more than four and a half. The ships are secured by having their cables fastened to ring-bolts fixed in the castle of St Juan. The tide rises but once in twenty-four hours, and varies from one to three feet in its rise. When a violent gale from the north occurs, the vessels are no longer safe, but must seek security by running to sea, and if the gale does not endure so long as to drive them on the shore of Campeche, when it is over they may return to their moorings. The nature of this port is an impediment to commerce, but none better has been found by which a connection with the interior can be maintained. The city of Vera Cruz is peculiarly unhealthy, and equally dreaded by the sailors from Europe and the natives of Mexico, who descend from the table-land to convey the goods to and from the shore. The merchants, too, among whom are some of very great capital, prefer residing at Xalapa, to breathing the pestiferous air of the hot region, and thus the climate, as well as the physical imperfections of the port, acts as an impediment to commerce. Considered as a single port, and viewing the circumstances of its position, the trade of Vera Cruz is enormous, but as the only point of commerce for a rich country of eight or ten millions of inhabitants, it is very small.

The importations consist principally of the superior kind of clothing which are required by the higher classes, of wine and brandy, of paper and iron. These amount together to about L.4,500,000 Sterling. Besides, there are imported from the other Spa-

Mexico. nish settlements in America various articles, but principally cocoa and bees-wax, to the amount of about L.350,000, thus making the whole imports somewhat less than L.5,000,000. The exports consist almost wholly of the precious metals, of cochineal, and indigo. Some sugar is exported, and it is an increasing production, which, when the new road is completed, must be very considerably augmented. Flour has also of late been exported to the islands, especially to Cuba, and this commerce must also increase as the roads are improved.

Average Value of Exportations from Vera Cruz computed in British Sterling.

To Spain.	
Cochineal, - - -	L.760,000
Indigo, - - -	725,000
Sugar, - - -	325,000
Gold and silver, coined and wrought, - - -	3,950,000
Various small articles, amounting together to - - -	56,000
	<hr/> L.5,816,000

To the other Settlements in America.

Flour and other provisions, - - -	L.137,000
Gold and silver, - - -	813,000
Various small articles, amounting together to - - -	50,000
	<hr/> -L.1,030,000
	L.6,846,000

The commerce is carried on by about two hundred and fifty vessels of different sizes, which annually load and unload here. The greater part of the indigo, and some part of the cochineal, are the products of Guatemala, brought to Vera Cruz for the convenience of transporting to Europe. These are conveyed partly by land and partly by the river Huasacualco, and merely pass through Vera Cruz; and in estimating, the exports ought to be deducted from the amount: allowing for these one million, the whole exported productions of this vast country, independent of gold and silver, does not exceed in value in the whole year what is exported from Great Britain weekly.

Humboldt states the number of persons employed in the mines not to exceed 30,000, or one in two hundred of the whole population; the exportable produce of whose labour amounts to L.4,793,000: whilst the surplus produce of all the rest of the inhabitants does not amount to much more than one-fifth of that sum. The United States of America, with a population nearly the same as Mexico, having about as many negro slaves as New Spain has of Indians, and cultivating a less grateful soil, have been enabled to export surplus native productions to fourteen times the amount, and Great Britain, with only half as many more inhabitants, exports sixty times as much.

The commerce of Vera Cruz is under the direction of a body called the *Consulado*, consisting of the most eminent merchants. This body acts as a court

of justice in all commercial affairs, which they decide with promptitude and equity, without the intervention of lawyers. As a corporation they enjoy considerable wealth, which is expended in promoting the security of the port, and in improving the roads that lead to it. For these purposes a tax is levied on all imports and exports, which is expended under their direction. The other foreign trade of Mexico, if that can be called a foreign trade which is carried on with a colony of the same sovereign, is from Acapulco in the Pacific Ocean, to Manilla. Acapulco is one of the best harbours in the world; it has two entrances, and is completely sheltered by the island at its mouth, which separates these entrances. The anchorage is good in from ten to twenty-five fathom water. Though the immediate vicinity of this port is a barren soil, and the situation at present unhealthy, yet in process of time it must become a place of considerable importance. There are few inhabitants except at the fair, which is held on the arrival of the ship from India, when both the town and the neighbouring villages are crowded with visitants. This whole trade is carried on by a single ship called the galleon. It is usually from 1200 to 1500 tons burden, and is commanded by an officer of the royal navy. It sails from Manilla the latter end of July or beginning of August, loaded with calicoes, muslins, silks, spices, drugs, and the other valuable productions of India and China. The value of this cargo is limited by law to five hundred thousand dollars, but it generally amounts to treble that sum. The merchants of Mexico and Lima are interested in the expedition; but many of the ecclesiastical corporations invest part of their funds in the speculation. The arrival of the galleon draws to Acapulco numerous purchasers, who are frequently disappointed, by finding, on their arrival, that, by a combination among some of the great capitalists of Mexico, the whole cargo has been disposed of in a single lot. The returns from Acapulco to Manilla are made almost wholly in coined silver, and amount to between one million and a million and a half of dollars. Some iron is sent, a little cochineal, oil, cocoa, and wine, but these are of small amount. Many passengers go by this annual ship to Manilla, especially the missionary monks who are destined to make proselytes on the Philippine Islands. A small portion of commerce is conducted between Acapulco and the ports of Guayaquil and Lima. The vessels from the south bring Peruvian wine, oil, copper, and cocoa, and return with a few woollen goods manufactured at Queretaro, some cochineal, and a quantity of contraband East India articles. Though this passage from south to north is easily accomplished, yet in the imperfect state of the art of navigation which is practised on the coasts of the Pacific Ocean, it generally requires more weeks to return than it does days to arrive. Acapulco, in the hands of a power with capital and industry, might command the whole of these two valuable branches of the fishery from which the English and the Anglo-Americans have derived such great advantages. The sperm-ceti whales are caught on the very coasts, and the black whales are abundant a few degrees to the northward; but though the Mexicans have constantly

Mexico.

Mexico. before their eyes the benefits which their rivals draw from this source, not a single vessel has ever been equipped by them for either of these fisheries. The trade in furs on the north-west coast of America, and the conveyance of them to China, belongs to this part of the world, from whence traders would find advantages that would defy any competition from those who are obliged to coast the whole of North and South America on both sides the continent, before they can reach the station where their trade commences.

**Agriculture,
and its Pro-
ducts.**

The view taken of the face of the country in New Spain must have shown that it is capable of producing all the fruits which can be found in the various climates and countries of the globe. In the account of its agriculture we must, however, enumerate and describe not what it is capable of producing, but what it actually does produce. Indian corn or maize is the most important to the natives of any aliment which is known. It is cultivated in Mexico from the warmest regions up to the height of 9000 feet above the level of the ocean. Its fecundity, in favourable years, in fertile soils, and in proper situations, is wonderful. Its increase in these circumstances has been ascertained to be from three to four hundred times the quantity of the seed that was sown. The general average of the increase is stated to be from 130 to 150 for one. When it returns no more than seventy for one, the cultivation is thought to be not worth continuing. It is used for food in a variety of ways; the green ear is boiled or roasted, and eaten in that state, when it is not unlike green pease. When ripe it is bruised to a flour for bread, or for thickening the soups of the inferior casts. It is used on the declivity of the mountains, above the height in which the sugar-cane will flourish, to make an ardent spirit, in the use of which the Indians indulge to great excess. By expressing the juice from the stalk a sugar is formed, but the sugar-cane having of late been much extended in its growth, has in a great measure superseded this application of the maize. Though maize is sometimes a most abundant crop, yet there are seasons when, in some districts, it almost wholly fails, and the inhabitants feel the severest want. The price of this grain regulates that of almost every other commodity in Mexico. When either a premature frost, or the absence of rain, destroys the harvest, both human beings and the domesticated animals suffer the severest misery. It is, however, a slight alleviation of their sufferings, that the scarcity seldom visits both the warmer and the colder regions in the same year; but the badness of the roads, and the great distance from one district to another, prevents the surplus of one part from relieving the distress of another to any effectual extent. Wheat is one of the presents which the old continent has conferred on the new. The first introduction of it into Mexico was in the year 1530, when a negro slave of Cortez found three or four grains of it among some of the rice. These were sown, and the produce distributed to be again sown, till it has become general. The highest and the lowest regions in Mexico are equally unfit for the cultivation of wheat. It is only grown in the southern provinces, at the elevation of 2650 to 4250 feet above the level of the

Mexico. ocean. In the more northern provinces it is produced at a lower elevation. The increase of wheat, in most parts of Europe, is calculated to be about five for one on the average of different countries; but in Mexico, at the proper elevation, it generally yields from thirty to forty for one, and at Cholula, it has exceeded seventy or eighty for one. The great impediment to the cultivation of wheat and other grains of the *cerealia* species, is the want of moisture. Long continued droughts frequently destroy the hopes of the cultivator. In no part of the world does artificial irrigation so abundantly repay the expence that is incurred; but, owing to want of skill in conducting the rivulets which the melting of the snows form, and perhaps more to the want of capital, this important operation is either omitted or negligently executed. On some farms, where the system of irrigation is followed, they water the wheat twice; first, when it shoots up in January, and again in March, when the ear begins to be formed. By leaving the land flooded for some weeks at this latter period, the tenacious soil imbibes such a quantity of moisture, as enables it to resist the deleterious effects of the long droughts, and the burning sun which it subsequently endures. In these irrigated farms, as in Egypt, the seed is sown when the flooding commences, and this is thought to destroy many of those weeds which would be injurious to the crop. The tillering of the wheat plants in Mexico, as well as the number of grains in each ear, is most astonishing. In the best lands, and in the most favourable seasons, we have seldom seen more than six or seven shoots from each root that produced ears, and those ears average from sixty to seventy grains in each. In Zelaya, a cultivator took, at random, from a field of wheat forty plants, and Humboldt found from forty to seventy stalks from each plant. The grains were counted, and were found in different ears to be from 120 to 160. The soil of the wheat lands is generally composed of tenacious clay, mixed with basaltes and amygdaloids, which, though difficult to pulverise, such land, when brought into proper culture, is best adapted for the growth of that plant. Rye and barley, as they resist a greater degree of cold than wheat, are grown on higher elevations. The produce is not much greater than on the lands of some of the best cultivators in England. Oats are scarcely cultivated in Mexico, where, as in Spain, the horses are fed on barley, though sometimes maize is used for that purpose.

Potatoes, for which Europe is indebted to America, are much cultivated in Mexico. It is not an indigenous plant, but was transported from the mountainous parts of Peru, at a very early period after the conquest of that country. It has been generally asserted, that the potatoe is a spontaneous production of the Andes, but Humboldt and his companion, Bonpland, though diligently herborizing from the fifth degree of north to the twelfth of south latitude, found none in a wild state with nutritive roots. They, however, were led to suppose, that in the Andes of Chili they are indigenous. In Mexico, they are cultivated on the highest inhabited lands. The natives preserve them for several years, by exposing them first to the frost and then to the heat of

Mexico. the sun. They grow to a large size; some of them were found by Humboldt to measure from twelve to thirteen inches in diameter, and to be better tasted than any that are grown on our continent.

The banana is, to the inhabitants of warm regions, what grain is to the people of temperate and cold countries; but infinitely more beneficial, in as much as on the same portion of land, and with the same quantity of labour, a much greater quantity of nutritive sustenance may be produced. Within eight months after planting, the banana begins to form clusters, and these may be gathered in the tenth or eleventh month of their growth. When the stalk is cut, some other shoots from it, about two-thirds the height of the parent plant, are left standing, and they bear fruit in about three months after. Thus a plantation is perpetuated, without any other subsequent labour than that of cutting the stalks on which the fruit has ripened, and occasionally digging and dressing round the roots. The ripe fruit of the banana resembles, in appearance, the bean pod, but is far larger. When exposed to the sun, it is dried in the same manner as the figs of the south of Europe. The skin then becomes black, and emits a smell resembling that of a smoked ham, and in that state becomes an object of considerable internal traffic. Its taste is agreeable, and it is considered to be very wholesome, whilst the ripe fruit, in its crude state, is found difficult of digestion by newly arrived Europeans. The green fruit is frequently cut into slices and dried in the sun, and being thus rendered friable, is reduced to powder, and serves the purposes of flour in many culinary preparations. The facility with which this food is produced, gives it an advantage over every other alimentary substance in the same climate. Even the bread fruit, though it affords food through almost the whole year, may be destroyed by an enemy, and cannot be quickly reproduced, whilst the banana, if destroyed, may become available again for subsistence in a few months by planting suckers. The produce of the banana, as compared to that of wheat, is estimated as 133 to 1, and to potatoes as 44 to 1. The facility with which food can thus be obtained in the hot regions, necessarily creates great indolence in the inhabitants. With two days slight labour in each week, a man may gain sufficient subsistence to support a family; and yet such is the love of their native spots with the inhabitants of the mountains, that though a single frost may destroy the labour of the year, none of them will emigrate to the thinly inhabited plains, where nature showers her gifts with such profusion.

In the same temperature which favours the cultivation of the banana, the manioc, or cassava, is grown, and, like it, is abundantly productive of aliment. There are two kinds of manioc; one, called the sweet, may be eaten without injury, the other, the bitter, is a very active poison in its crude state; both are made into bread, but the latter is most generally used for that purpose. The root is first dried, it is then grated, and the juice carefully expressed, by which means a tolerably palatable and wholesome flour is produced. It is generally made into thin cakes, not unlike the oat-cakes eaten by the labourers in the west of Yorkshire. It has the

great property of keeping a very long time, and is not liable to be attacked by worms, or the other insects which, in warm climates, are so destructive of other bread. The cultivation of the manioc requires more care than the banana, and in some measure resembles that of potatoes; the slips are planted, and in seven or eight months the harvest may be gathered.

Almost every species of fruit is produced in Mexico, and the esculent vegetables of every climate are profusely scattered; some of these are indigenous, but some of the best, as the various cabbages, the turnip, the carrot, and pease, have been introduced by the European settlers, and have multiplied till they have become as abundant as the native productions. The jealousy of Spain has prevented vines and olives from being extensively cultivated; but when they are attended to, they yield abundance of fruit. The court of Spain, instigated by the commercial jealousy of its merchants and agriculturists, has always discouraged the cultivation of the vine, the olive, the mulberry, and of hemp and flax. They are generally prohibited in the colonies; but it is difficult to execute the law with rigid strictness. Whilst Humboldt was in Mexico, an order was received from Madrid, to root out all the vines in the northern part of the viceroyalty, because the merchants of Cadiz complained that the vent for their wines and brandies had diminished; but the viceroy would not obey the order, judging that, notwithstanding the great patience of the inhabitants, they would not submit to have their property laid waste, merely to gratify the cupidity of the European monopolists.

After sketching those productions which constitute the food of man, we may notice those which furnish his beverages. The most important of these is called the Maguay, a species of cactus, or opuntia. The plants are set about five feet asunder in rows. When the head of the plant throws forth the bundle of central leaves, they are cut off, and a hole is scooped in the stalk, which is covered with the leaves. In this hollow the plant seems to deposit all the juice, which, without the excision, would go to form the flowers. It is a real vegetable spring, running for two or three months, and which may be emptied twice or thrice in the day. The plants are very productive; a single one will yield 150 quarts of honey (for so in this state it is called) annually. It is placed in a situation to ferment, an operation which takes place in a few days, when it becomes fit to drink, and is called *Pulque*. It is said in its taste to resemble cider, but has a most disgusting smell, which, for a long time, prevents Europeans from tasting it. When accustomed to it, however, people become very fond of it, and account it healthy and nutritive. The cultivation of the plant which produces this liquor is of vast importance, both to the public revenue and to the comfort of individuals. It pays a duty on its introduction to the cities, and in the year 1793, the amount of the tax produced at the gates of the cities of Mexico, Toluca, and Puebla, amounted to near £. 200,000 Sterling. By distillation of pulque, a very intoxicating kind of brandy is produced, which, though prohibited by the laws,

Mexico. in order to favour the brandies of Spain, is of very extensive consumption. The plant from which the pulque is made has other valuable purposes to which it is adapted. It is used in making ropes, and even paper; it furnishes the inhabitants with a thread, called pita; its juice is used as a caustic to wounds; and its prickles serve the Indians for needles and pins.

The soil of some parts of Mexico is admirably adapted to the cultivation of tobacco, and perhaps in no portion of the globe is the consumption of that plant greater. It has been always a subject of taxation in every part of the Spanish dominions; but, in 1764, the royal monopoly, or farming of it, was introduced to this viceroyalty. Not only is it now necessary to obtain special permission to plant tobacco, but the whole growth must be carried to the royal farm, and paid for at a price to be fixed by the head of the department. It can only be raised in a district of four or five square leagues, and revenue officers traverse the country in all directions for the purpose of rooting up all the plants that are illegally cultivated. The consequence of these impolitic regulations has naturally tended to check production; and as sufficient is not raised for the consumption, the deficiency is supplied from provinces, where the expence of obtaining it is greater.

Sugar and rum are produced in New Spain, and, as before stated, want only good means of intercourse to increase most rapidly. As the cultivation of sugar is well known, it is needless here to give a description of it; but we cannot omit the striking result of a calculation made by Humboldt, viz. that all the sugar consumed in France, amounting to about 18,000 tons, might be produced on seven leagues square of land in the equinoctial regions. Cotton is grown in Mexico, but to an extent too limited to admit of any considerable exportation; the far greater part is appropriated to domestic consumption, and the whole sent to Spain is not valued at more than L.25,000. The quantity is not sufficient to supply New Spain, and it draws what it wants require from Guatemala and New Granada. Some valuable drugs are produced in Mexico, as sarsaparilla, jalap, vanilla, snakeroot, and some others, which, however important to the healing art, are of too little consequence to the agriculture or the commerce of the country to deserve detailed notices. Of dyeing drugs indigo is produced, but in very limited quantities, and scarcely more than sufficient for the few domestic manufactories. Cochineal is, however, a product exclusively hitherto Mexican, and deserves some attention. It was certainly cultivated long before America was known to Europeans. The cultivation of cochineal is at present limited to the intendancy of Oaxaca. Not more than fifty years ago, it was produced in the province of Yucatan; but on a single night, all the nopals, on which the cochineal insect lives, were cut down, and the breed consequently exterminated. The Indians assert, that this was done by the government, to increase the price of the stock on hand, and to confine the whole growth to the province of Misteca, in Oaxaca, where it is chiefly produced. The whites, on the other hand, aver that the Indians, irritated at the low price which the

merchants had fixed for cochineal, formed a combination, and destroyed at once both the insects and the plants on which they were reared. There are two species of cochineal, called *Grana fina* and *Grana silvestre*, one the wild, the other, if we may be allowed the term, the domesticated kind. The wild is found in several parts of the world, but though pains have been taken to introduce the better kind in many countries, they have hitherto been unsuccessful. The wild cochineal is covered with a cottony down, which prevents the rings on its back from being visible; the fine is distinguished by being covered with a mealy kind of white powder, which does not conceal the wrinkles on its back. Whether these two insects are of the same species is still a subject of doubt among the most acute entomologists. It is, however, certain, that they are bred on different plants, but yet it is ascertained that they couple together.

The nopal trees, on which the fine cochineal is bred, is of the cactus tribe, known by the name of the prickly tuna; but this variety has its fruit smaller, of an insipid taste, and white, instead of red. When designed to rear the cochineal insect, it is not suffered to grow to more than two feet in height. They are planted on land well cleared of weeds, and of other trees, which are usually burnt on the ground. The ground is cleaned twice in each year, and, if this be accurately executed, and the soil favourable, in the third year they become fit to rear the insects. In the months of April or May, the proprietors, called *Nopalcros*, purchase branches or joints of the *Tuna de Castilla*, with the young cochineals recently hatched upon them. These branches, though separated from their roots, preserve their moisture for several months. The Indians, who collect the young insects, keep them about three weeks, either in their huts or in caverns, where the branches to which they are attached are suspended under cover; after which they are exposed to the open air. The growth of these insects is rapid, and, in August and September, the mother cochineal have eggs not hatched, and are big with eggs a second time. Their laying continues from thirteen to fifteen days. In about four months after placing the cochineals on the nopals, the first harvest may be collected in the warmest situations, and in those a little cooler, though the insect is equally valuable, somewhat later. Much care is necessary in keeping the nopals clean, and Indian women sit down many hours to a single plant to brush them with the tail of the squirrel. The produce of the trees varies considerably; in some districts a pound of the semilla, sown in October, will yield a harvest of twelve pounds in January, and leave sufficient of the eggs to continue the produce till May, in which time they sometimes collect thirty-six pounds more. In other districts, where they are occasionally exposed to slight frosts, though great care is taken to cover the plants at night, they scarcely gather more than twelve pounds for each pound that has been sown. At the time of harvest, the insects are killed, sometimes by throwing them into boiling water, sometimes by placing them in heaps exposed to the burning sun, and sometimes in a kind of vapour bath. This last method is deemed the best,

Mexico. as it preserves the whitish powder on the body of the insect, which gives it an increased value in the estimation of the merchants at Vera Cruz and Cadiz. There are rigid laws to prevent the adulteration of this valuable commodity, but they are found to be insufficient wholly to stop the practice. It is, however, generally believed, that the mixture of other substances, where it is grown, is trifling in comparison with the additions made to it at Vera Cruz, and in the ports of Spain. The whole quantity exported from Mexico, *communibus annis*, was about 2,500,000 pounds, which, before the heavy duties imposed on it, both in Mexico and Spain, was not estimated at more than L.600,000. The quantity produced has greatly diminished of late years. The Indians have discovered, that other commodities pay them better for the labour of cultivating, and hence, in the last ten years, the produce is lessened nearly one half. The dyers of Europe have, however, found a substitute, so that, with the reduced supply, there has been no sensible increase in the price. Lac lake, a commodity from India, has in a great measure superseded it, both in England and France, and will probably, at no distant period, do so in other countries.

Bee-wax is an article of considerable importance in a country where the pomp of religious worship requires a great supply of wax-tapers. In the churches of the cities, and even of the Indian villages, the consumption is enormous. The indigenous bee of New Spain differs from that of Europe in having no sting, or at least none of sufficient strength to inflict the slightest wound. They are known by the name *Angelitos*, little angels. Their wax is abundant, but it is more difficult to bleach than that which is produced by the bee of Europe. Some of the Indians have farms of several hundred hives. Mexico does not produce sufficient wax for its own consumption, but obtains the requisite quantity from Cuba, where both the European bee and the American are carefully bred for the sake of the wax.

Besides the productions of agriculture, which have been enumerated, Mexico is abundantly supplied with animal wealth. When first discovered, the inhabitants had few or no domesticated animals. Europe has, however, furnished them with a few, which have become the rudiments of immense herds; they now cover many of the plains, and furnish to their inhabitants an ample supply of animal food. The tallow of their oxen suffices for all the manufactories of soap and candles; oil being too valuable to be used for the former of these purposes. Hides were formerly exported from Mexico to Spain, but, of late, the population and their wealth has so increased, that they are all converted into leather for their own consumption.

Sheep have never been encouraged, though the pastures are admirably adapted for their feed and propagation. The wool, which what few they have produce, is consumed in their manufactories; and as cotton cloths are better suited for the greater part of Mexico than woollen, we may attribute the neglect of sheep to that circumstance. Turkeys and ducks were originally sent to Europe from America, which, in return, received the common fowls of the Old Continent; but the common goose of Europe is not

yet to be found in any of the Spanish settlements in America.

Having enumerated the most important agricultural productions of Mexico, we must state, that though the principal branch of industry which has contributed to enrich the country, agriculture is still by no means in that state of activity to which it is capable of arriving. The indolence natural to man, when all his positive wants can be supplied with little exertion, must act as an impediment to the progress of agriculture, as well as of all the other arts. The want of roads, canals, and navigable rivers, whilst it continues, is an insuperable bar to great improvements; and, when to these are added the restrictions imposed by an impolitic government, we are rather surprised at the progress Mexico has made, than that she has made no greater. Amidst other impediments to her improvement, the want of capital is a most important one. It is so in every country, and peculiarly so here. The capitals acquired by mining have frequently been afterwards employed to give activity to agriculture, the only purpose to which capital can be beneficially applied in a country where little or no commerce exists. The convents, and other ecclesiastical communities, possess but little landed property. Their real wealth consisting of the accumulations from tithes, and other clerical sources, has been generally dedicated to agricultural improvements. The capital of the clerical bodies, amounting to more than L.10,000,000 Sterling, is lent out, in small sums, on interest, to proprietors of land, and secured by mortgages on their estates. The benefit conferred by such a capital applied to the agriculture,—a capital gradually increasing, must be very considerable. Such was the impression of its importance on the spot, that when, under the ministry of Godoy, orders were transmitted to Mexico to send these funds to Europe, it caused general murmurs; and though the viceroy had not sufficient firmness to defer, or to demonstrate the impolicy of executing the decree, but attempted to enforce it, the difficulty was so great, that in two years only the small sum of L.250,000 could be collected. One legal evil is felt in Mexico, as it is in Spain. The greater portion of the land, especially the larger tracts of it, is granted in what is called *Mayorazgos*, a species of entail which prevents alienation, or the division of land into smaller allotments, such as would be suitable for the purchase and the improvement of the class of small capitalists.

There is something very striking in the reports Minerals, and Produce of the Mines. which circulate in Europe of the wealth of Mexico and Peru; but perhaps the mineral wealth, which those countries furnish, has produced less effect on them than on the nations of the Old Continent, whose activity and intelligence has been forcibly stimulated by it. The mineral riches of Peru have been to no extent applied to sustain agricultural industry, which has languished in consequence. If Peru has not declined within the last century, she has certainly not advanced much in population or industry, in productions or in civilization. In Mexico, where the riches from the mines have stimulated agriculture, the progress has been considerable, more especially within the last forty years, in every thing that

Mexico. can conduce to the greatness or the prosperity of a country.

The whole quantity of gold produced in Mexico, on an average of several years, does not amount to more than 7000 marks, or 56,000 ounces, and is worth about £200,000 Sterling. This quantity is collected, either by washing the sands in the torrents which descend from the mountains, from some mines of small produce in the intendancy of Oaxaca, or from the silver mines, in which it is found combined with that metal. The silver which the mines of Mexico distribute over the globe is by far the most important part of what has recently been put in circulation. In a series of years at the beginning of the present century, according to the books of revenue by which the tax called the *fifth* is paid, the mean produce has been 22,170,000 piastres; and, estimating that portion on which the duty was evaded at somewhat less than a seventh part, we may consider the total at least as 25,000,000; worth, at the average rate of silver in Europe, £5,480,000 Sterling. This quantity exceeds the whole silver that is produced from all the other parts of America, whether belonging to Spain or Portugal.

The whole of the silver mines of Mexico are in the table-land, and most of them are at a great depth from the surface. They have been calculated to amount to nearly three thousand, and are divided into 450 districts, each governed by a council of the mines. It will be easily supposed, that, of these 3000 mines, some must be very inconsiderable, and some very unproductive, when it is ascertained that half of the silver raised in New Spain is the product of only three districts, viz. Guanaxuato, Catorce, and Zaccatecas. In fact, it appears that the whole of the mines do not pay an adequate profit for the capital that is employed in excavating and working them. On some of these undertakings the whole sum that is embarked is totally lost, and the works are abandoned. On others the product is for a long time much less than the expenditure; but they are continued with the hope that the proprietors will be so lucky as to meet with a rich vein of ore, that will repay them by immense wealth for the expence, trouble, and anxiety they have endured. Some of the mines, however, prove so enormously lucrative, that, like any other gambling, the adventurers are encouraged to continue the game as long as their money or their credit remains.

Working of
the Mines.

It is of great importance to the mines of Mexico, that, unlike those of South America, they are found in regions of moderate elevation and temperature. The greater portion of the most valuable are at the height of from 6000 to 10,000 feet above the level of the ocean, and, consequently, exempt from that severity of cold which is found so injurious in Peru. In consequence of the country round the mines being thus in healthy and fruitful elevations, the great number of labourers which they require easily find subsistence; and whenever an extensive mine flourishes, the concourse of people which it collects creates a market for food, to supply which, the uncultivated fields around them are brought to afford the requisite supplies; and towns spring up, and land becomes fruitful, where a few years before

only uncultivated deserts were to be seen. It is from the healthiness of the climate in which the mines are situated, and from the fertility of the land around them, that Mexico has been enabled to extract so great a quantity of mineral wealth, rather than to the richness of the ore, or to the accessibility of the veins. The mines of silver at Obergelberge, in Saxony, which are by no means excessively beneficial to the proprietors, will show how much the value of the mines of Mexico depend on the cheapness of labour, arising from the ease with which subsistence is obtained in a fruitful country. In each quintal of the Saxon ore that is extracted, they have commonly found ten ounces of silver, and in fortunate periods it has averaged fifteen ounces. The mean produce of the mine of Guanaxuato is four ounces in each quintal of ore. In other mines, the produce is from two to three ounces *per* quintal, and in few does it exceed five. The average is calculated by Humboldt at between three and four ounces. The mines of Mexico are much deeper than those of Saxony. Valenciana has a shaft of 1680 feet from whence to bring up the ore, whereas the richest of the Saxon mines, Himmelsfürst, is only 1100 feet in depth. The fruitfulness of the country around the mines is not the sole cause of their superiority, for though, as we have seen, the ore is by no means rich, yet the breadth of the veins in which it is found is highly favourable to the facility of raising it. A mine in Saxony, where the vein is six feet in extent, is considered as a prodigy, but the (*veta madre*), mother vein of Guanaxuato, is from 130 to 145 feet in extent. The Saxon mine has been worked in length about 700 yards, whilst the broader one in Mexico has proceeded already to double that distance. The extent and length of other veins are of the same extraordinary dimensions, and the smaller veins, which in Europe would be worked, are left in total neglect. The use of machinery to diminish animal labour is but feebly adopted, and the execution of those few machines they construct is so bad, that they are scarcely of any benefit. As the ore is brought from the mine on the backs of men, it is necessary that the descent should be made very capacious. That of the mine Valenciana is 1680 feet in perpendicular depth, and 90 feet in circumference. This pit is dug in the solid rock, it is beautifully walled, and, when completed, having cost a million dollars, may be considered one of the greatest and boldest undertakings in the history even of Mexican mining. This mine has the peculiar property of being free from water, a circumstance of vast importance, since other mines, equally rich, have been abandoned, because the proprietors have not been enabled to exclude the water, where the steam engine is not yet adopted. In the year 1760, the country around this mine was a perfect desert. M. Obregon, a Spaniard, with a vehement passion for mining, with a small capital, but with the confidence of richer men who assisted him, began to excavate. In 1766, though he had got to the depth of 260 feet, the value of the produce was less than the current expences. He then entered into partnership with a small trader, named Otero, who had some ready money. They continued to pursue

Mexico.

Mexico. their operations, with confidence in the result, till, in 1771, they came to masses of sulphuretted silver, mixed with native and red silver. From 1771 to 1804, the mine has constantly yielded a gross produce of L. 583,000 Sterling; and in some of the most profitable years, the two proprietors have each shared the enormous sum of L. 250,000. The spot where these operations commenced was occupied by a few wild goats, and in ten years it became a considerable town, with seven or eight thousand inhabitants, surrounded with cultivated and highly productive fields. As the miners have gone deeper for the ore, the expences of raising it have been increased; but the quality has so improved, that the net profit to the proprietors has continued the same. The expence of working this mine amounts annually to L. 190,000 Sterling; three-fourths of which are for wages to the labourers, and the remainder for gunpowder, steel, iron, wood, leather, and tools of various kinds. The cost of powder for blasting the rocks amounts to L. 16,000 annually. The number of individuals employed is about 3000. The principal manager receives a salary of L. 2500, and has under him several overseers, and nine master miners. These head men visit daily the subterraneous operations, on the backs of men, who have a kind of saddle for the purpose, and are called little horses (*cavalitos*).

The whole of the labour of the mines is performed by freemen; no slaves or convicts are employed; and the stories circulated in Europe of criminals and smugglers being condemned to labour in the mines are totally without foundation. The labour, though voluntary, is very severe, and the people are stimulated to perform it only by being paid, not by the time occupied, but by the quantity of work that is performed. The ore is carried solely by men, who are so accustomed to this kind of labour, that they remain with a load from 240 to 370 pounds on their backs six hours at a time, during which they ascend many thousand steps in the pits, in a temperature from 71° to 77° of Fahrenheit. They proceed in files of fifty or sixty, among whom are some boys of ten or twelve years old, and some men more than sixty, each of them loaded according to his own estimation of his strength. In ascending the stairs they throw the body forward, and support themselves with a staff about a foot long. They walk in a zig-zag direction, having found by experience that their respiration is thereby less impeded. The muscular strength acquired by these men must be prodigious, since, without any burden, a person not accustomed to it, feels intolerably fatigued from ascending and descending so many thousand steps. The weight of each load is agreed on before the ascent is begun; regular registers of the quantity carried by each individual is entered by accountants; and the quantity of ore brought from the mine is easily ascertained to the satisfaction of all parties. Each digger of the ore is calculated to loosen as much from the vein as three of the porters can carry away. This operation is performed with a kind of iron crow, with a sharpened steel point, that requires perpetual repointing; for which purpose small moveable forges are placed in various parts of the mines. Though the workmen are almost naked, and are closely

watched and carefully searched, they sometimes contrive to embezzle considerable portions of the richest minerals, by concealing them in their hair, under their arms, and other parts of the body. These thefts are often detected, and a register is kept of what is thus seized from the depredators. In the mine of Valenciana it amounted, in fourteen years, to the value of L. 36,000 Sterling.

Though the mine of Valenciana has produced the most uniform profit to its owners, that of Sombrete, in the intendancy of Zaccatecas, has produced the largest profit in a short period. A portion of this mine, called (*veta negra*), the black vein, yielded to its proprietors, the family of the Marquis del Apartado, upwards of L. 800,000 Sterling within six months; and though nothing approaching to that profit has since been gained, it still holds its rank among the mines of the first class. The mines of Catorce have been begun but recently to be excavated. This district was first explored by an accurate and adventurous miner, in 1778. He was fortunate enough, at the first trial, to hit on what is called the great vein (*veta grande*), and in a very short time gained more than half a million dollars by it. The great riches of the vein, however, were not developed till it had been carried 350 feet down, whence, to the depth of 550 feet, they found the metals called *colorades*, a mixture of silver and gold, and abundance of native silver. At that period the expence of working scarcely exceeded 80,000 dollars, whilst the value of the metals amounted to 1,200,000. This vein is of the extraordinary breadth of 130 feet. It continued highly productive till 1798, when it had reached a depth of 1574 feet; since that time the mineral has become less valuable, the *metales colorades* have disappeared, and pyritous and coppery minerals are found with the silver. It is, however, still worked to considerable profit, but not to the extraordinary advantage which was yielded between 1778 and 1798.

When the ore is brought to the surface, there are two modes of separating the minerals from the substances in which they are incorporated; smelting and amalgamation. The first of these processes is so familiar, as to need no description, being nearly the same as is applied to all other minerals. It is used in Mexico in not more than one-third of the mines; and if the uncertainty of obtaining sufficient mercury was removed, and the price of that commodity properly reduced, it would be practised in still fewer, especially as the wood required for firing is becoming scarce on the ridge of the Cordilleras, the most populous of the mining countries. As the scarcity of wood increases, the abolition of the process of smelting will become an object of considerable importance to the various manufactories that are carried on in that district. The progress of amalgamation depends on the quantity of mercury that can be conveyed to the mines, and as a naval war intercepts the supply, that process is necessarily greater in time of peace. In the process of amalgamation, the first step is to reduce the ore to a fine powder, which is done by well constructed mills. As the adhesion of the particles to the quicksilver depends on their fineness, this opera-

Mexico.

Mexico.

tion is more attended to than any other. The powdered ore is moistened, and in that state, called *schlich*, is carried to the court of amalgamation, an open space paved with hard flag stones. The floor is covered with the *schlich*, and levelled so as to form a heap from 60 to 90 feet in length, and about two feet in thickness. The materials for amalgamation are then added to it, and consist of muriate of soda or common salt, sulphate of iron and copper, lime and vegetable ashes. The salt is first applied, the quantity of which varies with its purity, which is very various, sometimes amounting to twenty, and sometimes to not more than four pounds, for every quintal of the mineral paste. The mineral, thus mixed with the salt, is left for several days till the whole of the latter is supposed to be dissolved and equally distributed. If the metal is then deemed too warm, or in a state of oxidation, and charged either with sulphates of iron and copper, which rapidly decompose in the air with muriate of silver, lime is added to cool the mass. But if the paste is thought too cold, as it will be, if it contains sulphate of lead or pyrites, which decompose with difficulty in humid air, sulphate of iron and copper are added, which are known to heat the composition. This is thought necessary, and it is only considered to be well prepared when a sensation of heat is felt by holding it in the hand. After leaving the mixture some days to repose, the mercury is begun to be incorporated with it. The quantity of mercury is fixed by the estimation made of the quantity of silver which the composition will yield, and they usually add to the mixture about six times the weight of quicksilver, which they expect will be produced in pure silver. Shortly after the addition of the mercury, sulphate of iron and copper are administered to it again, if too cold, or lime, if too hot. During the space of three, four, or even five months, its temperature is watched, and corrected by the application of the lime, or the sulphates, as either one or the other may be required to make the mercury act on the silver. During the whole of this part of the operation, the action is favoured, and the union increased, by stirring the materials. This is usually done, by causing twenty or thirty horses, or mules, to run round for several hours, or by setting workmen to tread the mass, who go for whole days barefooted in this metallic mud. When it is known by the appearance of the mass, of which those accustomed to the process are accurate judges, that the mercury has united with all the particles of the silver contained in the mixture, the metallic muds are thrown into large vats of wood or stone. Small mills, provided with sails, placed perpendicularly, turn round in those vats. A stream passes through them, by which the earthy and oxidated parts are carried away, whilst the mercury and the amalgam remain in the bottom of the vat. The amalgam remaining at the bottom of the vat is then, in some measure, discharged of the mercury, by pressing it through sacks. The amalgam is then moulded into a pyramidal form, and, in that state, goes through the process of distillation, by which the remainder of the mercury is evaporated, afterwards condensed, and preserved for future use. In this process, however, a loss of mer-

Mexico.

cury is suffered, generally from an ounce and a half to an ounce and three quarters for each ounce of silver that is produced. Our business here is to describe the process, not to point out its errors, or to show that the same effect might be produced in a less expensive, and far more expeditious manner. Among so many thousand mines, the owners of which are the most independent of mankind, there are to be found many deviations from this mode of amalgamation, but we have described that mostly followed, without examining, with chemical criticism, the effect which would be produced if the mass of *schlich* was placed in a court paved with iron and copper instead of stone, or if the process of stirring would be more beneficially performed with ploughs of iron or copper, than by the feet of horses, mules, or men. This has been urged in Mexico, and will probably be adopted as soon as the benefit of it is clearly understood. The method of amalgamation has been the cause of the increase of the Mexican mines. By it, all the silver in the ore may be extracted from it, and now the residuum, which, under the former process, used to be thrown away as of no value, is made to produce a quantity of silver, that amply repays the expence of collecting it.

Since this mode has been adopted, the consideration of the quantity of mercury that can be procured becomes of vast importance. The present consumption of Mexico requires a supply of 16,000 quintals, which, in time of peace, is supplied from Europe. The mine of Almaden, in Spain, would have furnished this quantity, but for an inundation, which, for want of timely attention, destroyed the works. The mine of Huancavelica, from similar carelessness, had ceased to be worked, or produced but little. In these circumstances, the court of Madrid made a contract with the Austrian government, for a supply to be furnished from the mines of Istria. The mercury from Germany either was, or was supposed to be, less pure than that of Almaden. The government of Spain have unwisely made quicksilver the subject of a royal monopoly, and an article of revenue. The price is thus raised, and the supply uncertain. Intrigues are carried on by the miners at the viceroyal court of Mexico, either to obtain a large quantity, or a greater proportion of Spanish than German quicksilver; and these smaller proprietors, who either have no access to the court, or have no means of creating an influence there, are compelled to be satisfied with a small portion, and that portion what is deemed of the inferior quality. The power of the viceroy to distribute quicksilver whenever it has been scarce, has been the means of great oppression on many miners, and a source of wealth, scandalously enormous, to the viceroys. The price at which the court of Madrid supplies its provinces with quicksilver is of vast importance, both to their and her own prosperity; whereas the revenue drawn from the monopoly is impolitic in its principle, corrupt in its practice, and small in its amount. The court has, indeed, gradually reduced the monopoly price from 82 to 41 dollars the quintal, a price, perhaps, as low as the consumers could obtain it on an average of years, if a competition was permitted. The great evil now arises from the favouritism by which the interests of the

Mexico. small proprietors are sacrificed to those of the greater. It is also no inconsiderable evil, that a supply proceeding from only one source, and that not the most unexceptionable, must be very uncertain, and often very scanty. In New Spain, the indications of mercury are very visible. Cinnabar is found in many parts, and sulphureted mercury in others; but these mines have engaged little attention, and the monopoly of the government has acted as a bar to their being effectually investigated.

Although the mines of Mexico are all of them the property of individuals, or of voluntary partnerships, yet they have a bond of union in a tribunal or corporation, which makes laws to regulate the rights created by the mining system, and (though they can only recommend) to institute improvements in the various processes. When, at the early period of the occupation of Mexico, the Spaniards first began their mining operations, a mixture of laws, some Spanish, some German, and some Flemish, emanated from the court of the Emperor Charles the Fifth. Their contradictory nature induced the proprietors of mines to form a board, which at first was a voluntary union, but has since been recognized as a legal corporation, endowed with considerable revenues, and invested with extensive authority. The board called *Tribunal General de la Minería de Nueva España* is composed of a director, two deputies from the provincial councils of miners, an assessor, two consultants, and a judge. They are chosen by the thirty-seven provincial councils of the miners, and have two deputies constantly residing at Madrid to protect their interests at the seat of government. They direct the studies in the College of the Mines, and select from thence students, who are sent for the purpose of communicating instruction to the chief towns in the mining districts. The influence of these students is, however, confined; they have no power to direct the most beneficial processes; and the jealousy of the miners regarding their liberty prevents the full benefit which might be derived from this diffusion of men of scientific acquirements. The institution of the tribunal, especially under the organization it has received within the last forty years, has been of great benefit to the proprietors of mines. It has preserved a degree of public spirit, disseminated the knowledge of new facts and improvements, and created a community of feeling among all those connected with the important affairs of the mines. This board is endowed with an annual income of more than L.40,000 Sterling, arising from the signorage which is divided between it and the crown, on all the gold and silver coined at the royal mints. The revenue was designed to support the School of Mines, and to be lent out to feeble proprietors, to assist their operations. It has been useful, to some extent, in both ways; but the court of Madrid, in the state of poverty which has compelled it to lay its grasp on money wherever it could be found, has extorted, under pretence of a gratuity and a loan, near L.700,000, which has absorbed more than its accumulation, and now one-half of its revenue is destined to pay the interest of money which has been borrowed to lend to the government.

The taxes levied on the mines are weighty, and

produce a revenue, which, though much evaded, is still very large. Formerly the king received a fifth of the produce of all mines, and though this tax has been reduced to half that proportion, it still retains its ancient name *el quinto*. The quinto is now 10 per cent.; another duty called the 1 per cent. is added; besides which, for coinage and seniorage, including the share of the tribunal of mines, 2½ per cent. is paid; making together a charge on the proprietors of 13½ per cent. on the amount of the gold or silver that is extracted. Considerable intricacy exists on this subject. When the minerals contain, as they frequently do, a mixture of gold and silver, this gives rise to endless discussions, and opens a field for oppression, for bribery, for chicane and corruption, which ultimately tends to enrich the larger proprietors in some degree, and the officers of the revenue in a much greater.

Besides the more precious metals, gold and silver, which we have thus far exclusively viewed, Mexico abounds in the other mineral riches, which equally contribute to the improvement and enjoyments of man in the social state. Iron is found in great abundance in the intendancies of Valladolid, Zaccatecas, and Guadalajara, and especially in the more northern provinces. The increased production of these mines is always suspended by a return of peace, however much they may have yielded in the preceding periods of war. The difference in price in war and peace, both in iron and steel, is enormous. The former has sometimes risen from 20 to 240 the quintal, and the latter, which commonly in peace was sold for L.3, has been known in war to be worth L.50. During the early part of the wars occasioned by the French Revolution, the tribunal of mines advanced money to the iron miners, but the works were suspended by the peace of Amiens. When war recommenced, these mines were resumed, but very imperfectly, and the tribunal having lent its capital to the government, could offer them no assistance.

Copper is found in a native state in the intendancy of Valladolid, and some in Guanaxuato. Tin is found in mines, but is principally extracted from the earth washed down in the deep ravines. A combination of these two metals, both of which were known to the ancient Mexicans, though they had not discovered iron, was used to form their tools and weapons. By an examination of one of their implements by some French chemists, it was ascertained that they had the art of tempering these two metals, so as to render them equal in effective utility to iron, or even steel. Lead is found, but the mines are very little worked. Zinc is found under the form of a brown and black blende in several veins. Antimony is produced in Catorce; arsenic, combined with sulphur, has been extracted from the minerals found in Zimapan. Neither cobalt nor manganese has yet been discovered in Mexico; and both these minerals, though the latter has been discovered in Cuba, appear to be less abundant in the equinoctial regions of America than in the temperate climates of the ancient continent. To complete our view of the minerals of New Spain, it is necessary to state, that coal mines have been discovered in several parts of the

Mexico.

Mexico.

northern provinces, and one is slightly worked near the sources of Rio Sabina. Rock salt is also found in many parts; and, if necessary, more might be obtained. It is principally required for the process of amalgamation in the silver mines, as the Indians scarcely use it with their food, but adhere to their ancient practice of applying the Chili as the sole condiment to their food.

Revenues

New Spain, unlike the colonies of the other European nations, not only produces a revenue adequate to the expence of its own government, but a surplus to assist the mother country. Owing to the very impolitic arrangements of the government, the expences of its collection amount to more than one-fourth of the gross sum of the revenue. The taxes levied on the mines are the most productive; these have been before described, and amount, on an average of years, to

Net profit of the mints, 1,500,000
Profit on the sale of mercury, 536,000

5,552,000

The monopoly of tobacco, after deducting the expence of the cost of the leaf tobacco, is 594,000 dollars; and that of manufacturing it into snuff and segars, which is 1,285,000 dollars, produces 4,500,000 dollars; but this particular branch of revenue is reserved to the crown, and not mixed with the general produce of the taxes, but remitted to Spain in a distinct head of account. The alcavala, or duty on sales, from which the Indians are exempted, produces net about 3,000,000. The Indian capitation tax yields 1,300,000. The duty on the fermented liquor made from the Agava, called Pulque, produces 800,000. The Almoharifazgo, or duties on foreign trade, is 500,000. There are some other articles, which we shall presently enumerate; but in the mean time we must mention, that the king has a monopoly of *fighting cocks*, and of *snow* from the mountains, which, whimsical as it may appear, are both thereby subjected to taxation, and this tax, though trifling, is found very irritating to those who love a barbarous amusement, and to those who wish to enjoy cool liquors under a burning sun.

Dollars, 16,727,000

Mexico

By some accounts, it appears, that, when the gross revenue of New Spain amounted to 20,000,000, the expences of collecting it were more than 6,000,000, and, consequently, the net sum paid into the treasury was less than 14,000,000. It should, however, be remarked, that, in the expences of collecting are included the salaries of the viceroy, of the intendants of the provinces, of the different secretaries and clerks, and the pensions of governors retired from office, and all the expences, except those of the military kind, and those of the courts of justice. The revenue of 16,727,000 dollars first pays the military, naval, and judiciary charges; the repairs of fortifications, arsenals, hospitals, and other royal works, 5,700,000 dollars. The other settlements in America, whose revenues fall short of their expenditure, draw from the treasury of Mexico the requisite sums. Florida, Porto Rico, Cuba, Manilla, and St Domingo, draw from New Spain about 3,500,000 dollars annually; and the remainder, about 7,000,000½ dollars, or L. 1,700,000 Sterling, is remitted to the court of Madrid.

From the gross amount of the revenue is, however, to be deducted the salary of the Viceroy. This is the annual sum of 60,000 dollars, which, large as it appears, is of itself inadequate to the state he is compelled to assume, and the expences he consequently incurs. He cannot move without his guards on horseback, most splendidly accoutred; he is constantly served by pages of honour; is forbidden by etiquette from permitting any but his own family to sit at table with him; and preserves constantly more of the state of a monarch than is retained by most of the sovereigns of Europe. He has few honourable and fair means of accumulating a fortune, and hence the few who have filled the office with a desire to benefit the community have retired from the dignity with their original mediocrity. On the other hand, their extensive power has been used by many to enrich themselves, and that to a degree that might satisfy cupidity itself. Some individuals have returned to Spain, after filling the office of Viceroy for a few years, with fortunes of from L. 300,000 to half a million Sterling. The distribution of mercury, the patronage of lucrative places, the dispensing rank in the militia, the recommendation of individuals to the titles of count or marquis, the opening the ports to favour the commercial speculations of individuals, and the winking at contraband transactions; all these ways may be, and often have been, used by Viceroys to the injury of the public, and the pecuniary advantage of their own families. In order to escape inquiry at home, it is necessary that he should have a most intrepid assessor with him, and a powerful party in the court of Madrid; and, with these assistants, there is no knowing the bounds to which his corruptions may be extended.

None of the officers of government have any effectual control over the Viceroy. The court of royal audience, a kind of privy council, and the supreme court of justice, may indeed protest against his acts, and transmit their protests to the Council of the Indies in Spain, but it must obey his orders,

Mexico. without creating delay, how much soever it may condemn them.

Armed Force. An army is constantly kept up in Mexico of about 10,000 regular troops, who are recruited, disciplined, and regimented, within the viceroyalty. Of these about 6000 are in Mexico proper, and the remainder on the various stations on the northern frontier, or in the *provincias internas*. Of the former 1000 are cavalry, 150 artillery, and the remainder infantry. The regular troops on the frontier provinces are mostly light troops, with some flying artillery. Besides these regulars, called *tropas veteranas*, a body of militia (*milicias provinciales*) of 22,200 men is constantly maintained; of these 11,000 are infantry, and the same number of cavalry. The Indians on the banks of the Rio del Norte carry on a constant war with the Spaniards. The troops on that frontier are, in consequence, in a state of perpetual activity. They are all natives of the country. They are tall and robust mountaineers, admirably mounted, and equally accustomed to the extremes of heat and cold. They are constantly under arms, generally on horseback, and perform long marches through deserts with no other provision than a little ground maize, which they mix at any brook with water, and thus subsist without difficulty. It is reported by those who have seen these troops, that it would be difficult to find in Europe any cavalry of greater activity in its movements, of greater impetuosity in battle, or capable of enduring greater privations. As these would be the first troops to be encountered, in case hostilities between the United States and Spain should lead to an invasion of New Spain by the former, they are entitled to this brief notice. Almost the whole frontier towards the United States is by nature nearly impenetrable. Arid savannas, resembling the deserts of Tartary, separate the provinces of Mexico from the United States. Beyond the 32d degree of north latitude the extent of the deserts and the nature of the soil afford security against an invading enemy. To the southward, between the Mississippi and Rio del Norte, several rivers intervene. The ground towards the shore is swampy, and these swamps filled with impenetrable thickets. On this point the two countries at present approach nearest to each other; the American post Fort Clayborn is distant from the Spanish presidio of Nacodoches only about sixty leagues.

Ecclesiastical Establishments. Although the religious establishment in Spain is most profusely endowed, that example has not been followed in Mexico to so considerable an extent. The numbers of the clergy bear a proportion nearer to the Protestant than to the Catholic countries of Europe. The Archbishop of Mexico is the metropolitan, and has under him eight bishops, the differences in whose revenues are very striking.

The inequality of income seen in the bishopricks extends also to the curas or parochial clergy, some of whom have incomes amounting to 15,000 dollars, whilst others have scarcely 100. The religious houses are in many instances rich, but not from their possessions in land, so much as from their accumulations which have been improved by lending on mortgages to the proprietors of lands at high interest. The revenues of the church being derived almost solely from land, in the form of tithes, have partaken of that advance which the increase of cultivation has produced. The difference in the value of tithes taken at two following periods, will show both the increase in cultivation, and in the revenues of the church. Produce of tithes from 1771 to 1780, 13,357,157 dollars,—from 1781 to 1790, 18,353,821 dollars.

The proportion between the regular and secular clergy is not ascertained, but the whole of the religious of both orders, including nuns, monks, lay-brothers, probationers, choristers, and servants, do not exceed 14,000 persons.

The political division of New Spain is into twelve Intendancies, to which may be added three provinces and Provinces, which, though under its government, are removed to a considerable distance, and are rather dependant upon it, because no other plan of ruling them has yet been adopted, than from any design that they should ultimately be considered a part of it. The intendancies are,

Mexico	Oaxaca
Puebla	Merida
Guanaxuato	Vera Cruz
Valladolid	San Luis Potosi
Guadalajara	Durango
Zacatecas	Sonora.

After a sketch of these, the provinces of New Mexico, Old California, and New California, will be noticed.

The intendancy of Mexico merits the first consideration, on account of its being the most populous, the most rich, and as containing the capital of the kingdom, and the seat of the government. Its extent is 5927 square leagues, and its inhabitants, by the census of 1803, amounted to 1,511,800. It extends from 16° 34' to 21° 57' of north latitude. On its western side a portion of the province is washed by the South Sea from Acapulco to Zacatula, a distance of 270 miles, but no part of it approaches nearer than 35 miles to the Eastern Ocean. The intendancy being both on the high and the low land, must partake of the climate of each, but more than two-thirds of it is mountainous, and consequently cool and healthy; whilst that part which borders on the South Sea, has all the heat and insalubrity usually encountered in similar circumstances. Only the highest peak of one of its mountains enters the region of perpetual snow; and no other summit but

Mexico.

this of Toluca is equal in height to Mont Blanc in Switzerland. The best and most valuable portion of the intendancy is the Valley of Mexico, which is called a valley, because surrounded by ridges of higher hills, but is yet 7500 feet above the level of the ocean. The drains of the hills around the plain run towards the city, in the vicinity of which they form the lakes of Tezcuco, Zumpango, San Christoval, Xochimilco, and Chalco. Tezcuco, from the muriate and carbonate of soda in the soil, is brackish; the other lakes are of good tasted water, and all are abundantly stocked with fish. These lakes have gradually been drying up, ever since the country has been occupied by the Spaniards. The great quantity of trees which have been cut down for building, whilst none have been planted, has exposed both the soil and the lakes to a greater degree of evaporation, as well by a greater surface on which the direct rays of the sun operate, as by laying them open to the influence of the drying winds from the south. Artificial means have been also applied to a most expensive, if not an effectual extent, for draining the Lake of Tezcuco, and preventing it from inundating the capital, as it has sometimes done in a most injurious degree. Operations have been carrying on for near 300 years to prevent these inundations, by turning the Lake of Zumpango into a stream, that shall empty itself by the River Tula to the Gulf of Mexico. The labour, and even the lives, of numberless Indians have been lavished on this undertaking, and the expenditure has already amounted to £2,000,000 Sterling. It is a canal of most stupendous dimensions; but from the friable nature of the soil through which it is conducted, from frequent variations in the design, and numerous errors in the execution, it does not yet operate as an effectual security, or insure the inhabitants from these fatal inundations, by which at several periods they have been visited. The lakes in the immediate vicinity of the capital are made to supply considerable quantities of vegetables and fruits, by means of floating gardens; an invention of more importance, when the city was almost covered, and wholly surrounded with water, than at present; but which has, however, been continued by the Indian families to the present time, and furnishes the means of subsistence to many of them. These gardens (*chinampas*) are formed of reeds, rushes, roots, and branches of brush-wood, which are converted into a raft; on these materials is laid the black mould, which is strongly impregnated with muriate of soda. The soil is gradually purified from the salt, by frequently washing it with the water of the lake. Even the water of Tezcuco, which, though salt, is not highly saturated, has the effect of dissolving the salt in the soil, and by each washing the fertility is increased. Some of these gardens contain the cottage of the proprietor, on which he guards a group of surrounding chinampas. They are towed or pushed by long poles from one part of the lake to the other, and in process of time, as the lakes have subsided near the banks, these gardens have become fixed, and at length, by farther fall of the water, have become dry ground. Each chinampa is about 330 feet long, and 20 broad. The mould, purified by frequent irrigations, is heap-

ed to the height of three or four feet above the surface of the water. Beans, peas, capsicums, potatoes, artichokes, cauliflowers, and other vegetables, are cultivated upon them; the borders are generally ornamented with flowers, and sometimes a hedge of rose bushes is planted as a fence around them. One of the most agreeable recreations of the inhabitants of the city is taking the air in boats among these delicious floating gardens.

Mexico.

The city of Mexico, the most extensive, populous, and wealthy of any place in the western hemisphere, is built on what was formerly a lake, and is still a marshy soil, between the two lakes of Tezcuco and Xochimilco. The centre of the city is distant from the former two miles and six furlongs, and from the latter five miles and a half. It equals in regularity of buildings, in equality of surface, and in the breadth of its streets, St Petersburg, Berlin, or the best parts of Westminster. The houses are built of stone, with flat roofs, and generally display considerable architectural taste. The public buildings are magnificent, and have been constructed at enormous expense. The most considerable of these is the Viceroyal Palace, an extensive but heavy edifice; the Cathedral, a magnificent building, whose execution occupied ninety years, and which is most profusely adorned with gold and silver images, rails and lamps of solid silver, and other decorations of the same expensive character. There are near one hundred other churches, which are for the most part ornamented and decorated with the same lavish profusion. The Royal Mint is a splendid building, and one hundred workmen are constantly employed in it. The edifice destined for the School of Mines cost in building £125,000, and would be thought an ornament to the best parts of Paris or London. The Plaza Major is adorned with a beautiful equestrian statue of King Charles the Fourth, cast in bronze in this city by a native artist. It is considered a *chef d'oeuvre* of art, and its weight, which is twenty-two tons, must have employed mechanical talents of no common order to place it on the pedestal which supports it. The Treasury near the Viceroy's palace is more remarkable for having been the spot from whence have issued more than one thousand five hundred millions of dollars, than for any peculiar beauty or taste in the edifice. There are many Convents in the city, the principal one, that of the Franciscans, is of great extent, and possesses a large revenue. There are several Nunneries, the principal part of whose inhabitants are the females of the higher Indian families, and some few of the white Creoles.

Education is not totally neglected, though it is rather at a low ebb. The University is a richly endowed establishment, and has abundance of professors, canons, and the other offices which might be usefully employed. The mathematics, chemistry, and botany, are more studied than the classics, but scholastic divinity is the most favourite pursuit, in an institution whose principal design it is to qualify youth for the clerical profession. The study of mineralogy is prosecuted with ardour in the school for that science. A botanical garden is established, very richly furnished with the rarest specimens of those plants which are interesting either to commerce or medicine. An Aca-

State of Science and Learning.

Mexico. demy for the Fine Arts, furnished with a good collection of ancient casts, has been useful in fostering a correct taste, which has been displayed in the equestrian statue already noticed, and in a beautiful sepulchral monument consecrated to Cortez by his descendant the Duke of Monteleon, which was constructed by Tolsa, and stands in the chapel of the hospital *de los naturales*. Instruction in the fine arts is communicated *gratis*, and for this purpose an annual revenue of more than L.5000 is appropriated. The building assigned to it contains a much finer assemblage of casts than is to be found in any city of Germany. Casts of the Apollo Belvedere, Laocoon, and other large statues, have been transported over the worst roads, and over higher mountains than St Gothard or St Bernard. The casts were purchased in Europe at an expence of more than L.8000, exclusive of the cost of conveyance. The Academy has laboured successfully to introduce among the artisans a taste for elegant and beautiful forms. Every evening the large rooms of the building, well lighted with Argand's lamps, are filled with hundreds of young people, some of whom are occupied in drawing from relieves or living models, and others in copying drawings of various kinds; and in this assemblage the distinctions of rank depending on complexion seem to be waved, as the whites, the Indians, and the Mestizoes, meet on equal terms, and enjoy equal advantages of instruction.

The knowledge of chemistry is very generally diffused throughout Mexico; it is called the *nueva filosofia*, and the natives even in the distant provinces are accustomed to reason on its principles and results. The best work on mineralogy in the Spanish language, *The Manual of Oryctology*, according to the principles of the school of Freyberg, by M. del Rio, was published in Mexico, as well as the first translation of Lavoisier's *Elements of Chemistry*. The School of Mines possesses a chemical laboratory, a geological collection arranged according to the system of Werner, a physical cabinet furnished with the instruments of Ramsden, Adams, Le Noir, and Berthoud, and also models executed with great accuracy by native artisans. The Court of Spain has sedulously promoted botanical researches in each portion of its extensive transatlantic dominions. The botanical garden in Mexico exhibits specimens of these expeditions. One of the commissioners for New Spain, M. Sesse, after returning from the expedition, and arranging his collection, delivered a course of botanical lectures, which are now continued by M. Cervantes, whilst M. Echeveria describes the extraordinary beasts, birds, and fishes, which the country produces. These gentlemen are both of them natives of Mexico.

Mathematical knowledge, though not neglected, is less assiduously cultivated in the University of Mexico than in the School of Mines. The pupils of this last institution proceed farther in analysis, and are instructed in the integral and differential calculus. As the return of peace has supplied them with chronometers, sextants, and repeating circles, we may hope for accurate observations from the most remote provinces of the viceroyalty. The taste for

Mexico. astronomy is of ancient date in Mexico. It had three distinguished cultivators in the last century,—Velasquez, Gama, and Alzate. They made a number of observations, especially on the eclipses of Jupiter's satellites. Alzate was the correspondent of the *Academy of Sciences in Paris*, and though, from directing his attention to too many objects, he sometimes was led into error, he is entitled to great praise for having excited among his countrymen a taste for science, and a love of research, and for having diffused a considerable portion of physical knowledge by the *Gazetta de Literatura*, which, for a long series of years, he edited.

Don Joaquin Velasquez was the most able geometer that has been produced in New Spain, and all his geodetical and astronomical labours bear the stamp of the greatest accuracy. He was born in July 1732, at an obscure Indian village. His uncle, a parish priest, placed him under an Indian of Xaltocam, who was deeply versed in the Mexican history and mythology, for his education, where he acquired a knowledge of the various languages of the indigenous inhabitants, and perused their hieroglyphical writings. He was removed to the Tridentine College in Mexico, which then had a paucity of books, instruments, and able instructors. With such assistance as he had, however, he commenced the study of the mathematics, and was at length made happy by an accident, which placed in his hands the works of Bacon and Newton. From the one he imbibed a taste for astronomy, and from the other learnt the true method of philosophizing. Being then poor, he began jointly with his friend Guadaluara, since Professor of Mathematics in the Academy, to construct telescopes, quadrants, and other instruments. Having entered on the profession of the law, the fees he received as an advocate were destined to procure from England those instruments which his love of science made desirable. He continued his studies with much assiduity, and was at length appointed a professor in the University. In 1769, he was appointed to observe, in California, the transit of Venus, and to make other astronomical observations. He rectified the errors in the geographical positions of various places in that country, and availed himself of its translucent and serene atmosphere, to make several celestial observations. The Abbe Chappe, from Paris, had arrived in California during his residence there, to observe the transit of Venus, and was surprised that the Mexican astronomer was found right in having ascertained that the eclipse of the moon on the 18th of June would be visible in California, contrary to his own calculation. He made by himself a very good observation of the transit of Venus over the disk of the sun, 3d June 1769, and communicated the result the same morning to Chappe, and to the two Spanish astronomers, who were his fellow commissioners. In 1772, by a variety of observations, he fixed the latitude and longitude of the capital, and many other important places in the viceroyalty. His labours were indefatigable, and the establishment of the School of Mines, which owes its origin to him, will be a lasting monument of his zeal and ardour in the cause of science. He died in 1786, whilst director-general of the Tri-

Mexico. *lunal de Minería*, and invested with the title of *Alcalde del Corte Honorario*.

After these notices, it would be unjust not to mention Gama. Without fortune, and with a numerous family to maintain by severe and almost mechanical labour, he was unknown during his life to his fellow citizens, though they eulogised him after his death. Gama, by his own exertions, became an able and well informed astronomer. He published several memoirs on eclipses of the moon, on the satellites of Jupiter, on the almanack and chronology of the ancient Mexicans, and on the climate of New Spain; all of which discover great precision of ideas, and great accuracy of observation.—It is proper to record these instances of mental proficiency, both as preserving the memory of respectable individuals, and showing that the western hemisphere is capable of producing and developing talent.

Police, P/
population.

The *Acordada*, a prison and house of correction, is a very fine and extensive building. It has room for more than 1200 inhabitants, many of whom are destined to reside there, for contravening the revenue laws, and for other offences. Besides the hospital of St Juan de Dios, which, being under the care of the monks, as in the other Spanish dominions, is not considered to receive the best medical treatment; there are several other hospitals, which receive the sick poor, and to which students in medicine are admitted, to acquire the knowledge of their profession. The streets of Mexico are well paved with a most excellent kind of porphyry, and it is well lighted with convex lamps. A common sewer runs through the centre of each street, which is covered with planks, and conveys the filth of the city away. A very good police is maintained, under the direction of the *Cabildo*, or corporation of the city. Mexico contains a population of about 140,000, of whom nearly one-half are whites, either European or Creole, the remainder Indians, Negroes, and the various mixed casts. There are in the streets, without habitation, and almost without food or work, nearly 30,000 Indians, called *Guachinangos*, who resemble the *Lazzaroni* of Naples, though, unlike them, they neither beg nor are tumultuous. As a small quantity of labour will enable them to indulge the propensity for drunkenness, they are often seen in the streets in a state of intoxicated insensibility, when they are carried to the guard-house, and, when recovered, set to work by the police. They are employed in cleansing the streets, and, in a day or two, having acquired sufficient to purchase as much pulque as will intoxicate them, they are soon again in the same condition, transferred to the guard-house, and from thence to the streets, and thus pass their lives in alternate drunkenness and punishment.

As Mexico is built on a marshy soil, water is to be found everywhere, by digging a few feet, but this water is not much approved by the inhabitants, except for washing. The principal supply is by means of aqueducts, which convey the water to the different parts of the city. The best is from the lake of *Xochimilco*, which is remarkably pure and limpid, and runs incessantly. Every kind of provision is cheaply and abundantly supplied from the surrounding districts, which are highly cultivated, and covered

with a hardy and numerous population, whose principal occupation is the labour of agriculture. The consumption of pulque within the city is enormous; a duty is collected at the gates which produces annually 600,000 dollars. The consumption of bread in Mexico is, in proportion to the population, nearly the same as in the cities of Europe. Beef is less eaten than mutton; the annual supply of oxen is only 16,000, whilst that of sheep is 273,000. Salt is made near the city. The clayey soil is impregnated with muriate of soda, which is dissolved, and, by evaporation, refined so as to fit it for culinary purposes. In regard to the supply of all necessaries, no city can be more favourably placed than Mexico, and its local position is such as to give it a commanding influence over the whole of the American continent. It can more easily communicate both with Europe and Asia than any other capital, and nothing is wanted to augment its importance to an astonishing extent, but a free commerce, more liberal institutions, and an intercourse with some port to the northward of Vera Cruz, in a more healthy climate than that city enjoys.

Mexico.

The next important place to Mexico in the intendency of that name is Queretaro, a city of 35,000 inhabitants, surrounded with mines, celebrated for its beautiful houses, its aqueducts, and some manufactories of cloth. Tezcuco contains 5000 inhabitants, who are principally employed in the manufacture of cotton goods. Chilpancingo depends on the cultivation of wheat on the fields that surround it. The number of its inhabitants is about 7000. Cuernavaca, on the southern declivity of the *Cordilleras*, is in a most delicious climate, and abounds in all the fruits of both climates, being only 3500 feet above the level of the sea. Cuyoacan, Tacuba, Tasco Lerma, Toluca, Pachuca, Cadereta, and St Juan del Rio, are the only other towns in the interior. Their population increases rapidly, and though some of them have mines in their vicinity, their principal dependence is on agriculture. The two towns on the coast of the Pacific Ocean are Acapulco and Zacatula. The inhabitants of the former amount to 4000 usually; but, when the ships from Manilla visit the harbour, the population is generally tripled. The granite mountains by which it is surrounded render it very sickly; though, by a large cut through them, which has created a current of air, it is rendered less noxious. Zacatula, though a good port, has but little trade; and, being to the northward, it enjoys a more healthy climate. The coast is very dangerous in the months of July and August, when tremendous hurricanes blow from the south-west; at that time, and even in September and October, the ports are difficult of access; and, even in the fine season, from October to May, impetuous winds from the north-east and north-north-east, known by the names of *papagallo* and *tehuantepec*, render the coast very hazardous. The south-west winds are attended with thunder and heavy rains, whilst the others are prevalent when the sky is clear; and what the English sailors call in the West Indies white squalls are excessively dangerous.

The intendency of Puebla contains 813,300 inhabitants, and extends over a surface of 2696 square leagues. Its frontage towards the Pacific Ocean is

Mexico. 26 leagues in length, between the intendancies of Oaxaca and Mexico; but it has neither harbour nor navigable river. The greater part of the intendancy is traversed by the Cordilleras. It extends through four degrees of latitude; and, though wholly in the torrid zone, from the great inequalities of its surface, possesses the productions and the climate of every part of the globe. The table-land, which is from 5900 to 6500 feet above the level of the sea, is eminently fruitful in wheat, maize, agave, and fruit trees. It still exhibits remarkable vestiges of the ancient Mexican civilization. The highest mountain in Mexico, Pococatepetl, is in this province. It is volcanic, but for the last three centuries has only discharged smoke and ashes. It is 2000 feet higher than the highest peak of the Alps, and, with one exception, is the highest mountain of North America. The population of this district is principally concentrated on a small part of it: and almost the whole track, from the central table-land to the shores of the South Sea, though well adapted for the cultivation of sugar, cotton, and other tropical productions, is nearly a desert. The most favourable production of the elevated plain is wheat; for a long period it made but slow progress; but, as the road towards Vera Cruz has advanced, the cultivation of this grain has increased; and probably at no distant period it will become the granary for the supply not only of Cuba, Porto Rico, and the Caraccas, but of the whole West India settlements. The most remarkable objects now left of the ancient Mexicans are the mounds or pyramids, one of the largest of which is to be found in this intendancy. Its sides are exactly in the direction of the parallels and the meridian. It is constructed of alternate layers of clay and bricks. Its height is only 177 feet, but its base is 1423 feet on each side. On the top of it is a church, on a platform of 45,200 square feet, in which mass is daily celebrated, by a priest of Indian extraction. This pyramid of Cholula was used, by the former inhabitants, as a temple, or rather altar, on which human victims were offered. It was in this intendancy that Cortez laid his plans for the subsequent subjugation of the whole country, and where he found those assistances without which he could have made no efforts with any prospect of success. It had been long possessed by the two powerful republics of Tlascala and Cholula, the former of an aristocratic, the latter of a democratic kind. The latter had been recently subdued, and was not reconciled to the government of Montezuma; the former still resisted, though against fearful inequality. Cortez released Cholula from its subjection, though by the exercise of gratuitous and sanguinary cruelty; and then, having made alliance with Tlascala, the population of both states were placed under his orders, and operated that great change which the empire of Anahuac experienced. The defection of Cholula, which was the centre of knowledge, and the arbiter of the customs and religion of the country, which was resorted to by pilgrims from all parts of it, and by that means diffused its feelings and ideas, was more injurious to Montezuma than the firm hostility which Tlascala maintained. When the power of both republics were united, under the orders of such a captain as Cortez, and

directed by the knowledge and valour of Europeans, it is not wonderful that the empire of Mexico perished.

A vegetable curiosity of most extraordinary kind is to be seen in Puebla: A cyprus tree, at the village of Atlisco, whose circumference is 76 feet 4 inches, and whose hollow trunk is 16 feet in diameter. It is unfortunate for the intendancy, that four-fifths of the land in it is in mortmain, or under Majorazgos. The greater part of it is the property of municipal, ecclesiastical, or charitable corporations, and cannot be alienated.

The principal city is Puebla de los Angeles, the most populous place of Spanish America, next to Mexico. It contains 70,000 inhabitants, by far the greater proportion of whom are Indians. The municipality, by ancient privilege, is wholly of the native race, no white man being eligible. It consists of a cacique and four alcaldes, under the control of an Indian governor, who is, however, under the command of a European intendant. Cholula, the next city, now contains about 16,000 inhabitants, mostly Spaniards, or the mixed casts, who are chiefly occupied in cultivation. Tlascala has fallen from its pristine state, and is now reduced to only 3500 inhabitants, not more than one-fourth of whom are of the original race. Thus, whilst Puebla de los Angeles, a town founded by Spaniards, is almost wholly occupied by Indians, this place, once the seat of the most numerous and warlike population of Mexico, has become deserted by the aborigines, and the white population predominates. Atlisco, Tehuacan, Tepeaca, and Huixtotezco, the other towns, are not populous, although the farms and mines in their vicinity maintain a considerable population.

The intendancy of Guanajuato is the smallest in New Spain; but the density of its population, and its mineral wealth, more than compensate for its deficiency in extent. It extends over a surface of 911 square leagues, and contains 517,300 inhabitants, giving 586 souls to the league, a relative population greater than many countries of Europe, and much greater than in any other part of the Spanish dominions in the western hemisphere. Its rapid increase may be dated to have commenced about fifty or sixty years ago, when the rich mines of Marfil, Santa Ana, Santa Rosa, Valenciana, Rayas, and Mellado, began to yield their immense wealth. The metallic produce of these mines far exceeds the celebrated hill of Potosi, in Peru, or any other district in either continent. The riches of the mines have induced cultivation where deserts before only existed, and cities and towns have risen with astonishing celerity. No part of New Spain exceeds this in the quantity of agricultural produce, though it is all situated at a considerable elevation. Wheat and maize are beneficially cultivated, and the supply of cattle and esculent vegetables is abundant. The principal city has the same name as the intendancy, but is sometimes called Santa Fé de Guanajuato. It is of ancient incorporation, but of recent growth, and now contains within the town 41,000 inhabitants, while 30,000 live in the mines and farms that immediately surround it. Some of the residences of the proprietors of the mines are of a degree of mag-

Mexico.

Intendancy
of Vallado-
lid.

nificence and taste, which would be deemed ornamental in the finest cities of Europe. The hall of the Cabildo, the churches, and convents, are beautiful, and give to this recent city an air of grandeur and prosperity. The city of Salamanca is finely situated on the banks of the river El Grande, which runs into the lake of Chapala. Celayo and Salvatierra are cities of no great extent, but rapidly increasing, as are the towns of San Miguel, San Felipe, and Leon; all of which are of modern foundation since the great influx of wealth from the mines.

The intendancy of Valladolid is 3446 square leagues in extent, and contains 376,500 inhabitants. It has a line of coast on the South Sea, about 38 leagues in length, but has no port or navigable river on the whole of its border. It is situated on the western declivity of the Cordilleras, intersected with hills and delightful valleys, which exhibit the unusual spectacle in the torrid zone of verdant and well watered meadows. In descending to the coast, the climate is hot and the soil arid. The most singular feature in this intendancy is the Volcano de Xorullo, or Juruyo, which was formed in the night of the 20th September 1759. The catastrophe in which this mountain rose in one night, to a great height, and totally changed the face of a great extent of country, is one of the most singular of which we have any recent and accurate accounts. Till the period of the combustion, the extent of ground between two brooks, called the San Pedro and the Cuitamba, was occupied by plantations of indigo and sugar canes. These two streams were bounded by basaltic mountains, the structure of which indicated that the district, at some remote period, had been subject to great volcanic convulsions. Fields, beautifully irrigated, formed the plantation of Xorullo, one of the richest and most prosperous in the whole province. In the month of June 1759, subterraneous rumbling noises were heard, and were attended with shocks of earthquakes, that, during an interval of fifty or sixty days, created terror in the cultivators. In the beginning of September, tranquillity appeared to be restored. The roaring had ceased, and the earthquakes were suspended. In the night between the 28th and 29th, the horrid rumbling recommenced, and with increased loudness, so as to terrify the inhabitants, who fled to the adjacent mountains. During the night, a surface of ground, from three to four leagues in extent, swelled up like an enormous bladder, in a convex form, whose elevation, in the centre, was 520 feet above the level of the ground from which it rose. Those who saw the awful spectacle assert that flames issued forth for an extent of more than half a square league; that fragments of burning rocks were thrown to prodigious heights; and that, through a cloud of thick ashes, when illuminated by the volcanic fire, the softened surface of the earth was seen to lift itself up like the waves of the sea. The two rivulets ran into the fiery chasm, and the decomposition of their waters contributed to invigorate the flames. Eruptions of mud, and especially strata of clay and basaltes, in concentric layers, indicated that subterraneous water had a great share in producing this extraordinary convulsion. Thousands of small cones, from six to ten feet

in height, were projected from the surface, which became a kind of funnel, from which a thick vapour ascends to the height of from forty to sixty feet. In many of them a subterraneous noise appeared to indicate the proximity of some fluid in a state of ebullition. In the midst of these cones, or, as they are named by the inhabitants, ovens (*hornitos*), six large masses were protruded to the height of from 1300 to 1650 feet above the old level of the plain; the most elevated of which now forms the volcano of Xorullo. It is constantly burning, and has thrown up from its north side an immense heap of scorified and basaltic lavas, containing fragments of primitive rocks. The great eruptions of the central volcano continued till February of the following year, when they began gradually to diminish. The country has ever since obtained the very appropriate name of *Malpays*. The terrified inhabitants, who had retired to a distance of between seven and eight leagues, became gradually reconciled to the spectacle, and having returned to their cottages, beheld, with admiration, the streams of fire issuing from a vast number of great and small apertures. Although the subterraneous noises now appear by no means violent, and the Malpays, and even the great volcano, begin to be covered with vegetables, yet the ambient air is so heated by the action of the small ovens, that the thermometer, in the shade, at a great distance from the surface, rose to 109. The traveller is still shown the two brooks, whose clear streams formerly watered the plantation, bursting forth at a distance of more than a mile from the spot where they were enveloped in the chasm created by the volcano. These streams, if the same, are now united in one, and are of the temperature of 126. There is near them a sulphurous stream, more than 22 feet in breadth, the water of which is most highly impregnated with that mineral. The belief among the more rude Indians in the vicinity is, that the convulsion was a miracle wrought by some Capuchin friars, who had preached, but without effect, to their tribes; that being thus rejected, they poured forth imprecations, and declared that the plantation should be first destroyed by earthquakes and volcanos; and that when the latter were burnt out, the climate would gradually cool, till, from being perpetually buried in fire and snow, it would become totally uninhabitable. As the first part of the prediction has been fulfilled, and as the gradual coolness has been increasing, they live under a strong impression that the latter will also be accomplished, thus expecting an impossibility, because a natural, though unusual, operation of nature has taken place. The industry of the monks, in making converts among the Indians, is very great; many of them are constantly employed in the work, and their anxiety to succeed in it is such, that they seldom fail to avail themselves of any natural occurrence that can be made subservient to their views.

The Indians, who inhabit this province, are of three different races, and each retains its original language;—the Tarasces, who were famed in the sixteenth century for their industry, and the advancement they had made in the mechanical arts; the Otomites, who are remarked for their low degree of civilization, and their peculiarly gut-

Mexico.

Mexico. tural language, which was noticed by Cortez at the first discovery; and the Chichimecs, who, like the Tlascalars, have preserved the ancient language spoken at the Aztec court. The whole of the north part of the intendancy is inhabited by these tribes, who preserve their ancient separation, if not their enmity. They are, however, all Christians, and the only white man seen in their villages is sometimes a priest, though even the ecclesiastics are more frequently of the Indian or Mestizo race. The benefices are so poor, that it is with difficulty any of the clergy can be induced to reside in a country where no Spanish is spoken, and which on the sea coast is so unhealthy, that the priests frequently die of malignant fevers within six or eight months after their induction. The population of this intendancy decreased very much in the year 1786 and 1790, when the country, from long drought, was visited by scarcity approaching to famine. The suffering of the inhabitants would have been much greater, but for the humanity of the bishop of the diocese; who, at a loss of more than 50,000 dollars to himself, procured maize from the neighbouring provinces to feed the poor.

The principal city, Valladolid de Mechoacan, contains about 18,000 inhabitants; it is the see of a bishop, and the residence of the intendant. The town-house, churches, and convents, are handsome, and the public walk, the *Alameda*, celebrated for its beauty. Pascuaro, the next city, is finely situated on the border of a lake of the same name. It contains 6000 inhabitants, mostly Indians. A former bishop of Valladolid is interred here, Vazco de Qui-rago, who was distinguished by his humanity to the Indians, and by the skill with which he inspired them with the practice of industry: he died in 1556, but his memory is preserved by the rude tribes, who still call him their father. The only town besides is Huitzitzilla, with 2,000 inhabitants. Some of the mines are very valuable, particularly those of Zita-quaro and Real del Oro.

Intendancy
of Guadala-
car.

Guadalaxara is an intendancy extending over a surface of 9612 square leagues, and maintaining a population of 630,500 souls. It stretches 123 leagues along the shores of the Pacific Ocean, where it has the single port of St Blas. It is crossed from east to west by the Santiago, a considerable river, which rises on the lake Chapala, and empties itself into the Pacific Ocean, near St Blas. It is a most important means of communication between the interior of the country and the sea, and though now only used for floating timber to the naval arsenal, is capable of being made the route for the productions of Salamanca, Guanajuato, and Zelaya, to the ocean. The volcano of Colima in this province rises to the height of 9200 feet above the sea; but the plain on which it stands being 5500, its appearance is not striking. No eruption of it is recorded, but it frequently throws up smoke and ashes. It is the most westerly of all the volcanos of New Spain. This intendancy is both an agricultural and manufacturing district: according to the statement made by the intendant, the value of its annual agricultural produce amounted to 2,599,000 dollars, and that of its manufactures to 3,302,000. Maize, wheat, and cotton, are the

principal productions of the soil, whilst the manufac-tories furnish cloth from cotton and from wool, both for the inhabitants of this district and some of the surrounding ones. One of the most productive mines of New Spain, that of Balanos, is within this intendancy, besides which are Asientos de Ibarra, Copala, Guichichila, and several smaller ones. The city of Guadalaxara is the residence of the bishop and of the intendant; and the highest court of justice, the Royal Audience, has its sessions in it. It is a corporation with a cabildo. The edifices are some of them very magnificent. The population in 1793, according to Humboldt, was 19,500; but by an account now before us taken in 1809, it appears to amount to more than 40,000. The only other city, St Blas, if it were not unhealthy, would at some time become a port of vast importance. It is the best harbour on the western shore of Mexico. It has an inland communication by means of the river St lago. The country about it is well covered with excellent ship timber. Pitch, tar, and turpentine, are to be procured with facility, and hemp and flax grow as far as they are permitted almost spontaneously. It is already the principal arsenal for building ships, and the chief place where the few ships of war, belonging to Spain, in those seas are refitted. It was in the contemplation of the government to concentrate their naval affairs by conveying the stores of St Blas to Acapulco, but the superior advantages of the former port has induced the continuance of it as an arsenal.

Mexico.

The intendancy of Zaccatecas contains 2350 square leagues, and a population of 153,000 inha-bitants. Its dependance is almost wholly on the rich mines which it contains. The table-land, which forms the centre of the district, is composed of sienite, on which strata of primitive schistus and schis-tous chlorites repose. The schist forms the base of the mountains of grauwacke and trappish porphyry. There are nine small lakes to the north of the capi-tal, which abound in muriate and carbonate of soda, especially the latter. This carbonate is of great use in dissolving the muriates and the sulphurets of sil-ver. The central table-land of Asia does not abound in soda more than this part of Mexico. Some of the richest silver mines are worked in this province, where was discovered the *vea negra de Sombrete*, the richest seam that was ever discovered in either hemisphere. Zaccatecas, the chief place, contains a population of 33,600 inhabitants. Sombrete and Fresnillo are large well-inhabited places, and in-creasing as the productiveness of the mines which they surround increases.

The intendancy of Oaxaca is one of the richest in New Spain; its extent is 4447 square leagues, and its inhabitants amount to 535,000. Its south-ern boundary extends along the coast of the Pacific Ocean from Guatemala to the province Puebla, a distance of 110 leagues. Oaxaca is one of the most delightful countries in this quarter of the globe. The beauty and salubrity of the climate, the fertility of the soil, and the variety and richness of its productions, all minister to the prosperity of the in-habitants, who have, in consequence, from the most remote period that we are acquainted with, been the

Mexico.

most advanced in civilization of any portion of New Spain. The mountain soil of this province forms a singular contrast with that of the adjoining districts. In place of the strata of basaltes, and amygdaloid, and porphyry, with grüstein base, which cover the other regions, only granite and gneiss are found in these mountains. The height of these granite summits are not ascertained, but the Cerro de Senpual-tepec is said to be the loftiest, and from one of its heights both the seas are to be seen. This intendancy comprehends two mountainous districts, called Mixteca and Tzapoteca. The Indians of the former, who principally cultivate the nopal for the cochineal insect, are an active, intelligent, and industrious race of people. Some ancient cemeteries which exist, though in ruins, show that the inhabitants of this district, before it was known to Europe, had made more progress than the other natives of this continent. The palace of Mitla was appropriated as a retirement for the sovereign, to lament for the loss of a wife, a mother, or a son. It forms three edifices, the principal of which is best preserved, and is 130 feet in length. A staircase formed in a pit leads to a subterraneous apartment, 88 feet by 26. This gloomy place is covered with *treceques*, the same as the exterior walls of the palace. The most material distinction between this and other Mexican edifices is, its having pillars of porphyry to support the ceiling; they are 17 feet high, and the shaft is a single piece. The similarity of the apartments to those found in Upper Egypt is very striking. This province gives the title of marquis to the family of Cortez, and the majorazgo belonging to them consists of four towns and forty-nine villages, which contain 17,000 inhabitants. The principal city, Oaxaca, but sometimes called Antequera, contains about 24,000 inhabitants. It is the residence of the bishop, of the intendant, and the court of justice. It is well built, and was, till the late disturbances, when the insurgents entered and plundered it, a most rapidly improving place. San Antonia de los Cues is a populous place, and carries on a considerable trade. The only port is Teguantepec, at the mouth of a river, whose bar impedes the entrance of large vessels. It is, however, the channel by which the indigo and other valuable products of Guatimala pass into the river Huascualco, in their way to the European markets. The most considerable mines are Villalta, Zolga, Yxtepexi, and Totomosla, but their produce is inconsiderable, when compared with the richer veins to the northward.

Intendancy of Merida.

Merida is an intendancy of New Spain, though it comprises only the peninsula of Yucatan, which formed no part of the ancient empire of Mexico, and is now in part inhabited by a few straggling British subjects, and a numerous body of unclaimed Indians. Its extent is 5977 square leagues, and its population is estimated at 465,000, the far greater part of whom live an errant life. Cape Catoche was once probably joined to Cape Antonio, in the Island of Cuba; but the period when the impetuous force of the ocean burst the barrier, and formed the Gulf of Mexico, must be more a matter of conjecture than either of history or of calculation. The

Mexico.

peninsula has a ridge of high mountains in the centre, which divides the part to which the English have access from the Spanish inhabitants. The western side of this range alone is, strictly speaking, under the Viceroy of Mexico, who has issued orders for the Indians under the authority of Spain to be removed to such a distance as shall prevent their assisting in contraband trade. The soil of this peninsula, when cultivated, is fertile, and yields the subsistence and subjects of commerce which a tropical climate usually affords. Its hills abound with cattle, whose hides and tallow constitute part of the exports. The climate, especially in the hills in the centre, is salubrious, and refreshed by the sea breezes. Campeche is the principal place of commerce, but the whole shore is so flat, that vessels cannot approach within six or seven miles with safety. Its inhabitants are estimated at 7000 or 8000. The town of Merida is on an arid plain, forty miles from the coast. A small river passes it, and enters the sea at a part which can scarcely admit the entrance of large boats; what little commerce it enjoys is by this channel. Its exports consist principally of honey, wax, and an inferior kind of cotton; but the latter article, owing to the want of machines for clearing the seed from the wool, is of very little value. The population of the town is 10,000 souls. Besides these, there is the small town of Valladolid, with about 2500 inhabitants. The rest of the population is scattered in small villages, or spread in wandering tribes. The wood, which takes its name from one of the towns of this province (*Campeche*), is found in great abundance. It is suffered to dry for one year after it is cut down, when it is usually carried to Vera Cruz or Havana, to be conveyed to Europe. The expences of its conveyance are so great, in proportion to its value, that it is scarcely worth converting into an article of commerce. There are no mines of any description in this intendancy.

The intendancy of Vera Cruz is a narrow strip of land extending along the coast of the Gulf of Mexico, from the river Baraderas or de los Lagatos, to the great river, or rather the estuary of Panuco. Its length is 210 leagues, whilst its breadth is only from 25 to 28 leagues. Its whole surface is an extent of 1140 square leagues, and its population no more than 156,000. Having already, under the division of commerce, taken a view of its most important depot, the city of Vera Cruz, the capital of this intendancy, we pass on to the description of its interior. There is no region of even the new continent where the change and variety of climate and production is so abrupt as in this province. The high and snowy mountains approach almost to the shore, where the intense heat of a vertical sun is felt with the fullest fervour. The western side of this district forms the acclivity of the table-land of Mexico, and the ascent is so sudden, that, in the short space of a single day, the traveller from the plain above may, from the regions of eternal frost and snow, reach the level ground on the shore of the ocean, where the most suffocating heats prevail. In ascending to the upper plain, the increase of elevation is distinctly marked by the different trees, and other vegetables, and by the modes of cultivation which the peasantry pur-

sue. The growth of the oak points out the limit which nature has assigned to the dreadful fever of the low country. When the region where that tree grows is once gained, the apprehension of infection from the contagious disease of the warm climate may be at rest. In ascending to Xalapa, 4300 feet, the forests of liquid-amber announce that the traveller is in the region where the clouds from the ocean come in contact with the humilitic summits of the Cordilleras. A little higher, the banana tree, whose fruit induces indolence in the native of the hot climates, ceases to be productive, and thus compels the peasant to a more laborious kind of cultivation. At the height of San Miguel, pine trees begin to mingle among the oaks, and gradually increase to Perote, at the elevation of 7700 feet, where the eye of the traveller is first regaled by the spectacle of extensive fields of wheat. A thousand feet higher the climate forbids the growth of the oak, and only pines are to be seen, which clothe the mountains till they penetrate the region of perpetual snow. The coast of Vera Cruz is very thinly inhabited; this may in some measure be owing to the insalubrity of its climate, though no more can be owing to that cause there, than in the other tropical regions; but as the coast is the frontier against a naval enemy, the only one that New Spain could dread, the military service in the middle demanded from the inhabitants was much greater than in the cooler regions, and the climate was much less oppressive, and the country was much less fertile, than in the coast to escape the cold season, and the want of land, and cavalry. Though there is a hot spot on the globe, yet even there the exposure has been exposed to a want of provision, and the scarcity of labourers in its vicinity, and the small portion of work which its production demands.

In this province two mountains of great height. The volcano of Orizaba is 17,300 feet above the level of the sea; it resembles a truncated cone, and a crater, which incline towards the south-east, is visible at a prodigious distance. Its upper part is always covered with snow. Smoke constantly ascends from it, but it has not terrified the inhabitants by an eruption within any known period. The Collier of Perote, another mountain, and which, with Orixaba, serves as a guide to mariners in approaching the coast, is 13,500 in height. On its summit is a square mass, resembling a large chest, from which its name has been obtained. No crater is to be seen upon it, nor are any eruptions recorded, but currents of lava, near some villages in its vicinity, appear to indicate that at some distant period there must have been a lateral explosion. A volcano at Tuxtla, to the southward of Vera Cruz, has had frequent eruptions within recent periods; one, in March 1793, was very considerable, the houses in Vera Cruz, Oaxaca, and Perote, were covered with ashes, and at the latter place, though a distance of 180 miles, the subterraneous noises which were heard there at the same time resembled heavy discharges of artillery. There are no mines at present worked in this intendancy; some were formerly explored, but, after being ascertained to be too poor to be profitable, they have been abandoned. Some medicinal productions, of more value to

the physician than to the merchant, are collected in this intendancy. The root of the *Convolvulus jalapae* is found near the city, from which it has received its name. Sarsaparilla is also found in plenty in the humid and shady ravines of the Cordilleras. The royal monopoly of tobacco is supplied with part of its consumption from the vicinity of Cordova, and creates a large portion of that productive branch of revenue. The city of Vera Cruz is the capital of the intendancy, and to what has been already noticed concerning it, it will be sufficient to add that its population is 16,000 inhabitants, and that the public buildings and houses are all built of materials drawn from the bottom of the ocean; a species of madrepones and petchistein, as there is neither stone nor clay in the neighbourhood. Water is very scarce and brackish, so that most houses are provided with tanks for holding the rain, which falls in most copious showers, or rather torrents, at some seasons.

Xalapa, or Jalapa, is a city rather more than half the height of the central table-land. The climate being good, it is the resort of the richer inhabitants of Vera Cruz, when their commercial affairs do not demand their personal attendance. The sky is serene and beautiful in summer, but from December to February it wears a most melancholy aspect. When the north winds blow at Vera Cruz, the inhabitants of Xalapa are enveloped in a thick fog, the thermometer falls to 60 or 61, and for several weeks the sun and stars are utterly invisible. In the other parts of the year, when the heats on the coast are intolerable, and the sufferings from insects highly annoying, the residents at Xalapa enjoy all the delights that the most voluptuous climate can afford. The buildings in this place are spacious, and partake of that character of magnificence which is prevalent in New Spain. Some attention to study and to the fine arts is paid; and there is a School of Drawing, in which children of the poorer artisans are instructed, at the expense of the richer inhabitants. The population amounts to about 11,000, the greater part of whom are whites.

Perote is a fortress rather than a town, and in it the treasure destined for Europe is usually lodged, to wait a secure means of conveyance. In time of war, it is said to have contained at one time more than 10,000,000 of dollars, waiting an opportunity of being conveyed to Cadiz. It is nearly 8000 feet above the level of the sea, and in a country peculiarly barren.

Cordova is a large town, in a good climate on the eastern declivity of the Pic de Orizaba, whose inhabitants about 6000 are mostly employed in the cultivation of tobacco; as are those of Orizaba, another town of nearly the same population, a little to the eastward of Cordova. The inhabitants of these two places had a contest of many years continuance, respecting the course of the new road from Vera Cruz to Mexico. After much intrigue, many law-suits, and much bribery, a road was begun, and is now proceeding from Perote to Xalapa, and from thence to the bottom of the mountains near Vera Cruz, which, when completed, will have a powerful effect on the future condition of the whole viceroyalty. There are many smaller towns on the more elevated

Mexico. parts of the province, which is indeed by far the best peopled division of it; but in the border on the sea-coast there are merely plantations, *haciendas* or grazing tracts, *ranchos*, with none but the necessary labourers which the two species of establishments require.

Intendancy
of San Luis
Potosi.

San Luis Potosi is the largest intendancy in New Spain, and, like the other northern parts of the viceroyalty, very thinly peopled. Its extent is 27,260 square leagues, and its population 335,000. Though this extent is mentioned, it is by no means to be relied upon, for the limits to the north have never been ascertained with any tolerable accuracy, and the greater part has never been explored by any but the native Indians. A considerable district lying between the rivers *Conchos* and *Bravo del Norte*, called *Bolson de Mapimi*, extending over 3000 leagues, is occupied by tribes of Indians called *Apaches*, who make perpetual incursions on the Spanish settlers in Coahuila and New Biscay. San Luis Potosi, from its southern extremity to the ridge of mountains which separate it from the *provincias internas* (which will be presently noticed), presents a regular declivity; beginning at the table-land of Mexico, and with a gentle descent terminating near Saltillo, where the only opening in that range of mountains is to be found. The southern part is a country whose mines are very productive, and in the northern they are supposed to be equally rich, but the want of capital and the thinness of the population have hitherto prevented them from being explored. The southern part is fertile and cool, with the exception of some of the deepest valleys and the highest mountains. Wheat is grown sufficient for the higher class of inhabitants, but the poorer classes use bread made from maize. The whole country is well supplied with animal food, either from itself or from the *provincias internas*. As there are no settlements between the river Sabina and the mountains which divide it from Texas, this province contains 1500 square leagues without habitations, and most parts of the district present nothing but impassable marshes. Mr Latond, a French engineer who passed through this country, states, that eight leagues north of Chichi there are hills which abound in coal, from which subterranean noises resembling discharges of artillery are frequently heard. It occupies ten or twelve weeks to travel from the city of Mexico to the frontiers of this intendancy, and the greater number of nights, from want of habitations, must be passed in the open air. The city of San Luis, the capital, contains a population of 12,000 inhabitants; being the seat of the board of revenue for the *provincias internas*, it has considerable intercourse with them. The mines of Catorce have only been worked since 1778, but they now hold the second or third rank among those of New Spain. These mines are in rocks easily worked, and requiring but a small supply of gunpowder to blast them. They have, too, the great advantage of being free from water almost altogether, so as to need no costly machines to discharge it. The town of Catorce, situated near the mines, and depending on them, has risen with great rapidity from an obscure Indian village, to be a large and flourishing place, and though not yet dignified with the title of city, it

is much larger than many other places so incorporated.

Though the intendancy of San Luis Potosi extends over the four provinces of Leon, Santander, Coahuila, and Texas, those divisions are no part of the viceroyalty of New Spain, but are under a chief independent of its control, though, in affairs of revenue, they are accountable to the intendant of St Luis, and in law processes their last appeal is to the court of royal audience in the city of Mexico. As these provinces are but little known to Europe, were but slightly noticed by Humboldt, and yet promise at no distant period, both from their natural properties, and from their local situation, as the frontier towards the United States, to be subjects of considerable interest, we shall describe them according to the *Memorial* which their delegate to the Cortez at Cadiz, Don Miguel Ramos de Arispe, presented to that body.

These four provinces occupy two hundred and twenty leagues of shore on the Gulf of Mexico. Though none of the ports are good, and all have bars at their mouths, yet they are capable of considerable improvement, and probably would be improved, if greater freedom of commerce were allowed them. The harbour at the mouth of Rio Bravo del Norte, called *El Braza de Santiago*, is the best on the coast. It has never less than thirteen feet water at its entrance, and as the tide sometimes rises three feet, it would admit vessels, properly adapted for it, of 400 tons. It is defended from the prevailing storms by the island Malahuitas. The river is already navigable forty leagues upwards, and might be made so, with very little exertion, thirty leagues higher. The port of San Barnardo, in lat. 27° 30', was, indeed, in 1808, decreed to be opened for admitting vessels either from Spain or the colonies, but up to March 1812, only three small sloops had entered it, and owing to some jealousies of the officers of government, the restrictions on commerce were such as to forbid the hopes of increase. *El Soto de la Marina*, a port now closed by authority, in 24° 29' of north latitude, if it could be opened, would be improved by its own inhabitants, who are anxious to be allowed to do so. These four extensive provinces are separated from the other dominions of Spain by ridges of mountains which are impassable in most parts by horses, and totally so by wheel carriages, except at the single chasm where the city of Saltillo is built, and which has, in consequence, become the focus of all communication. Their intercourse with each other is maintained with great facility, both by means of their rivers and their extensive and rich plains; and they can exchange their different productions without encountering those difficulties which almost exclude communication with New Spain. Coahuila, the largest of the provinces, is the southernmost, and divided from San Luis Potosi and Zacatecas by the Cordilleras before noticed. It is 200 leagues in length, and 100 in breadth. Its situation is generally elevated, and being well sheltered from the north-west winds, its climate is generally healthy, not too hot even in the summer, nor severely cold in the winter months. Its surface is most luxuriantly irrigated by the numberless springs which burst from its hills, and

Mexico. produce rivulets that contribute to increase the waters of the great river Bravo del Norte. The water of these springs is generally pure, from mineral solutions, and is pleasing to the taste, but some are impregnated with sulphur, and are used for medicinal purposes. Its pastures are clothed with rich natural grasses, and admirably calculated for breeding, rearing, and fattening cattle; and its forests furnish abundance of wood, well calculated for every kind of construction. There are mines of saltpetre, copras, alum, lead, tin, and copper, besides some silver in Santa Rosa, and gold in Sacramento. These mineral treasures, for want of population and capital, have been rather ascertained than explored. The inhabitants are almost wholly of the white race, or with such slight mixture of the Indian blood, as to make no distinction in colour worthy of notice. The native tribes within the province have been extinguished; but, on the borders, they have the warlike nations of the Lipanes and Cumanches to the north, and the Apaches and Mesqueros to the west. The principal town, Saltillo, contains 6000 inhabitants; it is the seat of the fiscal branch of the government for the four provinces. An annual fair is held at it, to which great crowds resort, and exchange their produce for the few articles of European luxury, which their high prices and the poverty of the inhabitants enable them to obtain. Monclova is deemed the capital of the province, because it is the head-quarters of the military; but the governor-general resides at Chihualhua, in New Biscay. He is independent of the viceroy of Mexico, and has equal power throughout the four provinces, except in matters of finance, and in legal decisions. Cohauila contained betwixt 70,000 and 80,000 inhabitants in 1811. They are solely occupied in agriculture, and produce excellent wheat and barley, and great variety of fruits. The vines cultivated here make wine of very excellent flavour, and considerable strength, and, if admitted into New Spain, would be a valuable source of riches. The province of Texas began to be peopled from Cohauila, in the middle of the last century. San Antonio de Bejar, the principal place, is called a city, as are Espirito Santo and Nacodoches; but all have a very small population. In each town, a troop of cavalry is established; and, since 1806, detachments have been posted on the rivers Guadalupe and Trinidad, and in the port of Arcotaisas. On account of the pretensions of the government of the United States, a body of militia of 700 men has been kept constantly in active service in this province, and they, with their families, have contributed to extend cultivation and to increase the population. The plains in this province are cultivated with indigo, coffee, and sugar, but to very trifling extent; and they produce zasafras, snake-root, and some other drugs. Mines are said to exist, but none are worked.

The province of Leon, or, as it is pompously designated by the Spaniards, the New Kingdom of Leon, is one hundred leagues in length, and fifty in breadth, all in a low and hot climate, except the town of Rio Blanco, and the Valley de Labradores, which are beyond the mountains, and with difficulty approached from the other parts of the province. Its

soil is generally fruitful, and abounds in excellent pastures, on which numerous cattle are bred. It produces abundance of corn and fruits; and mines of lead, tin, and copper, are slightly worked. The inhabitants affirm, that it has several rich mines of silver and gold, but they are too poor to work them. The city of Monte del Rey is the capital; it is the residence of the bishop, who has spiritual authority over the four provinces. There is in it a college, a cathedral served by seventeen priests, an hospital, and a convent of Franciscans. The capital contains 9000 souls. There is another city, Linares, and several towns, but they cannot be large, as the whole population of the province only amounted to between 70,000 and 80,000 inhabitants.

The province of Santander, like that of Leon, only began to be peopled about fifty years ago. As part of this province is on the coast, it is warm, but in general healthy, the air being free from humidity, and cooled by the trade wind in the day, and the land wind at night. The more elevated parts are cooler, but the mountains are not of that immense height, as to be intolerable even on their summits. The country is well irrigated, and the soil well calculated for every production of all climates. Its mines of tin, lead, and copper, are affirmed to be rich, and the ore of the latter is said to be the nearest to the pure metal of any hitherto discovered. The inhabitants amount only to between 60,000 and 70,000: Horcasitas, the capital, contains about 5000; the remainder are distributed in several smaller towns, and in numerous villages and farms, and are wholly employed in the affairs of agriculture. This province abounds with excellent horses, with which part of Mexico is supplied; they are of an active make, accustomed to perform long journeys, and, what is of vast consequence, when the use of shoes is not introduced, with very hard hoofs. The sheep have multiplied in an extraordinary degree, for the short period during which these provinces have been settled. They not only suffice for their own consumption, but supply the markets of Zacatecas, Queretara, Mexico, and Puebla, notwithstanding their immense distance. Notwithstanding the riches of the soil, and the salubrity of the air, the inhabitants of these provinces have made no progress to be compared with that of those who have proceeded from the United States, into the western part of the Continent, or to the British province of Upper Canada. This may be accounted for in some measure from the want of capital in the settlers; for it appears that they are obliged to sell their cotton, as well as the wool from their sheep, to the people of the south, as soon as it is collected, from not having money to pay for weaving it at home. Some manufactories have commenced at Saltillo, where about forty looms are at work; but such is their poverty, that they are obliged to sell every week what they produce, that they may purchase a supply of wool to work with in the subsequent week. Although this want of capital is a great impediment, it might be, and would be surmounted, if the bad policy of the government did not tend to keep them from improvement. Being prevented, by the system adopted in many parts of the Spanish dominions, from having direct intercourse

Mexico.

Mexico.

from their own ports with any other, all they want comes loaded with heavy duties and charges, and what they have to dispose of comes to the consumer with similar additions. In these kind of transactions the tax called *Alcavala*,—a duty on the sale of every commodity, is felt with peculiar pressure. This is strongly stated by Don Miguel Ramos in his *Memo-rial*.

"There is no open port for all the opulent kingdom of Mexico," he says, "but that of Vera Cruz, which has a most scandalous monopoly of all European goods. These goods at Cadiz are the second hand, Vera Cruz is the third, Mexico, Queretara, or Zacatecas, the fourth, the great fair of Saltillo is the fifth, thence they are spread every year to the dealers of the interior, which makes the sixth hand, and then to the consumer the seventh. These goods have to their original cost added the duties of export at the place from whence they are first sent; of importation and of exportation at Cadiz, of various duties at Vera Cruz, of the *Alcavala* there, the same at Mexico, at Saltillo, and the other dealers through whose hands they pass. To this must be added the expence of freights and carriage, and the profit of each dealer through whom it has reached the poor consumer. The *Alcavala* is even levied on the last purchaser, and with such tyranny and cruelty, that the poor labourer is compelled to pay it on the emnants of cloth he buys at Saltillo to cover his naked family; and the small quantities of rice, flour, or beans, which he sells there must bear the same costly expences of freights, profits, and *Alcavalas*. Whilst the merchants of Cadiz, of Vera Cruz, of Mexico, and of Saltillo, gain, the heavy weight of the duties and charges falls upon and impoverishes the poor cultivator, in the *provincias internas*."

It seems to have been the weak policy of Spain to make government precede, and not follow, population; to appoint officers of revenue before there are inhabitants to pay it; to build churches, and remunerate the clergy, before any worshippers are collected; and to appoint military commanders before any troops can be mustered. The policy, both of Great Britain and the United States, has been directly the reverse. As their subjects have proceeded to cultivate the deserts, they have been left to themselves; and when, by their increase in numbers and in wealth, which, on good soils, has been with great rapidity, they have felt the want of government, laws, religious institutions, or armed protectors, they have either been supplied to them, or their necessities have compelled them to provide those requisites from their own resources. In one case, nature has been left to her own course, and she has converted the desert woods into cultivated fields and populous cities; in the other, art has been exercised where it was unnecessary, and the consequence has been a slow, languid, and doubtful progress, accompanied with arduous struggles for even the necessities of existence.

Intendancy
of Durango.

The intendancy of Durango, or, as it is more usually called, of New Biscay, has an extent of 16,873 square leagues, and a population of 160,000 inhabitants. The northern border of this province, for more than 200 leagues, is inhabited by warlike and

Mexico.

independent Indians. The Acoclames, the Cocoyames, the Apaches, the Mescaleros, and Fardones, possess the Bolson and mountains of Chamante, on the left bank of the Rio del Norte. The Membrenos are farther to the west, in the wild ravines of the Sierra de Acha. The Cumanches, and the numerous tribes of Chechimecs, included by the Spaniards in the general and vague term of Mecos, disturb the inhabitants of New Biscay, and compel them always to travel in large bodies, or well armed. The military posts (*presidios*) on the frontiers, are too far from each other to intercept the excursions of these savage tribes, who are well skilled in all the stratagems of petty predatory warfare. The Cumanches are the mortal enemies of the Apaches, some of whose tribes live in peace among the Spaniards, and are formidable foes to the colonists of New Biscay. They have learnt to tame the horses, which have increased to wildness since the Europeans have settled in the country, and they are become expert and agile horsemen. The Cumanches, like all the savages who range extensive savannas, are ignorant of their original country. They wander over the plain accompanied by large dogs, whom they have trained to carry their tents, made of the hides of the buffalo. These savages are most to be dreaded on account of their cruelty, as they murder all their adult prisoners, and carry away the children, whom they preserve for their slaves. The Indian tribes on this frontier are certainly on the decrease; and, within the last twenty years, their inroads have been fewer. Their hatred to the whites is, however, unabated; and though the frequent want of success may have lessened their hopes, it has not diminished either their animosity or their courage. They have concentrated themselves in the vicinity of Moqui, and in the mountains of Nabajoa, and have driven away the Spanish colonists. The evil effect of being thus stationary in a strong country will be long felt, and prevent their becoming more civilized; as the spirit of revenge which Indians peculiarly imbibe will act as an obstacle to their intercourse with the Europeans, or with those tribes that live among them. If the same races of Mexican Indians existed in New Biscay as in the table-land of the viceroyalty, the wild tribes would be more likely to become gradually conciliated by them than by Europeans alone. But, in New Biscay, there are no Indians who pay the tax, and are thereby freed from the *alcavala*. All are whites, or so nearly approaching to that race, that they are accounted such.

This perpetual state of warfare with the Indians, which has long endured, by which the colonist, in his lonely farm, is under the necessity of being always watchful and always armed, has given to the inhabitants of the frontiers a degree of courageous energy, and a temperament of a peculiar kind. The climate is favourable to corporeal strength, and these causes have created a race of borderers who endure hunger, suffer fatigue, maintain watchfulness, and exhibit courage, which, though now only called forth by predatory warfare, would become powerful means of defence if they should be involved in warfare with the descendants of other Europeans, advancing towards them from the United States. This strength

Mexico. of body is said, also, to be productive of strength of mind, and a happy disposition of the intellectual faculties. Those who superintend the seminaries of Mexico have remarked that their most distinguished students in the exact sciences have been natives of the most northern provinces of New Spain. Durango is a mining country, and consequently furnishes both capital and consumers to the agriculture, which, for the paucity of the inhabitants, is in a flourishing state. Near the better-peopled division of the country, wheat is grown sufficient for those who prefer it to maize, which is, however, the common food of the greater proportion of the inhabitants.

The climate is generally temperate. In even the more settled parts, snow is not unusual in the winter, and the thermometer descends frequently below the freezing point to 14° of Fahrenheit. A singular group of rocks is seen near the capital, which have engaged the attention of mineralogists. The basis of these rocks, called La Brena, appear to be basaltic amygdaloid, which seem to have been raised up by volcanic fires. They are covered with scoria. They are in the midst of a level plain; are twelve leagues in length from north to south, and six leagues in breadth from east to west. They are of a most grotesque form; and, on the summit, there is a crater 320 feet in circumference, and 100 feet in depth. Near these rocks, a remarkably large mass of iron is found in the midst of a level plain; it is probably an aerolite. Its weight, calculated by its size, is 17 tons 9 cwt. The city of Durango is the residence of an intendant, and of the bishop of the diocese; its population amounted to about 12,000. Chichuahua, San Jose del Parral, and San Juan del Rio, contain about 10,000 each; and there are several smaller towns, many of which derive their names, as well as their existence, from the mines near which they have been built.

Intendancy
of Sonora.

The last intendancy of New Spain is Sonora, extending over 19,143 square leagues, and inhabited by 121,400 persons. From the proportion between its extent and population, it will naturally be inferred, that a very small portion only of it is cultivated. It extends through ten degrees of latitude on the Pacific Ocean and the Gulf of California. In some parts it is not more than 50 leagues in breadth, and in others 120. The post from Mexico to California passes through this district on horseback, and crosses the gulf in a launch to Loreto, or Old California. The whole distance traversed by the courier with correspondence from Guatimula to San Francisco, in New California, is upwards of 3000 miles. The northern part of Sonora is chiefly inhabited by a numerous Indian nation, called the Pimas. They mostly live under the direction of missionary monks, and are followers of the Catholic rites and ceremonies. In the ravines of this mountainous country much gold has been found, sometimes in very large grains; but the washing places are subject to incursions from some unreclaimed Indians, which prevent their yielding to the extent they would do under other circumstances. There has been hitherto no permanent intercourse between Sonora, New Mexico, and New California. The government has directed chains of missions to be established to preserve the communi-

cation, but its efforts have been fruitless. Two monks of the propaganda of Queretaro have recently been enabled to traverse the whole country from Monterey to San Francisco, without crossing, as is commonly done, into any part of California. Father Garces and Father Font departed from Horcasillas, and in eleven days reached an extensive and beautiful plain, at one league distant from the southern bank of Rio Gila, where they discovered the Casa Grande; the place at which the Astec nation rested many years, in its progress from the north to the place where it finally settled. It is constructed of rammed clay in squares of unequal sizes, but symmetrically placed. It is a square, each of whose sides is 445 feet and parallel to the cardinal points. The walls are four feet in thickness. The edifice had three stories and a terrace, and the staircase was on the outside. A wall, on which were square towers, surrounded it, and appeared to have served for purposes of defence. There are vestiges of an artificial canal from the river for supplying it with water, and the whole surrounding place is covered with fragments of earthen pots and pitchers, some of which are neatly painted with red or blue. There are besides found many pieces of the volcanic glass, or obsidian, which was used when the Spaniards first visited Mexico for mirrors, as well as for razors, knives, and arms. This is deemed by the Mexican antiquaries to be a decisive proof, that those who emigrated to this place came from some more northern region, where the volcanic production is profusely to be found. Those Indians who inhabit the plains near the river Gila, by no means deserve the appellation of savages, though they never had, before these missionaries visited them, any communication with the inhabitants of Sonora. They were found in villages of two or three thousand persons, were comfortably clothed, and had fields cultivated with maize, cotton, and gourds. The missionaries, in order to convert them, exhibited a large picture, painted on a cotton cloth, which represented a sinner burning in the flames of hell. It terrified them, and they requested the fathers not to unroll it again, or to speak to them of what would happen after death. These Indians are of a mild and sincere character. When the missionaries explained to them, by an interpreter, the security which prevailed in the Christian missions, where an Alcalde administered justice; the chief replied, "This order of things may be necessary for you, but we do not steal, and we very seldom disagree; what use then have we for an Alcalde among us?" The most considerable places in this intendancy are Sonora, the residence of the bishop, and Arispe, each of which contains a population of 7000 or 8000; but Cinaloa, Culiacan, and Las Almas, each reckon their inhabitants at near 10,000. There are several silver mines, which, though beneficial to their proprietors, are worked to a very limited extent.

New Mexico has been pompously dignified by New Spanish writers with the title of a kingdom, though it does not contain more than 40,000 souls, on a few detached spots in a surface of near 6000 square leagues. It is a long and comparatively narrow strip of country, through which that great river Bravo del

Mexico.

Mexico. Norte runs. Its boundary towards the north has never been ascertained, though the government of the mother country has claimed, as a portion of the whole track, up to the 38th degree of north latitude. In this view of it, the length is 175 leagues, whilst its breadth varies from 30 to 50 leagues. Though it has been settled, as far as establishing some towns can be said to settle a country, for more than 200 years, yet it is separated by uninhabited and most malignant marshes, in which travellers are frequently exposed to attacks from ferocious tribes of unclaimed Indians. Three stations were originally fixed on as garrisons (*presidios*) to maintain the communication; but in a general revolt of the Indians, they were either destroyed or abandoned. There are several passes which are dangerous for passengers, especially the defile of Robledo, to the west of the great river, and the desert del Muerto, in both of which, many white persons have been massacred by the wandering Indians. The desert of the Muerto is a plain of 30 leagues in extent, and destitute of water, and the whole of that district suffers from the same cause, as there is not a single spring issuing from the mountains of *Los Mansos*. From this aridity alone, it is impossible that the two populations should ever unite, how much soever they may both increase their numbers. Though New Mexico is in the same latitude as Syria and Persia, the climate is remarkably cold. It sometimes freezes in the month of May, and a little to the north of Santa Fé, the great river is frozen, sufficiently hard to admit the passage of men and horses in the winter season. The mountains which bound this great river do not wholly lose their snow till the beginning of June. The elevation of the river in these cold regions has never been exactly ascertained; but, at the capital, it is not supposed to be greater than 2200 or 2600 feet. The most interesting circumstance attending New Mexico is the great river Bravo de Norte, the Mississippi of this part of North America, passing through the whole of it; a circumstance which, when the country is fully peopled, must make its possession a matter of the highest importance. This great stream has its origin in the Sierra Verde; the point of separation between those streams that run to the south sea, and those that run to the Mexican gulf. Like the Orinoco, the Mississippi, and other American rivers of similar long course, it has periodical rises and falls. The waters begin to swell in April, increase through May, and reach their highest pitch in June. In the drought of summer alone it is fordable, and then, from its rapidity, only by horses of extraordinary strength. The borders of it are well wooded, irregular, and highly picturesque. Its waters are remarkably turbid, like the Orinoco and the other vast rivers of South America. The recollection of a very extraordinary event, which occurred in this river in 1752, is preserved by the inhabitants. The whole bed of the river became suddenly dry for more than thirty leagues above and twenty leagues below El Passo. The water made for itself a new channel near the Poridco of San Elcazarío. This loss of the river continued several weeks. The fine plains which surround El Passo, and which are irrigated by small canals, became wholly dry,

and the inhabitants could only obtain water by digging wells in the forsaken channel of the river. After a time the stream resumed its former course, and continued its accustomed channels, probably because in the new course the deposit of its mud had filled the chasm, and the subterraneous conductors had become filled up. In some part of the northernmost division of New Mexico, the rivers empty themselves into the Mississippi, and the river De Pecos is probably the same with the Red River of the Natchitoches; and, perhaps, when the geography of the district is ascertained, the river called by the Spaniards Napestia, may prove to be the same as that which lower down is called by the Anglo-Americans the Arkansas.

The colonists of New Mexico live in a state of perpetual hostility with the Indians that surround them; hence, though there are several towns and garrisons (*presidios*), there are no solitary farms or extensive plantations; all are concentrated around those places whose population is sufficient to bid defiance to the wandering Indians. The colonists are provided with all that nature absolutely requires from their own soil; the grains of Europe flourish, and the pastures supply abundance of animal food; all other supplies they must dispense with, as they are too far removed from the civilized world to maintain any commercial intercourse.

The capital is Santa Fé, situate to the east of the great river; its population is about 3600. Albuquerque, to the west of the Sierra Obscura, has a population of 6000, and Taos, to the north, has about 9000. The Passo del Norte is a garrison at which travellers must provide themselves with food to subsist on during their journey of 60 leagues over the desert which separates it from Santa Fé. The fields there are well cultivated with maize and wheat, and the vineyards produce excellent sweet wines. The gardens are well stocked with figs, peaches, apples, pears, and the other fruits of Europe. Artificial irrigation is here conducted on very simple but very good principles, and the effect is visible in all their crops.

Although the country of California is not, strictly speaking, a part of Mexico, yet it is a dependent upon the government of that viceroyalty, and can have no intercourse with Europe but through it; there seems, therefore, no place so proper to introduce the most recent information respecting it as after that country. It is divided into two intendancies, called New and Old California; the latter, though first settled, contains the fewest inhabitants; they are not estimated at more than 7000 or 8000, though the district contains nearly as many square leagues of surface. Of these, two-thirds are Indians, who, though they may be taught a few Catholic prayers and ceremonies, are almost as untamed as they were three centuries ago. The number of white people do not exceed 1000, who are dispersed on several missions and garrisons, designated on the Spanish maps with the names of towns, but which are in reality but miserable collections of hovels. Lorette is the most important place, being a presidio; and besides it there are two missions, Santa Ana and San Joseph; the latter of which has been best known from its having

Mexico.

California.

Mexico. been the station in which the astronomical observations were made, and the transit of Venus observed in 1768, by the French Abbé Chappe and a Spanish astronomer, Don Vincente Doz.

New California, though to the north, and in a less genial climate, possesses a more fertile soil and more numerous population. The inhabitants were estimated at 15,000 in about 2000 square leagues of extent in the year 1802. The settlement of this country has been but recent, being first occupied by Spaniards in 1769. Its increase since that period, with very trifling additions from fresh emigrants, has been singularly rapid. The numbers in 1790 were 7748 souls, in 1800 13,468, and in 1802 15,562. The fertility of the soil is such, as must cause a continued increase, if, as cannot be doubted, the principle is correct that the multiplication of mankind is limited by the quantity of food that can be produced. It is stated, on good authority, that in the year 1791 there were sowed in the whole province 874 fanegas of wheat, the produce of which, at the harvest, amounted to 15,197, or more than 17 for 1. The next season recorded, that of 1802, was nearly as beneficial. The seed sown was 2089 fanegas, and the crop reaped was 33,576 fanegas. The increase of the flocks and herds seems to be keeping equal pace with the produce of the corn fields. In 1791, the black cattle were 24,958, and in 1802 they had been augmented to 67,782; whilst sheep, horses, mules, and pigs, had been similarly increased. As in other Spanish colonies, some impolitic regulations check its growth. The soldiers are discouraged from becoming cultivators, and the monks, who rule the country, rather discourage the settlement of white people, because they are less obedient than the Indians, whom they convert. In spite of these regulations, however, the colony bids fair to become populous and flourishing. The climate is remarkably salubrious, and the fruits of Europe flourish most luxuriantly, especially the vine, from which already some very good wine is made. There are abundance of wild animals, especially stags of vast size, with horns of enormous length, some said to be nine feet long. These animals, called venados, are remarkably swift of foot. They are caught by hunters on horseback, but being swifter than the best horses, they can only be come up to when they stop to drink, when a running noose is thrown over them, in the same dexterous manner in which the Spanish hunters take wild horses and cows. The Indians have a different mode of taking these animals. They place the horns of one on their own heads, and conceal in the bushes every thing but the horns which appear above; the herd approach without fear, and are then killed by arrows. The animals lately exhibited in London, under the name of Wapiti, were of this kind, and though stated by the proprietor to have been caught on the banks of the Missouri, were more probably the venados of California. They had not arrived at their full growth, but one of them was then on the shoulder seventeen hands two inches in height. The capital of New California is San Carlos de Monterey. It has an excellent bay, and good anchorage in six fathom water; and the English ships bound to the fur stations on the north-west coast of America, find re-

freshments there which are highly grateful in their protracted voyages. The other settlements on the coast amount to twelve, whose population varies from 500 to 1500 souls. The whole cultivation, and nearly all the inhabitants, are either in these places or in their immediate vicinity.

From the first conquest of Mexico by the Spaniards, to the invasion of Old Spain by the armies of Buonaparte, that country had continued to enjoy internal tranquillity, and had been free from the exercise and even the alarms of war. During the contests between Spain and England, its communication with the European metropolis had been interrupted, its commerce frequently intercepted, and small predatory bands of enemies had occasionally committed trifling depredations on its smaller maritime towns; but these events had little influence on the progressive improvement of the country, which had gone on increasing in wealth and population, with a rapidity unexampled in the communities either of the old or the new world.

If this state of tranquillity had rendered the practice of arms unnecessary, and removed from the inhabitants all tendency to acts of violence and bloodshed, it had not lessened those more vengeful feelings which seem innate in the human breast, and whose horrible exercise, when the passions became inflamed, is displayed in every form of implacable fury, wanton cruelty, and exterminating revenge.

As the events in Spain, which produced the bloody scenes that Mexico exhibited, are too well known to our readers to require any recital here, to connect the cause with the effect, we may proceed to the narration of the ferocious transactions which followed in Mexico the pretended cession of the Spanish dominions to the family of the occupier of the military throne of France.

The Viceroy of Mexico, at the period of the renunciation of Bayonne, was Don Josep Iturrigaray, a man nearly seventy years of age, undistinguished by any display of talent or energy of character. He was of mild and insinuating manners, and had been sent to Mexico by the influence of Godoy, to amass that fortune which most of his predecessors had made the principal object of their government. The details of administration there, as in all the other colonies, are vested in various *Boards* for the military, ecclesiastical, mining, fiscal, and judicial departments. The court of justice, called the *Royal Audiencia*, though it had no power to control the Viceroy, yet, from its important duties, of a mixed nature, was considered the highest tribunal, and was indeed a species of privy council. On the death or absence of the Viceroy, it exercised supreme power until his successor was appointed. As this is the most powerful body in each colony, care is taken that the majority of its members, called *oidores*, shall be natives of Old Spain, and as the emoluments of the office are very considerable, no small degree of influence, intrigue, and bribery, was usually exercised to obtain the appointment. The merchants of Vera Cruz, and of the city of Mexico, are an important body, and the principal members of it are erected into a board called the *Consulado*, which

Mexico.

Recent History of Mexico.

Mexico. had much influence and power, and considerable intercourse with the audiencia, and like that court consisted almost wholly of natives of Spain. Besides the boards already noticed, the municipal corporations, from their great possessions, had naturally a considerable share of influence; and that of the city of Mexico, containing a population of 140,000 inhabitants with immense estates, had a larger proportion than usually fell to the lot of other Spanish American cities. Those municipalities, called sometimes the *Cabildo*, sometimes the *Ayuntamiento*, and sometimes the *City*, were in their composition not unlike the ancient parliaments of France. Their members called *regidores*, their president, the *corregidor*, and their executive officers, the *syndics*, were chosen from the people, and originally by the people; but by a more recent practice, those offices had been openly sold by the crown, and the purchasers had the power of relinquishing them in favour of any of their own relatives. As the purchasers advanced in life, they most commonly transferred the office to a successor of their own family born within the colony, till, in process of time, the municipal corporations became composed of members, the far greater part of whom were natives of the country or Creoles. These *cabildos*, though not exempt from corruption, nor free from undue influence, and though subordinate to the audiencias, were by far the most independent bodies in Spanish America; and though they had little power except over their own revenues, they could and did remonstrate against any very grievous acts of oppression. The *cabildo* of the city of Mexico possessed a larger portion of the confidence of the people than any other public body, and sometimes assumed, from the popularity they enjoyed, a degree of authority in public proceedings, which it was doubtful, at least, if they were legally entitled to exercise by the laws, entitled "*la recopilacion de las Indias*."

Indistinct rumours only had reached Mexico of the tumults at Aranjuez, of the resignation of Charles the Fourth, the banishment of Godoy, and the proclamation of Ferdinand the Seventh (for the war with England intercepted regular correspondence), till, on the 15th of July 1808, a small vessel from Cadiz arrived with the French *Madrid Gazettes*, addressed to the Viceroy Iturrigaray. The Viceroy assembled the audiencia, and laid before them the intelligence these Gazettes contained of the transactions of Bayonne. By the advice of this body, he was induced to publish these French accounts, without any remarks, or intimation that any injustice had been done, or that any resistance was making, or would be made, to the new dynasty; but cool as the Viceroy appeared, and as the audiencia and the consulado really were on this occasion, the inhabitants of Mexico were thrown into a ferment of indignation; crowds eagerly assembled in the squares and public walks, and vengeance was denounced against France and its adherents, with all the characteristic fury of a Spanish populace.

The *cabildo* immediately presented an address tending to stimulate the loyalty and zeal of the Viceroy and the audiencia; they expressed in strong terms their adherence to the captive family, their

Mexico. detestation of Bonaparte and his tyranny, and their resolution to resist his dominion, by making the sacrifice of every thing dear to them in opposing him. They conclude, "This is the universal resolution of the kingdom, which Mexico, as its metropolis, displays to your excellency and to all the world; its inhabitants are resolved to maintain it with their persons and their property, and will shed the last drop of their blood in its support. In defence of this just cause even death itself will be cheering and delightful; as their career will then terminate with the noble satisfaction of being sons worthy of those fathers whose valour and loyalty they inherit. Mothers will themselves place in the hands of their sons the musket and the sword, that they may fill up the ranks in which their fathers have fallen; and should no other resource be finally left, they with moistened eyes will fire the towns and cities, and embracing their infants, rush with them into the flames, that the enemy may triumph over our ashes, but not over our freedom."

The whole viceroyalty of Mexico was in a state of alarm and confusion, which created a spirit of party, and gave birth to scenes of violence very different from the apathy and indolence which had prevailed for centuries preceding. The audiencia and consulado, all Spaniards looking to Spain for protection, and ultimately as a retirement when they had accumulated sufficient wealth, were afraid lest, if the French family were firmly established, which there was no reason to doubt, the Americans would withdraw all the ties which connected them with the peninsula. The municipality were in dread of being subjected to France, and, by that subjection, being deprived of their laws, and, above all, of their religion; of the excellency of which they affected to be themselves, and certainly made the Creoles, mulattoes, and Indians, deeply impressed. The audiencia and consulado urged on the Viceroy, with all their powers, the importance of following the fortune of Spain under every circumstance; whilst the municipality and the populace demanded a solemn abjuration of France and her partizans, and the immediate assembling of a junta composed of representatives of the different corporations of the kingdom, to assist and maintain the rights of the Spanish Bourbon family. Amidst this collision of parties, the Viceroy hesitated what part decidedly to take, though he gave, when acting without the influence of the audiencia, strong indications of adherence to the popular party.

After fourteen days of dissension, official advices were received that the whole of Spain had spontaneously risen to resist the cession of the crown, and that a body at Seville was appointed as the supreme junta of Spain and the Indies, and had proclaimed the captive Ferdinand king of all the dominions. Immediately on receiving this intelligence, without consulting the audiencia, Iturrigaray caused the young monarch to be proclaimed, and his name used, though without acknowledging, or even noticing, that the exercise of his power was vested in the junta of Seville.

The audiencia then urged submission to the assembly of Seville; the municipality urged the necessity

Mexico. of collecting the representatives of the various corporations; and whilst these two bodies were busily employed in memorializing the viceroy, dispatches arrived from the junta of the Asturias assembled at Oviedo, claiming also supreme authority in the name of Ferdinand. This event furnished a strong ground to the Creoles for demanding a junta, and it was as eagerly resisted by the Spaniards, who feared that, if a popular assembly was once collected, such steps would be taken as must separate Mexico from Spain; if, as they expected, the French dynasty should ultimately be established in the peninsula. In this situation of affairs, because the viceroy declined acknowledging the authorities both of Seville and Oviedo, the members of the audiencia and the other European Spaniards, principally the traders, secretly organised a body of about 250 men, surrounded the palace in the middle of the night, seized Iturrigaray, his wife, and children, conveyed him under an escort to the Inquisition, and by day-break issued proclamations to quiet the populace, declaring him accused of heresy. A charge of this nature so shocked the feelings of a people deeply imbued with superstition, that, under their influence, no movements were made in the metropolis, and the body who had deposed the viceroy conveyed him to Vera Cruz, embarked him on board a ship, and sent him a prisoner to Cadiz. The audiencia, being thus in possession of supreme power, had the means of conveying to the junta of Seville such representations of their own conduct, and that of the viceroy, as best tended to exculpate themselves, and to keep the government of the country in their own hands. They knew that a charge of heresy, that the intention of degrading the image of the Virgin, however calculated to influence the mob of Mexico, would be treated with indignation, or at least with contempt, in Spain. The charge, therefore, transmitted to Europe against Iturrigaray, was of a nature to produce a greater influence on those who ruled in the peninsula. He was accused of designing to establish himself as an independent monarch, and of acting without the control of the junta of Seville. This accusation was effectual; on his arrival, the junta, delighted at having in their power one of those who had opposed their authority, or at least not acknowledged it, consigned him to a dungeon without investigation. He never was brought to any examination or trial; but, after three years' close confinement, when the Cortes published a general amnesty, he was released, ruined in his fortune, his reputation, and his health, and one among many proofs of the villanous injustice of the sovereign people of Spain.

The audiencia, in Mexico, having dethroned the viceroy, assumed the supreme authority, and placed at their head Gálvez, an imbecile officer, more than eighty years of age, who was in every thing ruled by those who had appointed him. His authority was brief, however, as the junta of Seville sent orders for the archbishop to assume the vice-regal character. This ecclesiastic used great and effectual exertions to collect and send to the peninsula large quantities of treasure. His hatred to France, and his love to religion, especially to the Virgin of Guadalupe, the

tutelar saint of Mexico, made him a favourite with the Creole and Indian races; and, as he discovered no great acuteness in detecting the jobs, or the injustice of the audiencia, he was universally respected.

During these changes of government, however, the public not only in the capital, where the transactions had passed, but in the large cities of Guanajuato, Guadalupe, and Dolores, were agitated with alarms and suspicions; and their apprehensions were kept up by the municipalities, who certainly feared, that when Spain was overrun by the French, which they considered inevitable, the intrigues of the audiencia would deliver them over to Bonaparte.

When intelligence reached Mexico, that the central junta was dispersed, and that the French had possession of every part of Spain, except Cadiz, serious indications of insurrections became prevalent; but when it was announced, that a regency, installed by the fugitive junta, had deposed the archbishop, and nominated for his successor General Venegas, who was considered in Mexico as a traitor, who, by his conduct in the command of an army destined to co-operate with Lord Wellington, had rendered the victory of Talavera worse than a defeat, the dread of being delivered over by him to the dominion of France, so filled every mind in the whole kingdom of Mexico with alarm, as to produce an instant and spontaneous explosion. When Venegas reached the shores of his government, he was greeted with the intelligence, that the whole of the territory, whose command he came to assume, was in a state of revolt against the authority of those by whom he was appointed. The disposition to revolt had been much strengthened by the regency, who nominated Venegas, having expressed their approbation of the conduct of the party who had deposed Iturrigaray, and who, instead of censuring, had rewarded with decorations and appointments the individuals who had been most prominent in that transaction. This appeared to the Mexicans to be most decisive evidence of the design of the Regency and of their new Viceroy, to annex Mexico to the fate of Spain, when it should be totally subjected to the Corsican dynasty. The Spaniards had always impressed on the minds of the Americans the highest ideas of the powers of Spain, of the valour of her armies, and the talents of her officers; and this impression was so strong, that the disastrous occurrences of the war in the peninsula could only be accounted for by the Mexicans, on the supposition of treachery in those who affected to conduct the defence of their country.

When popular discontent is diffused through a country so extensively as it was spread in Mexico, a very slight event is often sufficient to rouse it into action. It is said, a plan for a general insurrection was laid, to take place on the 1st of November 1810, but that some events in the city of Dolores, about 50 leagues north-west of the capital, caused the explosion to take place prematurely in the middle of September. The Corregidor of that city, Don Manuel Dominguez, a native of America, was

Mexico. suspected of being engaged in a plot against the government; and information of it having been communicated to the Audiencia of Mexico, he was suddenly arrested in the middle of the night; his colleagues in the municipality alarmed, and suspecting that they also should soon share the same fate, immediately resolved to commence a revolution.

The most considerable instigator of the revolt was Hidalgo, rector of Dolores, a town of 18,000 inhabitants, principally Indians. This man possessed great natural talents, and a degree of activity and exertion not common among the Creoles. He had distinguished himself in the University of Valladolid by his learning and abilities, and though a man of somewhat dissipated habits, had obtained a benefice, producing from 10,000 to 12,000 dollars a year. He had introduced various new branches of industry which had benefited the neighbourhood. He had established a manufacture of earthenware, a plantation of mulberries, on whose leaves silkworms were reared, and had introduced the various processes necessary for manufacturing the silk. He paid great attention to the education of his parishioners, and, by the appearance, perhaps the reality, of excessive devotion to the Virgin of Guadalupe, he was looked up to by the inhabitants as a superior being. When Dominguez was arrested, this priest convoked his parishioners, and addressed them in language suited to their prejudices and their simple understandings. "This day," said he, "I ought to preach my first sermon on the duty of restitution to those we have injured (this is practised in a species of Lent, observed in September in Mexico); but, alas, this is the last sermon I shall ever deliver to you. I lament it, but there is no remedy! The Europeans give us over to the French. You see they have rewarded those who have deposed our Viceroy, they have displaced the good Archbishop who protected us, and have imprisoned the Corregidor, because he is a Creole. Farewell religion, you must become Jacobins! Farewell Ferdinand the Seventh, you must become Napoleonists!"—"No, father," shouted the Indians, "you must preserve us from this evil! The Virgin of Guadalupe for ever! Ferdinand the Seventh for ever!"—"Well," replied he, "then the Virgin and Ferdinand for ever! and now follow your pastor, who has always watched for your happiness." The effect of this harangue was to rouse the natives, who followed the priest to the neighbouring towns, in all which, their numbers rapidly gathering, they collected more than 40,000 men. Three officers of the royal army, who had been fellow collegians with Hidalgo,—Alende, Aldama, and Abasolo, seduced the native regiments to which they belonged, and joined the insurgents.

These men began immediately to organise their force; Hidalgo was declared general in chief, Alende and Aldama lieutenant-generals; their standard was an image of the Virgin Mary, with the motto, *Life to religion, life to our most holy Mother of Guadalupe, life to Ferdinand the Seventh, life to America, death to the wicked government.* A regiment of infantry from Telaya, and two squadrons

of cavalry of the regiment De la Reyna, joined Hidalgo, who began his command by decreeing the abolition of the tribute paid by the Indians, and then led his forces to the north-west, towards the city of Guanaxuto, the capital of the mining district, where the great mass of silver was retained till it was convenient to transmit it to Perote, the principal fortress of the viceroyalty. The city of Guanaxuto and its vicinity contains a population of 80,000 souls; it is situated in a wild and mountainous country, and by its position might be defended by a small military force; but its inhabitants favoured the insurgents. The commander of the regular forces being killed in a first attack with some of his troops, the rest of the soldiers joined the cause of Hidalgo, and thus he took possession of the place, in which he found silver in coin and bars to the amount of more than 5,000,000 dollars. This important conquest was achieved within fourteen days after the commencement of the revolt, by a body numerous indeed, but ill armed, and worse disciplined, and, excepting the soldiers who had joined them, without any military appearance. Some few had fowling pieces, some few swords, many were armed with only knives at the ends of sticks, and some with the ancient Indian weapons, bows and arrows.

Hidalgo, in possession of Guanaxuto, assumed a kind of government there; he nominated officers for a military staff, ordered the bell-founders to cast cannon, established a mint, and coined money, and employed the most skilful mechanics and chemists to direct the working of the silver mines. He received a deputation from Valladolid, a city of 40,000 inhabitants, consisting of the chiefs of the ecclesiastical, civil, and military bodies of that city, who invited him to visit and organise that place, which he entered with considerable pomp and splendour, on the 20th of October. Here another regiment of the royal army, that of Pasquaro, joined the revolt. Plunder was forbidden, and good order was preserved, but to insure this, military execution was inflicted on fifteen of his Indians, who had been guilty of some disorders. From Valladolid Hidalgo determined to march to the capital, and fully expected to succeed in driving the Viceroy and the Spaniards from that city; on his march he was opposed by a small regular army under Truxillo, which, after a sanguinary contest, was defeated, and the remains of which fell back on Mexico to join the Viceroy.

Venegas, however, had taken measures to annoy the insurgents, in the points at which the insurrection commenced. Cadena was dispatched to Queretaro, about 50 leagues to the north-west, with one division, and Calleja to St Luis Potosi, about 100 leagues to the north, with another; by this plan the capital was unprotected, except by the defeated division of Truxillo, and the few Europeans who were hastily formed into volunteer corps. Hidalgo advanced, and appeared before the city; his columns were seen descending the mountains to the number of 70,000 men; but the Viceroy discovered considerable firmness, though he took the precaution to place the treasure and the stores in such a position as to in-

Mexico.

sure their secure transport to Vera Cruz. He relied, however, more on the thunder of the church than on his military powers; the inquisitor and the archbishop were prevailed on to pronounce a sentence of excommunication against the military priest. Hidalgo, about ten years before, had been the subject of a process before the holy tribunal, from which he had escaped, rather by connivance than by investigation. The process was revived, and sentence pronounced by which he was cut off from the church in this world, and condemned to everlasting flames in the next. The Inquisition, in passing its sentences, is accustomed to increase the number of offences, with no more reason than in an English indictment, the prisoner is charged with "force and arms," with "being moved by the instigation of the devil," or with "not having the fear of God before his eyes;" and in the case of Hidalgo, he was accused of denying the existence of hell; and in another part of asserting, that a Pope who had been canonized was in hell. He was accused of adhering to the heresy of Luther, who maintained that the authority of scripture is superior to that of the Pope, and at the same time of denying the veracity of the *Bible*. These accusations and charges he turned into ridicule, in his answer, showed their opposition to each other, and added a profession of faith by no means deficient in orthodoxy. Though this ecclesiastical process had little or no influence on the forces of the insurgents, who had more confidence in Hidalgo's power to absolve, than in that of the Inquisition to excommunicate; yet on the inhabitants of the city, who were previously disposed to rise and join the insurgents, it had a powerful effect, and produced a resistance which saved it from capture.

Hidalgo, whose numerous troops, flushed with their recent victory over Truxillo, had invested the capital, was induced to desist from attempting to carry it by storm, either, as some assert, from a disinclination to the carnage that must have ensued, or, as others think, from his expecting to gain possession of it by negotiation: be this as it may, he delayed to act till intelligence reached him that the divisions under Cadena and Calleja had defeated some insurgent bands, had united their forces, and were marching to the relief of the capital. The chiefs of the insurgents became divided in their opinions of the next operations to be undertaken; and whilst the army under Calleja was advancing on the capital, Hidalgo and his associates trembling for the fate of the important city of Guanaxuto, determined to withdraw from Mexico, and taking a route to avoid the march of Calleja, retired north to secure the treasures in that place. This induced Calleja to change his route and pursue him. Guanaxuto, by nature a strong position, could only be attacked through a defile, to defend which, the insurgents had hastily constructed two batteries. These the troops of the Viceroy stormed, and entered the city, which was delivered to the vengeance of the enraged soldiers, who executed the most inhuman cruelties on all they met, without distinction of sex or age. The leaders of the insurrection, with the greater

Mexico.

part of their military followers, escaped, and collected again at St Luis Potosi; whilst Calleja, with the utmost deliberation, executed the most sanguinary vengeance on those inhabitants of Guanaxuto who had aided, or even acquiesced in the rebellion.

Guadalaxara, one of the most populous cities of the viceroyalty, about 150 leagues north-west from the capital, had, in the mean time, raised the standard of revolt, and towards that part Hidalgo directed his march, strengthened by the addition of numerous bands, that joined him on his route, and encouraged by success in various skirmishes which occurred with small and scattered bodies of the royalists. He was received at Guadalaxara with open arms by the inhabitants; his stores were replenished, his troops recruited and refreshed, and some degree of discipline attempted to be introduced. From Guadalaxara an expedition was dispatched towards the important sea-port of St Blas, which succeeded in capturing it. The indefatigable Calleja, however, gave little respite to the insurgents, but with his handful of troops advanced towards them. Hidalgo having determined to risk a general engagement in defence of Guadalaxara, he posted his army on the banks of a river, on strong ground at the Bridge of Calderon. Calleja came up with him the 17th January 1811. The insurgents were well provided with artillery, some of heavy calibre, but ill appointed and badly worked; their cavalry were the most numerous part of their army, but in infantry they were very deficient. After various attacks which were at first resisted with firmness and success, Calleja succeeded in carrying all the batteries, and defeating the enemy, who abandoned their stores, ninety pieces of cannon, and their wounded, but retired in some degree of order, which the reduced state of Calleja's force could not enable him to prevent. Hidalgo retired on Zaccatecas, a city in the mining district, 125 leagues west-north-west from Mexico, containing 35,000 inhabitants. Here he made a short stay, cast some new cannon, coined money (with the head of Ferdinand), and again filled up his ranks, which the battle at the Bridge of Calderon had thinned. From hence he removed his head-quarters to St Luis Potosi, where one Villeria had collected an army of fresh insurgents. From this point small detachments of guerillas were equipped, which spread themselves over the whole table-land of Mexico, and kept the few partizans of the Viceroy in a state of perpetual alarm and activity. As the provinces to the north had shown a disposition to revolt, Hidalgo removed his head-quarters to Saltillo, a town at the entrance of the only pass through the range of high mountains, that is practicable for wheel carriages, in order to open a communication with Monterey, and from thence to Louisiana, a part of the United States from whence he hoped to obtain some stores and officers.

As the country of New Estremadura, New Leon, and New Santander, were in a state of insurrection, Hidalgo, and the officers of his staff, thought they might pass through with a small force, to organize, and not to conquer it. On the frontiers of these provinces, towards Fort Clayborne, in Louisiana, and to-

Mexico. wards the unreclaimed Indian nations, the Lipones and the Comanches, a few veteran companies were posted; these were privately concentrated, without the knowledge of Hidalgo, who, with his staff, artillery, and baggage, under a very weak escort, advanced towards St Antonio de Bejar, the capital of Texas. A force of 500 men had been sent forward from the Spanish army, and had passed Saltillo, where the main body of Hidalgo's army was quartered, without being noticed. One Ignacio Elizondo, a native of the country, who commanded a party of insurgents, was seduced, with a small body of men, to betray the excommunicated Hidalgo; and, by these three bodies, the whole of the staff, with Hidalgo, Allende, Aldama, the commanders, the artillery and the stores, were surrounded and captured. The officers, upwards of sixty in number, were immediately put to death, and the privates decimated. Thus perished Hidalgo, after a career of seven months, in which he had been the instrument of raising a power which he was unable to wield, but which became the cause of more bloodshed and desolation than even any civil war had before produced. Though deprived of its officers, its artillery, and its baggage, the insurgent army was neither defeated nor dispirited. The party of the Viceroy considered the destruction of all the leaders of the insurrection as the death-blow of their cause, and celebrated the event with much rejoicing; but the leaders appeared to be of little importance, for others, and with more ability, were instantly found to fill their places. Rayon, who had been formerly a lawyer, and had acted as secretary to Hidalgo, assumed the command of the army at Saltillo, which he found to amount to more than 40,000 men. With this force, avoiding an engagement with Calleja, he took post at Zaccatecas, from whence he attempted to open a negotiation that might terminate in a peace between the two parties, each of which claimed the merit of contending for the rights and authority of Ferdinand, and of the Catholic church. Rayon liberated three prisoners of distinguished rank, and commissioned them to propose to Calleja to desist from further hostilities, and to refer every matter in dispute to an assembly, to be immediately convened, of European and Creole Spaniards. To the proposal Calleja replied, "That, for the goodness of his intention, he had merited a pardon, which should be granted, if he would surrender himself and his army, but if he did not, he would march against him, chastise, and destroy him."

Whilst the insurrection began by Hidalgo, and continued by Rayon, was fluctuating with alternate successes and reverses, another, of an equally formidable nature, was supported on the coast of Mexico, bordering on the Pacific Ocean. Morelos, in early life, had served in the corps of royal artillery, and been promoted to the rank of serjeant; he had long left the army, and entered the church, in which he had attained the station of a parish priest, in one of the most populous districts in the neighbourhood of Acapulco. Here, as soon as Hidalgo commenced his operations, an insurrection also burst forth, of which Morelos was immediately declared the chief.

He organized an army, which became formidable for its discipline and numbers, and which successfully repelled the different bodies of Spaniards sent to attack him. At length the Viceroy collected an army, under the command of General Fuentes, to subdue these western rebels. Morelos advanced to offer battle, and an engagement took place at Tixtla, in which the insurgents were completely victorious, the royal army was dispersed, their cannon, stores, and even muskets, which, in their haste, the defeated threw away, became the prey of the victors. Morelos thus became master of the south-west of Mexico, captured the city of Acapulco, entered the province of Oaxaca, and gave orders which were obeyed even to Guatemala. His troops, instead of flying at the appearance of the royal army, resisted boldly its attacks, and at length became generally the assailants.

During this work of havoc, even in the provinces where the royalists had military possession of the towns, the open country was overrun by small bands of guerillas, who lived on the plunder of the country, and massacred, without regret, any Europeans that were unfortunate enough to fall in their way. The royal troops, on their part, wherever they passed, marked their track by thousands of Indians, who, without the formalities of trial, were hung on the trees that bordered the roads, or at the plantations by which they had marched. A mine situated at the entrance of Huasteca was worked by the insurgents, and furnished Morelos with silver, in a place, from the impenetrable nature of the country, secure from all fears of attack. Canas, a chief, occupied some mountains, from which he descended occasionally, and levied contributions, within five or six leagues of the capital; whilst, a little to the south, one Aldama troubled the bishoprick of Puebla, and intercepted the communication between Mexico and the post of Vera Cruz.

At this period the symptoms of insurrection in the city of Mexico became more alarming; the Creoles and Indians within its inclosure became insolent with every new success of the insurgents; and the delusive doctrines of the rights of man began to be propagated, and to annihilate their loyalty to Ferdinand, and their devotion to the Virgin of Guadalupe.

We left two large organized armies, one under Rayon to the north, the other under Morelos to the south of the metropolis, and will briefly survey the progress of each. Rayon was at Zaccatecas, after the abortive attempt at conciliation, to which he appeared always anxiously to look, and to which he addressed several efforts. He was attacked by General Emperan, who commanded a part of the army of Calleja, and repelled him, with the total loss of his artillery, and the dispersion of his men. He then advanced to Zitaquaro, made it his head-quarters, and established a supreme executive council for Mexico, consisting of himself, the curate Verduco, and the General Liceaga. The election was made by the acclamations of hordes of Creoles, Indians, and mulattoes, who were taught that in these acclamations they were exercising their newly acquired

Mexico. sovereignty, and not made dupes of fanatical and intriguing leaders. Whilst exercising all the power of an arbitrary monarch in Zitaquaro, Rayon did not neglect the proper means of securing himself in his strong position, but fortified all the assailable points. The Viceroy concentrated his army to attack a place now the grand focus of the northern rebellion, and having collected a considerable force, he ordered Calleja to proceed against it: after overcoming several obstacles, the attack on the position succeeded, and Calleja obtained possession of Zitaquaro, with its powder-mills, the cannon foundery, and some stores; but Rayon, with his brother directors and the greater part of the army, retreated in safety to Zultepec, a still stronger position, about thirty leagues to the westward of Mexico, and from whence all the force of the Viceroy could not drive them, till the progress of their disorganizing principles had so far weakened all discipline, as to reduce them from an army into a banditti. Calleja, when in possession of Zitaquaro, exceeded the ferocity which he had before exhibited in different places from which he had driven the insurgents. The defenceless inhabitants were massacred by hundreds during the storming, and afterwards the whole property of each individual was confiscated; those who were permitted to live were banished for ever, and all the buildings of the place utterly destroyed.

When Rayon with his force was securely posted, in December 1811, in the strong position of Zultepec, dissensions began among the chiefs, which were the necessary result of the disorganizing principles they had infused into their ignorant and ferocious followers; all would be rulers, none would be ruled; and those men who had shown courage when opposed to their enemy, discovered equal hardihood in overturning all authority. In close connection with Morelos, who in the field displayed the talents of an able commander, Rayon rather became the civilian, and with his co-directors, issued proclamations and decrees, made solemn declarations of the sovereignty of the people, and attempted by wire-drawn distinctions, incomprehensible to his followers, to reconcile the sovereign authority with that of Ferdinand, whose name he still continued to use. At Zultepec he coined money, and established a printing press, from whence he issued a Gazette, entitled *Ilustrador Nacional*, which was very rudely executed with wooden types cut for the purpose by a native Indian, and printed with indigo. The only military achievement of Rayon, beyond the occasional excursions made by his troops to levy contributions, was an attempt to take possession of the town of Toluca, which the royalists had fortified. He besieged it, but from the want of skill, and having neither heavy guns nor mortars, he failed in the attempt, and withdrew his forces to Tenango, where he was attacked, and though posted on strong ground, was compelled to retreat. In consequence of this reverse, he and the rest of the directory, with all the members of the government, were compelled to abandon Zultepec, and lead a vagrant life; wandering with the army through the northern districts, sometimes affecting to convene a national convention, at other

times almost without food to keep together any considerable force: in fact, the contest had been carried on with so much fury, the scenes of the operations were so extensive, and the numbers collected in arms by the insurgents were so large, that the little cultivation which that rich soil requires was almost totally omitted, and famine contributed to add its share to the mass of suffering which the country endured.

In the beginning of the year 1812, considerable reinforcements of European troops had arrived from the peninsula, where the Cortes, though pressed on all sides by the French, contrived to spare some regiments, both from Galicia and Andalusia, which were joined by a division formed in the island of Cuba. Venegas was superseded in the Viceroyship by General Calleja, who seems to have obtained the appointment by his own representations of the ferocious cruelty with which he treated the insurgents, which was more approved by the government at Cadiz, than the slight traces of humanity that Venegas had discovered.

Whilst these reinforcements were arriving and forming, Morelos was not idle, but discovered, considering the nature of his troops, and the deficiency in stores and ammunition, considerable military talents. We left him in possession of the southwest part of Mexico, and commanding the coast from Acapulco to Costa-Rica. In that unhealthy country his men suffered from an epidemic fever, which induced him to advance to the high land; but he took an easterly direction, marching in two divisions, one towards Chantila, which he surprised, and the other towards Xalapa. He defeated the Spanish General Saavedra, entered the large mining city of Tasco, and occupied the whole mining district between the city of Mexico and Vera Cruz, and thereby prevented the capital from maintaining any connection with the sea. He continued to enjoy uninterrupted success for a long period; the town of Trucar was his principal depot, which resisted a regular siege, and repulsed the attacking army, whilst with his main body he almost surrounded the capital, and reduced it nearly to a state of famine. The newly arrived troops from Spain, who pompously denominated themselves "the conquerors of the conquerors of Austerlitz," were unable to withstand the rude attacks of these Creole bands, and were defeated in several battles, or rather large skirmishes; and, during the time they had passed in the vicinity of Vera Cruz, the dreadful fever of the country had considerably thinned their ranks. The communication between the capital and Vera Cruz entirely ceased in March 1812, and continued closed till the September following. Morelos took the city of Orizaba, in which he found money, tobacco of the king, and various stores, valued at more than 12,000,000 dollars. The disinclination to the service among the troops in the Spanish armies caused numerous desertions, and plans were formed, though, before the execution, they were detected, and the traitors put to death, for delivering up to the insurgents the castle of Perote, the strongest fortress in Mexico, where the treasure is collected; and the castle of St Juan

Mexico.

Mexico. de Ulloa, which commands the city of Vera Cruz. The city of Mexico was filled with rebels ready to rise and drive away the Viceroy, and was only kept in subjection by a rigid police, which filled every public building with suspected persons; forbade more than three men to converse together; and put to death some of the most respectable of those who were known to have favoured the insurgents. The defalcation in the revenue and the mint is a plain display of the distress to which the government was reduced. The *Alcavala* in the capital, a tax of six per cent. on all exchanges of property, usually produced 100,000 dollars monthly; its receipts were reduced to 8000, and the mint, which, before the disturbances, coined annually 27,000,000 dollars, in the year 1811 coined but 5,000,000, and in 1812 but 2,000,000; and, even for this purpose, the plate of all individuals was put in requisition by the Viceroy. Sanchez, a curate, acting under Morelos with five divisions of from 5000 to 6000 men, each occupied the whole of the plains of Puebla, the country of Tehuacan, and Orizaba, quite up to Xalapa. Calleja, with the only official royalist force, watched Morelos, whom he had contrived to separate from Rayon and Sanchez; and at last besieged him in Quautlan, which he had made his head-quarters, and in which his principal stores were collected. The town of Quautlan is situated on a rising ground, in the midst of a large plain, every part of which may be commanded from it. It is a large place, half a league in length, and a quarter in breadth, protected on one side by a rapid river, and on the others by strong walls, flanked by redoubts. The numerous party collected within the town soon produced famine, and an epidemic fever, which was more favourable to the besiegers than their cannon and bombs. The distress was great, and Morelos attempted to open, by a sally, a communication with a body of insurgents, who surrounded, and far outnumbered the besieging army; but the military skill and discipline of the troops under Calleja caused the sally to be unsuccessful; it was, therefore, necessary to abandon the place, and force a passage to their party. Morelos, in the middle of the night, formed a column, in the van of which were 1000 fusileers and 256 light horse, followed by 4000 lancers, then the carriages and light artillery, then the slingers and archers, and the rear-guard of infantry, with a regiment of cavalry. With this force he penetrated the lines of Calleja, and though with a tremendous sacrifice of the lives of his followers, extricated himself, his officers, and part of his troops, from the circle in which they were supposed to be securely inclosed, and in which he had sustained the attacks of a body of disciplined troops, supplied with cannon and other artillery, during seventy-five days, amidst privations and diseases, which had cost him half his army.

After disembarassing himself from this perilous situation, Morelos filled up his vacant ranks, and in spite of an obstinate resistance, captured the town of Chilapa; here he offered to exchange his prisoners, which Calleja having refused, he put to death all the royalist officers and one-tenth of the privates

Mexico. in his power; hoping, as he expressed it, that this painful act of retaliation would put a stop to the inhuman practice which he charged his opponents with having commenced. He then entered Tehuacan, where he burned tobacco, belonging to the king, valued at 6,000,000 dollars. The Generals Sanchez and Montezuma (the latter a descendant of the kings of ancient Mexico, but a priest of a large township in the bishopric of Puebla, and distinguished by his virtues and talents) successfully attacked a division of the royalist army in St Augustine de Palmar, and succeeded in cutting off the whole; putting to death those few who surrendered, so that not a single individual of the garrison was left alive. A reinforcement of 1500 men landed at Vera Cruz from Europe; but after an ineffectual attempt to march into the country and join the royalists, they were shut up within the walls of that pestiferous city, and there, by scarcity of provisions and the black vomit, in less than six weeks their effective force was reduced to half their original number. In order to effect a junction with these troops, and to relieve the distress of Vera Cruz, the Viceroy drew together the forces which had been employed in the siege of Quautlan, and joining them with such others as he could collect, forced a passage by Cordova, and with 1800 mules loaded with flour, put a period to the famine, and returned to the high table-land with a reinforcement of 700 or 800 men only of those recently arrived from Spain.

Though the Viceroy had thus gained some additional force in men, and considerable supplies in stores, he was reduced to merely defensive operations, and could not hinder the insurgents from possessing themselves of any of those places in which they could collect treasure or stores, or destroy the king's tobacco, which, from the cessation of mining, had become the principal resource of the royal revenue.

After burning the tobacco of the three preceding harvests, which was stored in Orizaba, valued at 10,000,000 dollars, Morelos proceeded to Oaxaca, the district in which cochineal is produced. He attacked the capital Antiquera, and, after a sharp contest, entered that city, and acquired a considerable quantity of its peculiar production, as well as of other riches. By a very sensible letter which we have now before us, written from thence by a lady, the wife of a Spanish officer, who had escaped at the capture, it appears that Morelos was busily employed in drilling his army, inspecting their appointments, and providing them with stores; but he suffered no plunder, and permitted no cruelties; that he organized the courts of justice with all due formalities, preserved the greatest attention to all religious ceremonies; and though he put to death two Spanish officers of high rank, it was only in retaliation for two of his chiefs, Lopez and Armento, who had been executed in that city a short period before. He collected the remains of these men from the graves where they had been buried, and from the edifices on which they had been exposed, enclosed them in sumptuous coffins, made a grand procession to the Episcopal

Mexico. church, and interred them with all the most impressive rites of the Catholic religion.

The regular force, under the immediate command of Morelos, at this period amounted to 18,000 men; 10,000 of whom were regimented and clothed in uniform, and armed wholly with muskets, which, at different periods, had been taken from the royalist army. One of the royalist party, writing from Mexico in March 1813, adds, "Thus Morelos has secured a formidable army, after having been engaged in forty-six battles great and small, none of which he lost, and having, by his skilful retreat from Quautlan, demonstrated in the judgment of his opponent Calleja very superior talents."

During the whole of the year 1813, though considerable reinforcements to the royalist army arrived in Mexico, they were insufficient to enable Calleja to assume an offensive war, and though, on the other hand, a small force organized in the United States by Toledo, who had been a member for Mexico in the Cortes at Cadiz, invaded the northern provinces, they were defeated by the royalist General Arredondo, and the remnant effected their escape to New Orleans.

Morelos, in the latter end of 1813, made an attack on the city of Valladolid, in which he was repulsed, and being obliged to raise the siege, he retreated towards Puran; he was followed by the royalist army under the command of Llano, when a battle was fought, in which Morelos was defeated, and his second in command, Matamoros, with 700 men, were taken prisoners. Matamoros had a few days before taken 500 prisoners, and sent them for safety to Acapulco; these Morelos proposed to exchange for the prisoners taken at Puran, but Llano rejected the proposal, and put the whole to death; upon which Morelos ordered the 500 prisoners at Acapulco to be massacred, which was immediately executed. Such was the barbarity with which this furious and extended contest was carried on!

This defeat of Morelos gave a superiority to the royalists' cause, and fresh reinforcements having arrived, they were enabled to begin offensive operations, when the release of Ferdinand from captivity, and his return to his capital, was announced in Mexico. The leaders of the revolt calling themselves the national legislature, which had been driven from Zultepec, consisted only of Rayon, Liceaga, and Cos. These three men had exercised a species of mock government over the various bands; but having defended their conduct on the metaphysical principles of the French Convention, transmitted through the Cortes of Cadiz, they were, in conformity with those principles, compelled to call a congress, which met at Chilpancingo, and practised the same silly mimicry of decreeing abstract doctrines, as had marked the two European assemblies. Whilst debating on many whimsical subjects; whilst striving to conciliate their doctrine of the sovereignty of the people with that allegiance they still professed to Ferdinand,—the news of his release reached them. The more sober part were disposed to suspend their declaratory projects, and wait the result of the situation of affairs, which the establishment of the

power to which they owed and professed subjection might produce; but the more violent, as is usually the case in such assemblies, overcame the more prudent; and instead of waiting calmly, or attempting to obtain a truce, they issued some arrogant and menacing proclamations, which seem to have precluded the possibility of negotiating, even if Calleja had been disposed to enter into them.

Calleja had been promoted to the government at Cadiz, on account of the severities he had practised and the zeal he had displayed. When the king was restored he was continued in the command, and as all the representations of the state of affairs in Mexico received by the monarchical government in Madrid came from him, they were tinged with that colouring which it was deemed necessary to give them, in order to justify the cruelties he had practised, and to induce Ferdinand to continue both the commander and the system, though they had hitherto produced only death and desolation. When a conciliatory proclamation of Ferdinand reached Mexico it produced a temporary pause, which, if Calleja had not been filled with ideas of vengeance, and the insurgents with the fatal whims of democracy, might have led to general tranquillity; but whilst the former only issued offers of pardon, to which the rebels could give no confidence, and to which, as appears by his own intercepted correspondence, none was due; the congress was busily employed in framing one of those ridiculous and impracticable plans, which, in the school of jacobinism, have been called *Constitutions*. It was founded on none of the customs or habits of the country, coincided with none of their prejudices, respected none of their institutions, and was only fitted to be the puppet of a day, and then to be neglected even by those who had framed it. Morelos, whose views were more practicable than those of the others, was too much occupied in the peculiar business of the military, to give a tone in the political disputes of the congress, otherwise he perhaps might have prevented some of the absurdities of which that body was guilty.

The new constitution renouncing allegiance to Ferdinand, and declaring Mexico an independent republic, was promulgated in October 1814; and, under this character of an independent state, privateers were fitted out, manned with the refuse of all nations, and encouraged, by a few secure asylums, to plunder, in the Gulf of Mexico and the Caribbean Sea, the peaceful ships of traders. Emissaries were sent to the United States to procure arms, ammunition, and officers. There Toledo, the member of Cortes, whom we have before noticed, succeeded in engaging General Humbert, who had formerly landed in Ireland, to join the Mexican army; they landed with some arms and ammunition, and proceeded in safety to a small fortress on the road between Vera Cruz and Xalapa, where, according to a preconcerted plan, Morelos was to have joined them; but the latter having been intercepted in his route, which he had undertaken with a small escort, was attacked by a body of royalists, his escort defeated, and himself made prisoner. Having thus fallen into the hands of the

Mexico.

Mexico.

Viceroy, he could expect no favour; he was accused before the Inquisition of heresy, but that tribunal refused to condemn him, or rather hesitated so long, according to its ordinary forms, that Calleja ordered him to military execution; yet such was the veneration in which he was held by all the inhabitants of the city of Mexico, that the government feared his execution there would produce some convulsion, and sent him secretly to an obscure village at six leagues distance, where he was shot in the back to indicate that he was a traitor.

With the death of this extraordinary man, every rational prospect of success to the insurgents was at an end. The democratic assembly convened under the fantastic constitution met at Tehuacan, and, as usual in such assemblies, spent its time in silly debates about the limits to be prescribed to the executive power, whilst they neglected to strengthen the armies, or to provide them with ammunition. After some time spent in personalities, an ape of Cromwell, or of Bonaparte, appeared in the person of Don Miguel Teran; he had been a partizan soldier, but at length became commander of the guards, the best disciplined corps in the service of the republic. This man, in December 1815, about one month after the death of Morelos, surrounded the hall of assembly with his guards, entered it with a detachment, expelled the members, and associating with himself two other persons, Alas and Cumplido, assumed the supreme power, and abolished the constitution. The irregular despotism, generated in democracy, was unequal to contend with the more consolidated despotism exercised by Calleja. Teran had hopes of assistance from the United States. Joseph Bonaparte, who had arrived there, was destitute of money, or unwilling to risk it in another royal speculation, and though he amused the insurgents with some hopes of assistance, and they flattered him with some prospect of being again a king, it terminated with the disappointment of the expectations of all the parties.

Calleja was strengthened by fresh troops, while the insurgents in numerous bands were scattered over the country, which they laid waste, but retreated as the royalists advanced. He thus describes them: "These bands are not sufficiently powerful to defeat the regular troops, to take towns, or to intercept the convoys; yet we have not strength enough to destroy them, but they are frequently defeated, often harassed, and always severely punished if they fall into our power."

During the whole time that Calleja ruled in Mexico, the predatory bands continued to commit depredations; a species of warfare more afflictive than any operations carried on in regular contests. The country became sick of the calamities it suffered, and the voice of conciliation was more wanted than reinforcements of troops. Milder councils at length prevailed in the cabinet of Madrid, and the execution of them was entrusted to the best hands in which they could be placed. Admiral Apodaca is too well

Mexico.

known in the first circles in this country to require any eulogium; and as he went to Mexico, the herald of peace, he succeeded in lessening the irritation that prevailed, and reconciling the most respectable of the chiefs to his mild administration. Rayon, the most considerable, has accepted the terms that have been offered; and he and his whole army have laid down their arms, and taken the oath of allegiance to Ferdinand. We are unacquainted with the terms on which the conciliation has been effected; but as Rayon, during five years, contended with vigour, even after severe reverses against the royal troops; as his whole conduct, during the continuance of the contest, was marked by the most determined resolution, we may fairly conclude, either that the terms proposed were advantageous to his party, or that the expectation of success was so small, that further hope could not be entertained.

We need scarcely notice the expedition of Mina, who was equipped by some speculators in Europe for the conquest of Mexico. He was little acquainted with the dispositions of the inhabitants, and less with the nature of the country and the paucity of its resources. After effecting a landing to the north of Panuco, he penetrated into the country, where he was surrounded by the royalist troops, was taken prisoner with most of his followers, and at length received his death from the hands of the executioner.

From the execution of Mina, the tranquillity of Mexico was gradually returning, though occasionally interrupted by small assemblages of rioters rather than insurgents. They were dispersed, though not without the loss of some lives in the field, and of others on the scaffold.

The recent events in Spain, as far as certain intelligence has yet (20th September 1821) reached us, appear to have produced an effervescence in Mexico which has led to riotous assemblages in some parts of the viceroyalty of great, but perhaps of exaggerated extent. The communication between the capital and the coast has been occasionally interrupted, but never closed, when the Post was attended by an armed escort.

It is, however, too much to be feared, that a country in the circumstances of Mexico will continue to be the theatre of bloody contests as long, at least, as the metropolitan government in Europe shall remain in its present unsettled and revolutionary state.

Middlesex. **MIDDLESEX**, an English county; and though in extent one of the least, yet, as containing within it the metropolis of the British empire, with its numerous population, its extensive wealth, and its repositories of art and science, and being the theatre of the most interesting historical and political transactions, naturally attracts to it the attention of all who are connected with the united kingdoms.

Boundaries and Extent. This county is bounded on the north by Hertfordshire; on the west by Buckinghamshire; on the south by Surry, and at the eastern point by a small portion of Kent; and on the east by Essex. Its general figure is quadrangular, but rendered very irregular by the course of the rivers Thames, Coln, and Lea, which bound it on three sides, and by a considerable projection into Hertfordshire on the north. Its greatest length is twenty-three, and its greatest breadth seventeen miles. Its square contents are estimated at 285 miles, or 182,400 statute acres.

According to the census of the year 1811, the number of inhabitants was 953,276, of whom the males were 491,633, and the females 461,643. The number of families was 222,010; of whom 9,088 were employed in agriculture; 135,398 in trades and professions; and 77,524 were occupied in other pursuits. The marriages, in the year 1810, were 11,026. The baptisms of males were 11,859, of females 11,701. The burials of males were 11,370, and of females 11,026. The registers of baptisms and of burials are less certain criterions of their proportions to the population, than those of any other district in the united kingdom, from the greater comparative number of sectaries, whose births and deaths are unnoticed, especially births, in the parochial registers.

The population of the places, whose numbers exceed 2000, are as follow :

London (within the walls),	-	55,184
London (without the walls),	-	65,425
London suburbs, exclusive of those villages marked thus *, which are also subarbal,		367,370

The face of this county may be described as a gentle sloping track rising from the banks of the Thames, its southern boundary, to the hills on the north, none of which rise more than 350 feet above the level of that river, and few even attain that height. In receding from the banks of the stream, the surface is gently undulated, with sufficient slope to secure the necessary drainage. The prospects in the southern division of the county, from the level nature of its surface, are not distinguished by extent or variety, and the eye is only relieved from the fatigue of uniformity, by the numerous buildings, plantations, gardens, and the rich verdure of productive grass fields. Even on the more hilly parts of the county the prospects are far less impressive than those on the opposite banks of the Thames, or than those which are to be seen on the borders of that river before it enters Middlesex. The best prospects of a rural kind are from the range of hills stretching from Pinner, Stanmore, Elstree, Totteridge, and Barnet, to the forest scenery of Enfield Chase. The Hill of Harrow, a projection from this ridge, is one of the highest points, and the whole of the richly cultivated valley of Middlesex is comprehended in the view from it.

The original soil on the southern side of the county is of a most sterile kind of gravel; but the vast quantities of manure which have been furnished to it from the extensive cities in its vicinity, have been so spread on the surface, that a most luxuriantly productive soil of garden mould has been created, and from the same cause is renewed as rapidly as it becomes exhausted by the crops grown upon it. The northern part of the county generally consists of a soil of clayey loam, which, though rather difficult to plough, is, when properly pulverised, very well adapted for the cultivation of wheat, and has been long celebrated for the excellent quality of that grain which is produced upon it. The table of Queen Elizabeth was regularly furnished with white bread from the wheat grown in the vicinity of Hounslow. In several parts of the county the loamy clay, converted by the addition of cinders, technically called breeze, into bricks, becomes the most profitable application of the soil. This is peculiarly the case where such soil is found in the immediate vicinity of the metropolis, or on the banks of the rivers or canals that communicate with it. "Round the one mile-stone on the Kingsland road," says Mr Middleton, "the surface is lowered from four to ten feet, by the earth having been dug up and manufactured into bricks, over an extent of more than 1000 acres; and it has been levelled, ploughed up, and laid down to grass. It is sufficiently dry, and by the help of town manure, is restored again to

Middlesex. excellent grass land; though it had previously yielded to the community, through the medium of the brick-makers, upwards of L. 4000 *per acre* on an average of the whole level; but there are a few acres of choice marl earth, which have produced through the same medium L. 20,000 *per acre*."

Agriculture. The greater portion of the land in the county is appropriated to the cultivation of grass, which is converted into hay for the supply of the numerous horses kept in the metropolis. These upland meadows have been gradually extending as the metropolis has increased, so that at present not more than 20,000 acres are under culture by the plough. The meadows, however, even those which have been longest laid down to herbage, discover the marks of their having been formerly ploughed. The great consumption of hay in the London markets has induced the most skill to be applied to that particular branch of rural economics which, under the term hay-making, is usually deemed the simplest of all agricultural operations, but is here managed in so superior a way as to bring to the stack hay of a quality far better than is preserved in the more distant counties. The corn grown in this county is inconsiderable; on an average of years, about 10,000 acres are sown with wheat, about 4000 with barley, about 3000 with beans, and about 2000 with pease; some rye is grown, but principally for green food, and scarcely any oats are cultivated. There are fewer sheep and cows kept in Middlesex than in any other county; but of the latter some thousands are maintained solely for the purpose of supplying milk for the daily consumption of the metropolis. Many pigs are fattened from the offal produced in the vast breweries and malt distilleries of London and its vicinity.

Horticulture. The horticulture of Middlesex, though it does not extend over quite so great a surface as its arable culture, produces a far greater annual return. Exclusive of the gardens attached to the houses of the nobility and gentry, the extent of land appropriated to the growth of fruit is reckoned by Mr Middleton to be 5000 acres, of that devoted to culinary vegetables 10,000, and of that used as nursery grounds and plantations 1500. The same writer estimated the annual value of the productions of horticulture at somewhat more than one million Sterling. The gardeners of Middlesex practise a wonderful economy in the raising of crops. The fruit gardeners have what they call an *upper* and an *under* crop growing on the same ground at the same time. First, the ground is stocked with apples, pears, cherries, plums, walnuts, &c. like a complete orchard, and called the *upper* crop. It is secondly fully planted with raspberries, gooseberries, currants, strawberries, and all such fruits, shrubs, and herbs, as are known to sustain the shade and droppings from the trees above them without the least injury: thus they term the *under* crop. Some of these gardens have walls which are completely clothed with fruit trees, such as peaches, nectarines, apricots, plums, and various others, all adapted to the aspect of the wall. In order to increase the quantity of warmth and shelter in autumn, they raise earthen banks of about

three feet high, laid to a slope of 45° to the sun. On these slopes they plant endive in the month of September; and near the bottoms of them they drill pease from October to Christmas: by this means the endive is preserved from rotting, and, as well as the pease, reach maturity at an early period. The common routine of the best kitchen gardeners is the following: Soon after Christmas, when the weather is open, they begin by sowing the borders, and then the quarters, with radishes, spinach, onions, and all the other seed crops. As soon afterwards as the season will permit, which is generally in February, the same ground is planted with cauliflowers, from the frames, as thick as if no other crop had then possession of the ground. The radishes, &c. are soon sent to market; and when the cauliflowers are so far advanced as to be earthened up, sugar loaf cabbages are planted from the before mentioned seed crops; and daily as these crops are sent to market, the same ground is cropped with celery for winter use. The foregoing rotation is the common practice, but there are many deviations according to the judgment of the cultivators, the state of the weather, and the demands of the market; but such a system can be pursued only in the vicinity of great cities, whose abundant manure gives the means of raising vegetable productions in defiance of the inclemency of our northern winters. A species of cultivation of a non-descript kind, partaking of the nature of agriculture and horticulture, is extensively pursued in this county. The ground is ploughed in January and February, and cropped with early pease, which are gathered green in June. The land is then sowed with turnips, which are sold in autumn, when the kind of cabbages called collards are planted, and these three crops are annually raised from the same soil.

The manufactories in the county of Middlesex are very numerous, and though, from the comparatively high prices of labour, rent, and fuel, few of the more coarse articles of consumption are made, yet the finer or more curious kinds of commodities are extensively produced in the vicinity of the metropolis. The manufacturers that employ the largest capitals are the brewers and malt distillers. The printing of calicos of the superior kinds, is conducted on a large scale at Isleworth, Staines, Old Ford, and some other places, but bearing no comparison in extent to similar establishments in the north of England and in Scotland. The silk manufactures, originally established by French Protestant refugees in the parish of Spitalfields, have been ever since continued; and though colonies from them have been transplanted to Coventry, to Staffordshire, Lancashire, and other parts of the kingdom, that branch of industry is the employment of nearly 40,000 persons. Ship-building and the various auxiliaries of that art, such as rope-making, sail-making, block and anchor-making, copper sheets and bolt-making, and numerous other appendages, are conducted on a very extensive scale. The other manufactures are so various, that it is scarcely possible to enumerate even the considerable ones. Of these the most prominent are watch-making, glass-blowing and cutting, dyeing, chemical preparations

Middlesex. for dyers and medical purposes, paper and pasteboards, gunpowder, china and earthenware, bricks and tiles, turnery ware, musical and mathematical instruments, cutlery, surgical and philosophical implements, gold and silver lace, gold and silver ornaments and utensils; and to these may be added carriages for luxury, and ornamental furniture for dwellings of every description.

River. The rivers of Middlesex are the Thames, the Coln, the Brent, and the Lea. The former of these is navigable for barges, for almost its whole extent, to Lechlade in Gloucestershire, within a few miles of its source. The tide is felt as high as Teddington, above which the navigation is performed by penning the water at various locks till a sufficient body is collected, which, by making what is locally called a *flash*, permits the passage of the barges over the obstructions and shoals, which, a few hours after, become again impassable. The picturesque beauties on the banks of this stream are too well known to need a description in this place. The Coln is unnavigable. It enters Middlesex from Hertfordshire at the north-western extremity of the county, and falls into the Thames in various channels at considerable distances from each other, having in its course been applied to the working of numerous mills for paper, corn, and other purposes. The Brent, also unnavigable, enters the county from Hertfordshire, and joins the Thames at Brentford. The Lea is navigable for barges in its whole course through this county. It enters from Hertfordshire, forms the eastern boundary of Middlesex, and joins the Thames at Limehouse below London. Besides these natural streams the artificial one called the *New River* belongs to this county. The artificial channel in which this stream flows towards London has a very devious course, in order to keep the waters at a due level. It is ultimately received into a spacious reservoir near Islington, from whence, by means of pipes, its water is conveyed through the streets of the metropolis to the houses of individuals.

Canal. Among the public works of this county, the canals deserve notice. These are the Grand Junction, the Paddington, and the Regent's. The first forms a connection with the whole interior of the kingdom, and the second is connected with it. Through them, internal navigation is conducted to the manufacturing counties, and to the distant ports of Liverpool, Bristol, and Hull, and to the potteries, iron-founderies, and collieries of Staffordshire and Warwickshire. The Regent's Canal, recently completed, surrounds the whole of the northern side of the metropolis, around which it describes a semicircle, commencing at the dock of the Paddington Canal,

and terminating at the river Thames at Limehouse. **Middlesex.** Its principal utility is supposed to be derived from forming the means of conveying coals and other heavy commodities from the river to the more distant parts of the capital without expensive land carriage.

The docks constructed, of late years, for the facilities of commerce, are most extensive and magnificent works, and the warehouses that surround them are wonderful exhibitions of the commercial opulence of this country, having been all completed from the capitals of individuals. The West India Docks contain about sixty acres of water, in which the largest vessels can float. The London, or Wapping Docks, are of nearly the same extent. The East India Docks are more than thirty acres, and near them is a dock belonging to private individuals (Messrs Wigram and Green) of nearly twenty acres, where the business of ship-building is carried on upon a scale that exceeds most of the establishments of the governments of Europe.

The most remarkable edifices of this county are more properly described under the articles LONDON or WESTMINSTER in this work. Beyond the limits of those cities must be noticed the palaces of Hampton Court and Kensington; the Hospital of Chelsea for invalided soldiers; the Royal Military Asylum; the bridges of Staines, Vauxhall, and Waterloo; the archway under Highgate hill; Middlesex Hospital; St George's Hospital; Jews' Hospital; and Harrow School. The number of other erections, of a second and third order, are too numerous for recapitulation.

The changes of property have been so rapid in this county, and the taste for substituting fashionable novelty in the room of venerable antiquity has been so prevalent, that very few first rate seats are to be found, but a vast number of second and third rate houses, which, if removed from the vicinity of the metropolis, would attract considerable notice. The most remarkable residences are Bently Priory, Marquis of Abercorn; Brandenburg House, Margrave of Anspach; Bushy Park, Duke of Clarence; Cœnwood, Earl of Mansfield; Chiswick House, Duke of Devonshire; Fulham Palace, Bishop of London; Holland House, Lord Holland; Littleton, Thomas Wood, Esq.; Osterley House, Earl of Jersey; Sion House, Duke of Northumberland; Strawberry Hill, Countess of Waldegrave; Wrotham Park, George Byng, Esq.; Cannons, Sir Thomas Plummer; Bush Hill Park, William Mellish, Esq.; Harrow, Lord Northwick; Sion Hill, Duke of Marlborough.

MINERALOGY.

Mineralogy. **MINERALOGY** is that department of Natural History which makes us acquainted with all the properties and relations of minerals. It is divided into two grand branches, viz. Mineralogy, properly so called, and Geology. Mineralogy treats of the properties and relations of *Simple Minerals*; while Geology considers the various properties and relations of the *Earth, Atmosphere, the Waters of the Globe, and the Mountain Rocks*, or those mineral masses of which the crust of the earth is principally composed, and which are generally of a compound nature.

I. MINERALOGY.

1. *System of Arrangement.*

The arrangement of simple minerals has always been a subject of controversy with mineralogists; and the discussions to which it has given rise have materially contributed to the advancement of our knowledge of the natural and chemical history of minerals. Many, as Berzelius and others, contend for the Chemical arrangement, according to which the species are grouped in conformity with their chemical composition and characters; others, as Werner, Hoffman, &c. reject the pure chemical, and adopt the Mixed Method, in which the species are arranged and determined according to the conjoined external and chemical characters; and of late years the Natural History plan, or the arrangement according to external characters alone, has been advocated by Mohs, Jameson, &c. We are inclined to recommend the latter; and of all the natural history arrangements, we consider that of Professor Mohs as the most philosophical, and we have accordingly adopted it in the present article.

2. *Characters of Minerals.*

As the characters employed in the natural history system of mineralogy are principally those named external, we shall here confine our attention to these, referring for an account of the others to the article **MINERALOGY**, already published in the *Encyclopædia Britannica*. We shall first give an account of the characters used in the construction of the different principal divisions of the system; and next enumerate and define those characters which are employed in the *description* of the species, subspecies, kinds, and varieties of simple minerals.

I. CHARACTERS EMPLOYED IN THE DETERMINATION OF THE CLASSES, ORDERS, GENERA, AND SPECIES.

I. Regular Form.—II. Cleavage.—III. Hardness.
IV. Specific Gravity.*

I. REGULAR FORM.

Mineralog

1. *Simple and Compound Forms.*

The first step Crystallography takes in the consideration of the regular forms occurring in the mineral kingdom, is to distinguish them into *simple* and *compound* ones. A simple form is contained under *homologous* planes, or such as are equal, similar, and equally disposed in respect to each other; a compound one is contained under planes, *not homologous*, or such as are not equal, similar, and equally disposed to each other.

2. *Combinations.*

A compound form is termed a *combination*. The combinations consist of the simple forms, and each face occurring in them, belongs to a particular simple form, in as far as it is not homologous with others.

3. *Edges of Combination.*

The edges, in which the faces of different forms meet or intersect each other, are called *edges of combination*. The denomination of the edges between the homologous faces depends upon the simple forms themselves, or upon their peculiar situation, and their other qualities.

4. *Development of the Combinations.*

An object of the greatest importance for crystallography is the illustration of the *development* of the combinations. A combination is developed by showing of what simple forms it consists, and in what relations those simple forms are to each other. The manner in which this is done is as follows: First, the connection existing among certain simple forms is exhibited; and these simple forms are arranged accordingly into series, the members of which, between certain limits, follow constant laws, and are known in all their geometrical relations, if it is possible to determine their distance from a known member, or to assign them their relative position in a series, which contains the same member. The position of a member in the series is determined by considering the situation of the edges of combination; and the development of the latter will, therefore, depend upon two points; first, to make out the kind of the simple forms they contain; and then, from the observed situation of the edges of combination, to determine to which member of the afore-mentioned series they belong, or which places they occupy in this series.

5. *Preparation for the Development of the Combinations.*

Let fig. 1, Plate XC(VIII), be a combination of two

* Certain varieties of *colour*, the *lustre*, and also the *streak*, are occasionally used in forming the characters of the systematic divisions.

Mineralogy rhomboids. The faces ADEED, ADE'E'D,...belong to one, the faces DFE'E'E'...to the other. Let the edges of combination DE, DE',...be parallel, and the faces of the two forms that meet in them equally inclined to each other. The plane angles at the apex, or at the solid angle formed by three equal plane angles of the former, are smaller than the same of the latter; and likewise the inclination of the *terminal edges*, or at those which terminate in the apex, or in the terminal point of the axis AX of the former, is smaller than the same of the latter, which, therefore, is called the *more obtuse*, whilst the former bears the denomination of the *more acute rhomboid*. It would not be sufficiently intelligible to derive the relation which exists between the two rhomboids, from the figure in its present state, the absolute dimensions remaining unaltered. Let, therefore, the axis of the more obtuse rhomboid increase, till it equals that of the more acute one, without any alteration in the angles, and consequently in the parallelism of the edges of combination depending upon them. Whilst the axis increases, that part of the faces of the more obtuse rhomboid, which is visible in the combination, will become narrower and narrower, till it disappears, when the length of the axis is equal in both the forms. The planes of the more obtuse rhomboid are in this case tangent to the terminal edges of the more acute one, and the absolute dimensions are now in that state, in which they allow of a clear development of the relations between the forms which the combination contains.

6. Upright Position and Horizontal Projection.

Place a rhomboid in such a position that its axis is vertical. This is called the *upright position*. From the six angles of the rhomboid, B', C', ..., fig. 2. which are no apices, draw perpendicular lines B'O', C'R'...to a horizontal plane, and join the points in which these perpendiculars meet with the plane, by straight lines O'R', R'Z'...The regular hexagon H'O'R'Z'N'T' produced by those lines is called the *horizontal projection* of the rhomboid.

7. Relation of the Two Rhomboids expressed by the Side of the Horizontal Projection.

By comparing the planes of the horizontal projections HORZNT and H'O'R'Z'N'T' belonging to the rhomboids, we find that, the axes being supposed equal, the horizontal projection of the more obtuse is four times as large as that of the more acute, or it is to the same in the ratio of 4:1. From this follows the ratio of their sides = 2:1. Therefore, two rhomboids, the horizontal projections of which are in the ratio of 4:1, or the sides of these in that of 2:1, the axes being supposed equal, will be able to produce a combination in which the edges of combination are parallel to each other; also to the terminal edges of the more acute, and to the inclined diagonals (those which join the apex with the opposite angle of the faces) of the more obtuse rhomboids; provided the absolute dimensions allow the space to be limited by both the forms at the same time. This is one of the relations between simple forms, which are useful and necessary for explaining

the combinations, and of which the other relation *Mineralogy* will be explained in the following paragraphs.

8. Fundamental Form, Derivation, Derived Form.

What has been said above leads to a general method, one form being given or chosen, to find one or several others, which are in such relations to it, as to be fit for explaining the combinations. The form chosen for this purpose is called the *fundamental form* or *type*; the proceeding by which the other forms are produced the *derivation*, and those forms themselves the *derived forms*.

9. Relation of the Two Rhomboids expressed by the Axis.

The easiest method of expressing the relation of the derived rhomboids to the fundamental form (§ 7) is not that by the sides of the horizontal projections, the axes being supposed equal. Let, therefore, the derived rhomboid, without any alteration in its angles, diminish in size (as could be done by sections parallel to its faces) till its horizontal projection becomes equal to the horizontal projection of the fundamental form; its axis will decrease to half of its former length. Now, the horizontal projections being supposed equal, the axis of the derived rhomboid will be to the axis of the fundamental form in the ratio of $\frac{1}{2} : 1 = 1 : 2$, an expression of the relation between the two forms, which, on account of its easy application, we shall retain and make use of as we proceed.

10. Inversion of the Proceeding.

The mode of proceeding, by which the more obtuse rhomboid has been derived from the more acute one, can easily be inverted; setting out from the more obtuse one, we can, by the same way, in an opposite direction, derive the more acute rhomboid. The diagonals being drawn upon the faces of the rhomboid, and by planes laid through three and three of them, those parts which are situated on their outside being taken away, what remains will be a rhomboid more acute than the fundamental form. The axes of both these forms are equal, whilst the sides of the horizontal projections in the fundamental and the derived rhomboid are in the ratio of $1 : \frac{1}{2}$. Now, the horizontal projections being equal, the ratio of the axes will be $= 1 : 2$.

11. Generality of the Relations.—Series.

These modes of proceeding, and the relations between the derived forms, are general. If, therefore, from one rhomboid, taken for the fundamental form, another more obtuse has been derived, this same more obtuse rhomboid, considered as a fundamental form, will yield another still more obtuse; and if, on the other hand, from the fundamental form a more acute rhomboid has been derived, the same proceeding applied to the resultant form will give another still more acute; and this may be continued on either side *ad infinitum*. The ratio between the axes of any two subsequent rhomboids, the horizontal projections being supposed equal, has everywhere the same exponent. The axes are therefore in a geometrical progression, and the rhomboids repre-

Mineralogy. sented by these axes are themselves said to form such a progression or a series.

12. Laws of Progression of the Series.

Let A be the fundamental form, its axis $=a$. Let B represent the first, C the second more obtuse; B' the first, C' the second more acute rhomboid, the rhomboids will follow each other thus:

$$\dots C, B, A, B', C' \dots$$

their axes will be

$$a, 2a, 4a$$

or they are in the ratios of

$$4, \frac{1}{2}, 1, 2, 4 \dots$$

$$\dots 2^{-2}, 2^{-1}, 2^0, 2^1, 2^2 \dots$$

equal to those of the powers of the number 2.

The more obtuse rhomboids B, C... and the more acute ones, B', C'... derived from a given or supposed fundamental form A, their horizontal projections being equal, produce a series, in which the axes of the subsequent members increase on one side, and decrease on the other, like the powers of the number 2.

13. Designation.

The method of designating crystallizations, whether simple or compound, is founded on the present and similar series, to be developed afterwards. Represent the fundamental form by any arbitrary letter, in this case, according to the practice hitherto observed, by R. The sign of any other member of the series contains the same letter; the exponent of the fundamental number of the series, which, in the present case, is the number 2, being added for the sake of expressing the place occupied in the series by the number to be designated. This yields the crystallographic sign for one member, and by applying the same proceeding to the others, the designation also of the whole series.

14. Continuation.

The above mentioned part of the series of rhomboids is

$$C, B, A, B', C';$$

the ratio of their axes

$$2^{-2}, 2^{-1}, 2^0, 2^1, 2^2;$$

its designation, therefore,

$$R-2, R-1, R, R+1, R+2,$$

and in the same way $R+n$, the general term for each member of the series, which may be transformed into a particular one, by putting whole numbers, positive or negative, instead of n in the expression.

15. Usefulness of the Designation.

From the ratio of the axis to the side of the horizontal projection being known in a rhomboid, all the rest of its ratios, its dimensions (plain and solid angled), &c. can be deduced. The side of the horizontal projection is supposed equal in all the members of the series, and made $=1$ in the calculations

Mineralogy. which refer to the rhomboid. The designation contains therefore, by representing the relation of the axes, every thing required as a basis of calculation; and since it does not require any figures (for instance those of a fundamental form), the letter R signifying by itself a rhomboid, the designation is also evident, and upon this depends the easiness of its application in crystallography.

16. Limits of the Series.

There can be no doubt of n being able to obtain any possible value; or, which is the same, the series may be continued as far as we choose. This produces always new rhomboids, as long as n has a finite value. On one side the axes will increase, if n increase and remain positive; on the other the axes will decrease, if the negative value of n increases. Let n become infinite, the axis will likewise be infinite; let $-n$ become infinite, the axis will be infinitely small. It is clear that the limits of the series will be, on one side, a rhomboid of an infinitely large axis, on the other a rhomboid of an infinitely small axis, and their several signs must therefore be $R+\infty$ and $R-\infty$; so that

$$R-\infty \dots R+n \dots R+\infty$$

represent the series between its limits.

17. The Limits are Regular Six-sided Prisms.

It is very easily shown that a rhomboid of an infinite axis is a regular six-sided prism; for at the same time, as the axis increases, the six faces of the rhomboid approach nearer and nearer to parallelism with the axis, and they become really parallel with it, if the axis becomes infinitely long. For rendering more evident in what manner the regular six-sided prism is the limit of the series of rhomboids, we can imagine each face of the rhomboid to make a revolution round an immoveable line QS, fig. 3. This line is the side of that regular hexagon, which can be inscribed into the horizontal projection HORIZNT; the hexagon itself will be the basis or transverse section of the prism, and it differs from the horizontal projection by both its contents and its situation. If the axis of the rhomboid decrease till it ultimately evanesce, the faces contiguous not only to one, but also those contiguous to the other apex, coincide in one plane; and the rhomboid is changed into a plane figure, equal and similar to the horizontal projection, to which it is parallel, and appears, therefore, in all the combinations as a face perpendicular to the axis. It must here be remarked, that forms of infinite dimensions cannot be produced by themselves, or as simple forms, but appear only in combinations.

18. Position.

The series of rhomboids, already described, contains every thing concerning the dimensions and the ratios of its members, as far as each of them is considered singly or by itself. But there is still one object of great importance to be noticed, if those members are considered connected together, or in combinations. This is their position. It is evident that two subsequent members of the series, as, for instance, R and $R+1$, or, in general terms, $R+n$ and $R+n+1$, will produce the above combination

Mineralogy. in which the edges of combination are parallel, not only with each other, but also with the terminal edges of the more acute, and with the inclined diagonals of the more obtuse rhomboids; but they will produce this combination only in the case of their being in such a position, that the terminal edges of the one are in the same plane with the inclined diagonals of the other, which plane passes at the same time through the axis, as is shown by fig. 2, Plate XCVIII. This position of two rhomboids is termed the *turned position*, because it arises when a rhomboid is turned out of its former position, under an angle of 60° or 180° . If a rhomboid, in the turned position, undergo a new revolution of 60° or 180° , it returns to that which it occupied before, and this is called the *parallel position*. Rhomboids that affect a parallel position with each other, have their terminal edges and their inclined diagonals distributed in such a manner, that the terminal edges of both, on one side, and the inclined diagonals of both, on the other, fall into one and the same plane, passing through the axis.

19. Position of the Members in respect to each other.

The position of the fundamental form R is considered as the *normal position*, to which those of the derived members are referred. In reference to R, $R+1$ and $R-1$ will be in a turned, $R+2$ and $R-2$ in a parallel, $R+3$ and $R-3$ in a turned position again, and so on; from which it follows, that any two subsequent, or, in general, any two members of the series, between which an even number of members (0 in the above case being considered as even) are wanting, will be in the turned position, whilst any two members of the series, between which an odd number of members are wanting, will affect the parallel position. All those members, therefore, which have their exponent an even number, are in the parallel, those which have their exponent an odd number, in the turned position, if compared with R, the fundamental form of the series. The position exercises no influence upon the regular six-sided prism, since, by turning it under angles of 60° and 180° , its faces will come into their former situation.

20. Scalene Six-sided Pyramids.

The rhomboid allows several forms to be derived from it, which are not themselves rhomboids like the original. Lengthen the axis of a rhomboid, fig. 4, Plate XCVIII, on both sides to an indefinite but equal distance, and from the angles B, C, ... draw straight lines to the terminal points A', X', of the lengthened axis. The planes which can be laid through any two contiguous lines of these, and the lateral edges, BC, CB, ... of the rhomboid will produce a form, which, from its faces being scalene triangles, is called a *scalene six-sided pyramid*. The solid angles, A', X', at the terminal points of the axis, are its *apices*; the edges which terminate in these apices are the *terminal*, and those which correspond with the lateral edges of the rhomboid are the *rhomboidal edges* of the pyramid. The terminal edges allow of a farther distinction into *more obtuse* and *more acute* ones; the faces being on AB, the first, inclined under a greater, on AC the other, under a less angle.

21. Their Axis a Multiple of the Axis of the Fundamental Form.

Instead of lengthening the axis, we may conceive it to be multiplied by a certain number, expressed in general by m . The values of m must be determined by observation, or, which is the same, they must be derived from combinations containing six-sided pyramids. They cannot, therefore, be fixed arbitrarily, if we expect them to be confirmed by observation.

22. Series of Scalene Six-sided Pyramids.

From each rhomboid, several scalene six-sided pyramids may be derived, and we are authorized to expect as many forms of this kind as observation has discovered different values for m . By deriving scalene six-sided pyramids, according to a constant m , from the subsequent members of the series of rhomboids, a *series of such pyramids* is produced, the axes of which partake of the law followed by those of the series of rhomboids. For the horizontal projections of the pyramids are identical with those of the rhomboids, because the rhomboidal edges of the pyramids have the same situation as the lateral edges of the rhomboids from which they are derived; and the axes of the pyramids, being equal to the axes of the rhomboids, multiplied by a constant number m , will therefore persist in the ratio of those.

23. Designation.

The letter P, in general, signifies a pyramid, but more particularly a six-sided pyramid, if referred to a form derivable from the rhomboid. The quality of a scalene six-sided pyramid, in which there occur differences according to the relation of its axis to that of the rhomboid, must be made evident by the designation. Include the general sign for the pyramid, expressed in such a manner as to refer to the rhomboid from which it is derived, within crochets (), and add the number of derivation, or that by which the axis of the rhomboid has been multiplied, in order to produce the axis of the pyramid, in the form of an exponent; the result will be the crystallographic sign of a scalene six-sided pyramid. Thus $(P+1)^2$ represents a scalene six-sided pyramid derived from $R+1$ by multiplying its axis by the number 3; and $(P+n)^m$ is the general term of any or of each series of scalene six-sided pyramids, which can be derived from a series of rhomboids having R for its fundamental form, according to the value of m , determined for each particular series. If the axis of the rhomboid from which a scalene six-sided pyramid is derived, and the number of derivation m are known, the dimensions of the pyramid are easily to be found; thus every thing that has been said above (§ 15.) in respect to the designation, can be equally applied in the present case.

24. Values of m .

Although the value of m be, as far as experience goes, most commonly = 2, 3, or 5, yet it sometimes affects others, and even fractionary numbers. The only thing to be said in general of the value of m is, that it must be greater than 1, rational and positive.

Every series leads to its limits; it is, therefore, to be expected, that the series of scalene six-sided pyramids will have limits of their own. It appears by an easy geometrical construction, that scalene six-sided pyramids, derived according to a constant m , from the different members of a series of rhomboids, or even from any rhomboid though it be no member of that series, if cut perpendicularly upon, and through the centre of their axes; that such pyramids will have a common, or equal and similar transverse section, provided only the horizontal projections of these rhomboids have been equal. This section is an equilateral dodecagon of alternately equal angles. The limits of a series of scalene six-sided pyramids must therefore be a scalene six-sided pyramid of an infinite axis; which, since m cannot become infinite, must be deriveable from a rhomboid of an infinite axis, that is to say, from a regular six-sided prism. The limit will, therefore, appear in the shape of an *unequiangular twelve-sided prism*, of the same transverse section, which the finite members of the series produce. Each series of scalene six-sided pyramids is limited by a prism of this kind; the number of different prisms will therefore be equal to the values of m , upon which the angles of their transverse sections depend. The opposite limit, viz. the scalene six-sided pyramid of an infinitely small axis again appears in a plane figure, equal and similar to the horizontal projection, its faces being perpendicular to the axis of those forms with which it is combined. The general sign of an *unequiangular twelve-sided prism* is $(P+\infty)^m$. The face perpendicular to the axis does not require any particular designation, since that of $R-\infty$ (§ 15) is already applied to it. Respecting the position, both of the scalene six-sided pyramids, and of their limits, the *unequiangular twelve-sided prisms* to each other, and to the rhomboidal form from which they are derived; §§ 18 and 19 contain the necessary explanations.

26. Subordinate Series of Rhomboids.

There are several rhomboids in connection with R , without being members of the series derived from it, because their axes, the horizontal projections being equal, are not products of the axis of R , multiplied by powers of the number 2. These rhomboids follow, however, the law (§ 12) which governs the series of rhomboids immediately derived from R , and their axes are results of the axes of the members of this series multiplied by a certain coefficient. Series arising in this way are termed *subordinate series*, whilst that which has been derived from R has the relative name of the *principal series*.

27. Coefficients of the Subordinate Series, and how the Members of these bearing to each other and to the Members of the Principal Series.

Members of the subordinate series are geometrically obtained by laying planes into the homologous terminal edges of the scalene six-sided pyramids derived from the members of the principal series, and by enlarging these planes till they inclose the

space by themselves. By applying the planes to the more obtuse terminal edges, the resulting coefficient

is $= \frac{3m+1}{4}$; by applying them to the more acute

ones, it follows $= \frac{3m-1}{4}$. If the three most com-

mon values of m are one after the other put into the expressions, each of the two coefficients give rise to members of two different subordinate series; but at the same time it yields one member of the principal

series, namely, if $3m+1$ becomes equal to a power of the number 2. These numbers of the principal series are not, however, objects of the present consideration. The subordinate series, whose coefficient contains, besides a power of the number 2, the number 5, is styled the *first*; that whose coefficient, also besides a power of the number 2, contains the number 7, the *second* subordinate series. The members of the subordinate series arrange themselves with those of the principal series in such a manner, that the axes of those which are put together stand in the ratio of $1 : \frac{5}{4} : \frac{7}{4}$. According to this disposition, a rhomboid, whose axis contains five-fourths of the axis of $R+n$, or which is $= \frac{5}{4} \cdot 2^n a$, its horizontal projection being equal to that of R , is $R+n$ of the first subordinate series, and its designation is $\frac{5}{4} R+n$, a rhomboid whose axis is $= \frac{7}{4} \cdot 2^n a$, is $R+n$ of the second subordinate series, and its designation is $\frac{7}{4} R+n$. Any other value of m affords other subordinate series. The members of a subordinate series cannot be interpolated, or put between those of the principal one, without undoing both these series themselves. The limits of the subordinate series are identical with those of the principal series; the position of their members follows from their derivation.

28. Isosceles Six-sided Pyramids.

Apply pairs of planes to the terminal edges AC , of a rhomboid, fig. 5, Plate XCVIII., in such a manner and inclination, that those from the upper apex, AHO and AOR , may intersect those from the under apex, XHO and XOR , in a plane figure $HORZNT$, similar to and parallel with the horizontal projection. The result will be an *isosceles six-sided pyramid*. The axes of both the pyramid and the rhomboid being equal, as appears from the derivation, the sides of their horizontal projections are in the ratio of 3 : 2. Hence the horizontal projections being supposed equal, the ratio between the axis of the pyramid and that of the rhomboid will follow $= 2 : 3$, or the first will contain $\frac{2}{3}$ of the axis of that rhomboid from which it is derived. The isosceles six-sided pyramid, derived from $R+n$, is designated only by $P+n$ (§ 23), on account of its being always obtained by a similar proceeding from its rhomboid.

29. Series of Isosceles Six-sided Pyramids.

Each member of the principal series of rhomboids has its concomitant isosceles six-sided pyramid of the ratio just stated, the horizontal projections being equal. This gives rise to a series of isosceles six-sided pyramids, the axes of which, their horizon-

Mineralogy. tal projections being equal, increase and decrease as the powers of the number 2; that is to say, they follow the general law of all those forms which are derived from the rhomboid.

30. Limits and Position.

The limits of this series are regular six-sided prisms of infinite axes, like those of the series of rhomboids. Let the axis of an isosceles six-sided pyramid increase, whilst the horizontal projection remains unchanged, the inclination of the faces at the edges of the basis (those in which the faces from different apices meet) will likewise increase till it becomes $=180^\circ$, in which case the axis will be infinite. In this case, each two corresponding faces from the different apices coincide into a single plane parallel with the axis, and the isosceles six-sided pyramid is thus transformed into a regular six-sided prism, the basis or transverse section of which is the horizontal projection itself. By this basis and its situation the present prism differs from that (§ 17), which limits the series of rhomboids; and by this the necessity of considering them as two distinct forms becomes evident. The crystallographic sign for the limit of the series of isosceles six-sided pyramids is $P + \infty$. The opposite limit, merely a face perpendicular to the axis of any of the foregoing forms, requires no particular designation. Since the faces of an isosceles six-sided pyramid, when this is turned round under 60° or 180° , resume their former situation, there is no difference prevailing in the position of the members and limits of this series, either in respect to themselves, or to the other forms derived from the rhomboid.

31. Derivation from the Isosceles Four-sided Pyramid.

Consider an *isosceles four sided pyramid* (Plate XCVIII. fig. 6), a form contained under eight equal and similar isosceles triangles, as a fundamental form; place it in its upright position, by making its axis AX vertical, and apply to it the process § 5. The tangent planes will limit a space representing again an isosceles four-sided pyramid, the plane angles of which at the apex, and the inclination of the faces at the terminal edges, will be greater than the same in the fundamental form, and hence it will likewise be the more obtuse of both.

32. Ratio of the Derived Pyramid to the Fundamental Form.

The axes of these pyramids are equal to each other. The horizontal projection of the more obtuse is that square which can be circumscribed to the horizontal projection of the fundamental form; and, accordingly, its content twice the content of the horizontal projection of the fundamental form, the ratio of their sides $=\sqrt{2}:1$. Suppose now the horizontal projections of the two pyramids to be equal, the axis of the derived more obtuse pyramid will be to the axis of the fundamental form in the ratio of $\frac{1}{\sqrt{2}}:1$.

33. Inversion of the Proceeding.

Mineralogy.

This proceeding can be applied inversely, in order to obtain from the fundamental form the same more acute four-sided pyramid, from which, by the proceeding applied directly, the fundamental form would have been the result. This inverse application is as follows: Draw in the faces of the fundamental form perpendicular lines from the apices to the edges at the basis, lay cutting planes through every two contiguous of these lines, and separate those parts of the pyramids which lie outside of them. The remainder, inclosed by the cutting planes, will be again an isosceles four-sided pyramid, having the same axis as the fundamental form, but a horizontal projection, whose content is half the content of the horizontal projection of the fundamental form, and the ratio of their sides, therefore, $=\sqrt{\frac{1}{2}}:1$. The horizontal projections being made equal, the axis of the derived more acute pyramid is to the axis of the fundamental form in the ratio of $\sqrt{2}:1$, which is the inverse of the ratio deduced above.

34. Series and Designation.

By continuing the derivation, the more obtuse pyramid produces another still more obtuse; the more acute another still more acute, and thus arises a series of isosceles four-sided pyramids, whose axes, their horizontal projections being equal, increase and decrease as the powers of the square root of 2;

which law of progression can be expressed by $2^{\frac{n}{2}}$, or $\sqrt{2}^n$. The designation of this series is concordant with the principles already laid down and followed (§ 13). The fundamental form receives the letter P. Hence its neighbouring members will be

$$\dots P-2, P-1, P, P+1, P+2, \dots$$

their axes, that of P being $=a$,

$$\dots \frac{a}{2}, \frac{a}{\sqrt{2}}, a, a\sqrt{2}, 2a; \dots$$

their ratio to each other,

$$\dots \sqrt{2}^{-2} + : \sqrt{2}^{-1} : \sqrt{2}^0 : \sqrt{2}^1 : \sqrt{2}^2; \dots$$

and $P+n$ the general term of the series, which, by the substitution of any whole positive or negative number in the place of n , gives a certain determined member. The present designation is quite the same as that in § 28, and as another to be mentioned in § 44. However, the observation in page 431 is sufficient to show the impossibility of any confusion or ambiguity that could arise from making use of identical signs for the expression of different forms.

35. Limits.

If n becomes greater or smaller than any given number, a transformation takes place similar to that by which the isosceles six-sided pyramid gave rise to the regular six-sided prism: the series of isosceles four-sided pyramids terminates on one side in an unlimited four-sided prism, on the other in a plane figure, equal, similar, and parallel to the horizontal projection, and these two forms represent the limits of the series. In respect to the first, however, there

Mineralogy. occurs the particular circumstance, that the series is doubly limited; because the different members in their succession assume a different position. The derivation shows the pyramids, $P-1$ and $P+1$, to stand in such a position towards P , that the sides of their bases are parallel with the diagonals of the basis of P ; whilst, in $P-2$ and $P+2$, the sides and the diagonals are parallel with the same lines in the basis of the fundamental form. The former are said to be in a *diagonal*, the latter in a *parallel* position with P ; and every thing contained in § 18 and § 19, in respect to position, may be applied here, if only, instead of 60° and 180° , a revolution of 45° is imagined. Suppose now the two different prisms, the regular six-sided, as well as the rectangular four-sided, in both their peculiar positions. The faces of the first will, after having been duly turned, assume their former situation, which is not the case in the second; and hence it becomes necessary to adopt two rectangular four-sided prisms of an infinite axis as limits of the series of isosceles four-sided pyramids, one being in a parallel, the other in a diagonal position with P . The sign of the first is $P+\infty$, that of the second $[P+\infty]$. The opposite limit, where there is no difference in the position, is represented by $P-\infty$; and the whole series of isosceles four-sided pyramids between its limits appears thus,

$$P-\infty \quad . \quad P+n \dots \left\{ \begin{array}{l} P+\infty \\ [P+\infty] \end{array} \right\}$$

36. Scalene Eight-sided Pyramids.

With the isosceles four-sided pyramids there are connected *scalene eight-sided pyramids* contained under sixteen equal and similar scalene triangles (Plate XCVIII. fig. 7). These eight-sided pyramids depend upon the four-sided by the same process of derivation, by which the scalene six-sided pyramids take their rise from the rhomboid. The application of this process to the isosceles four-sided pyramid supposes, however, a preparation of this form, which is effected by enlarging its faces beyond the edges at its basis, and by drawing in these enlargements triangles, equal and similar to the faces of the pyramid. Thus, the points $a, a' \dots x, x \dots$ are fixed in two squares that are perpendicular to the axis AX , in its terminal points, or in the apices of the pyramids. Now, produce the axis of the pyramid on both sides to an indefinite but equal length, or multiply it by a number m , greater than 1 positive and rational (§ 24). Join, then, the upper terminal point A' of the lengthened axis with the points $a, a' \dots$ in the under, the under terminal point X' with the points $x, x' \dots$ in the upper square, by straight lines. The points $SS' \dots$, in which these lines intersect each other, will lie in the prolongation of the basis of the four-sided pyramid. We now join these points with the neighbouring angles of the base by straight lines, the result of which will represent the basis of the derived scalene eight-sided pyramid, which may now be completed without difficulty. The most common, though not the only values given for m by nature, are 3, 4, and 5.

37. Series of Scalene Eight-sided Pyramids.

If the number of derivation m be constant, the re-

sultant scalene eight-sided pyramids have similar bases, the axes of the isosceles four-sided pyramids may be whatever they will. The application of the described proceeding to the subsequent members of the series of isosceles four-sided pyramids will, therefore, remaining for all the members the same, not only produce a series of scalene eight-sided pyramids, subject to the law followed by the isosceles four-sided pyramids, which is that of $\sqrt{2}$; but the bases or transverse sections of all the members of this series will be similar to each other. The designation of an indeterminate n th member of such a series is $(P+n)^m$, and it is evident, that as many values of m as experience gives, so many different series of scalene eight-sided pyramids will arise.

38. Limits.

The limits of those series are, on one side unlimited unequiangular eight-sided prisms, the transverse sections of them being similar to the bases of the members of the series; on the other side a plane figure, which in the combinations appears as a face perpendicular to the axis. This is evident from what has been said above, and there remains only to be added, that the prisms of an infinite axis, coming into consideration in two different positions, they must be taken for two different forms, or as double limits of the series. These two positions are the *parallel* and the *diagonal*, as in § 35; the parallel being that which prevails between scalene eight-sided pyramids and that isosceles four-sided from which they are derived; whilst forms of this kind in the diagonal position are supposed to have undergone a horizontal revolution of 45° . Now the eight-sided prisms may be considered as scalene eight-sided pyramids, derived from isosceles four-sided pyramids of an infinite axis, namely, the rectangular four-sided prism, according to a certain value of m . The necessity of considering the four-sided prism in m two different positions (§ 35) must therefore be extended to the eight-sided. The designation of the series of eight-sided pyramids, between their limits, will accordingly be thus:

$$P-\infty \quad (P+n)^m \quad \left\{ \begin{array}{l} (P+\infty)^m \\ [(P+\infty)^m] \end{array} \right\}$$

39. Subordinate Series.

There are series of isosceles four-sided pyramids, belonging to that of § 33, which, in reference to the latter, or the *principal series*, are termed *subordinate series*. The members of these series are obtained by placing tangent planes in the homologous terminal edges of the scalene eight-sided pyramids; the same proceeding which applied to the scalene six-sided pyramids produced the subordinate series of rhomboids. The coefficient for the more obtuse terminal edge

(if $m \geq 1 + \sqrt{2}$) is $= \frac{m+1}{2}$; that for the more acute

one (under the same supposition) $= \frac{m}{\sqrt{2}}$. If m be determined, each of those coefficients gives a mem-

Mineralogy. ber of a particular series. The members of the principal and of the two subordinate series arising from m

$$= 3, 4, \text{ and } 5, \text{ arrange themselves thus : } 1 : \frac{3}{2\sqrt{2}} : \frac{5}{4};$$

and are said to belong together in this order. An isosceles four-sided pyramid, therefore, whose axis is a , the horizontal projection being equal to that of P , is

$$= \frac{3}{2\sqrt{2}} \sqrt{2}^n a \text{ represents the member } P+n \text{ of the}$$

first subordinate series, and bears the designation of $\frac{3}{2\sqrt{2}} P+n$; and a similar pyramid, the other circumstances remaining the same, with an axis $= \frac{5}{4} \sqrt{2}^n a$

is the member $P+n$ of the second subordinate series, expressed by the designation $\frac{5}{4} P+n$. The limits of

the present series coincide with those of the principal series. The positions of its members in respect to each other, and to the members of the principal series, will become evident, by comparing what has been stated of their derivation with § 27. regarding the position of the subordinate series of rhomboids.

40. Scalene Four-sided Pyramids.

If in the basis of an isosceles four-sided pyramid, the diagonals are supposed unequal, the pyramid itself is transformed into a *scalene four-sided pyramid*, or into one whose basis is a *rhomb*, its faces *scalene triangles*, and its terminal edges of a different magnitude, the one more obtuse the other more acute, as is represented by ABOBCX, fig. 8. From this we may conjecture that several of the preceding methods of derivation, though with some modifications, will also in this case be applicable.

41. Derivations from it. Auxiliary Form.

Apply to the *homologous* terminal edges of a scalene four-sided pyramid tangent planes, and enlarge them till they intersect each other in every possible direction; the result will be no form limited on every side, or such as is finite in all its dimensions. If the tangent planes are laid in *all* the terminal edges of the fundamental form, a form limited from every side will indeed appear, but this form is *not* a *simple* one, its faces being homologous only by four and four (§ 1). The form thus arising represents a four-sided pyramid, with an *oblong rectangular* basis, AFGHIX, fig. 8; and most of the crystallographers consider it as such, and term it accordingly. In this place it must be considered only as an *auxiliary* or *intermediate* form, which is not the derived form itself, but useful and auxiliary for its derivation.

42. Derived Form.

Suppose tangent planes to be laid in the terminal edges of the *auxiliary form*, in such an inclination that those from the upper apex produce by their intersection with those from the under apex a rhomb similar and parallel to the basis of the fundamental

form, and situated in the prolongation of this basis. Mineralogy. The result will be a *scalene four-sided pyramid*, the basis of which is similar to that of the fundamental form; but the plane angles at the apex, and the inclination at the terminal edges, being greater than in this form, the derived will be more obtuse than the fundamental form.

43. Ratio to the Fundamental Form.

The two pyramids, as produced by the derivation have the same axis, the ratio between the basis of the derived, and the basis of the fundamental pyramid being that of 4 : 1. This ratio is evident, since the basis of the auxiliary form is double of the basis of the fundamental form, and that of the derived form again double of the basis of the auxiliary form. Hence the horizontal projection of the two forms being supposed equal, the ratio between the axes of the derived and of the fundamental pyramid is that of $\frac{1}{2}$: 1. The process of derivation, by which the more obtuse pyramid is produced, is liable to an inversion like that in § 10.

44. Series. Designation. Limits. Position.

From a continued derivation on both sides of the fundamental form, a series of scalene four-sided pyramids, of equal and similar bases, will evidently arise, the axes of which increase on one side and decrease on the other, like the powers of the number 2. $P+n$ will be the sign of an indeterminate n th member of the series, and if n becomes infinite, the series reaches its limits, which are on one side an obliquangular four-sided prism, whose transverse section on the other side is a horizontal plane, whose figure is equal and similar to the horizontal projection of the fundamental form. The designation of the series between its limits becomes thus:

$$P-\infty \dots P+n \dots P+\infty.$$

It must be remarked, that such differences on account of the position of the members of the series as are met with in the rhomboid (§ 18) and the isosceles four-sided pyramid (§ 35), are not to be found in the scalene four-sided pyramid.

45. Further Derivations.

The members of the present series are, or this series itself is, now the foundation of several other derivations; and although the forms derived by them will be nothing but scalene four-sided pyramids and obliquangular four-sided prisms, yet the variety in the relations of those forms is great enough to surpass that of the forms in connection with the rhomboid, and with the isosceles four-sided pyramid, for which reason it is one of the most interesting objects of crystallography. The derivations already mentioned apply as well to the fundamental form itself as to the auxiliary form; and they are similar to that which has been employed in deriving the scalene eight-sided from the isosceles four-sided pyramid.

46. From the Fundamental Form.

Instead of the isosceles (§ 37), suppose the scalene

Mineralogy. four-sided pyramid to be the fundamental form, and prepare it for derivation by enlarging its planes beyond the edges at the basis, and by drawing triangles equal and similar to the faces of the pyramid in these enlargements. The points a, a', x, x', \dots will no longer be the angles of squares, but of oblong rectangles, the planes of which are perpendicular to the axis AX in its terminal points. Produce now the axis of the scalene four-sided pyramid on both sides to an indefinite, but equal length, or, what comes to the same, multiply it by a number m , enjoying the general properties mentioned, §§ 24, 26. Draw straight lines from the points a, a', \dots in the lower rectangle to the upper apex A', from the points x, x', \dots in the upper rectangle to the under apex X' of the lengthened axis, and join their intersections s, s', \dots in the plane of the enlarged basis by straight lines with the angles of this basis. The resultant octagon will not have alternately equal angles, like that in § 36, which is the basis of the scalene eight-sided pyramids, but it will be irregular, fig. 9, since of the angles B, B', c, c', only the opposite are equal to each other. A form constructed upon such a basis cannot be contained under equal and similar planes, or it cannot be a simple form. Like the four-sided pyramid of an oblong rectangular basis, it is considered as an auxiliary or intermediate form, whose resolution gives the simple forms of which it consists.

47. Resolution of the Auxiliary Form.

This resolution is executed by enlarging those places which are equal and similar to each other, till the rest disappear. In the present case, the resolution produces two different scalene four-sided pyramids of equal axes, their bases being different amongst themselves, as well as from the bases of the fundamental form. They are termed *scalene four-sided pyramids of dissimilar bases, derived from the fundamental form*, and more particularly that in which the long diagonal of the fundamental form remains unaltered, the pyramid belonging to the long: that in which the short diagonal remains unaltered, the pyramid belonging to the short diagonal of the fundamental form.

48. Designation.

This important difference between the two forms must be expressed by the designation. The designation $(P+n)^m$ used for the scalene eight-sided pyramids in § 37, if referred to forms in connexion with the scalene four-sided pyramids, denotes at the same time both of the pyramids just mentioned. In order to make it applicable to each of them singly, it is now necessary to express their difference in respect to the diagonals of the fundamental forms, which is effected by adding the signs + and -. Thus $(P+n)^m$ represents a scalene four-sided pyramid of dissimilar basis, derived from P+n according to the number m , which belongs to the long diagonal; $(\bar{P}+n)^m$, another pyramid of the same properties which belongs to the short diagonal of P.

49. Ratios.

The pyramids just mentioned differ from the mem-

bers of the series (§ 44), 1st, in their axes, which, the Mineralogy. axis of P being $=a$, are expressed by $2^m a$; 2d, by the ratio of the diagonals of their bases. Let in P the ratio of the axis to the long and to the short diagonal be that of $a:b:c$, or the ratios of the same lines in P+n that of $2^m a:b:c$; the ratio of the homologous lines will be

$$\text{in } (\bar{P}+n)^m = 2^m ma : b : mc,$$

$$\text{in } (\bar{P}+n)^m = 2^m ma : mb : c,$$

as follows easily from the consideration of a few triangles in the figures required for explaining the derivation. Hence the ratio between the diagonals of the bases in the derived forms, that of the fundamental form remaining constant, depends only upon the number m . Accordingly, if m be supposed constant, all the pyramids of this kind, derived from scalene four-sided pyramids of similar bases, will likewise, as far as they belong to one or the other diagonal, contain similar bases or transverse sections, the axes of the forms, subservient to the derivation, may be whatever they will.

50. Double Series.

If those forms are the members of the above series, each m gives rise to two series of derived pyramids of a dissimilar basis, viz. one whose members refer to the long, and another whose members refer to the short diagonal of the basis of the fundamental form. From each of those series having constant transverse sections in all their members, it appears that the obliquangular four-sided prisms, limiting them, must likewise be subject to the equality of transverse sections or bases. Both the series stand, therefore, between their limits, thus:

$$P-\infty \dots (\bar{P}+n)^m \dots (\bar{P}+\infty)^m$$

$$P-\infty \dots (\bar{P}+n)^m \dots (P+\infty)^m$$

What has been observed in § 44 in respect to position, may be equally applied here. The values of m hitherto most commonly, though not exclusively observed, are $= 3, 4, 5$. But neither in this case are they the only ones.

*

51. Derivations from the Auxiliary Form, § 41. Ratios of the Series.

Instead of the fundamental form P, or of P+n, suppose the auxiliary or intermediate form, belonging to it, to take its place; by applying to it the proceeding described in §§ 46, 47, the form produced is a compound one like that in § 46, but its resolution yields again two simple forms, which are also scalene four-sided pyramids, whose bases are dissimilar to those of the fundamental form. These pyramids can be distinguished from each other by referring, the one to the long, the other to the short diagonal; from those derived in § 47, by the form to which the derivation is applied, since, in § 47, it is the fundamental form itself, in the present case, the auxiliary form belonging to it; which latter circumstance is expressed in the crystallographic sign by the letter

Mineralogy. r added to P . From the dimensions of the three lines disposed perpendicularly to each other in the pyramid $P+n$, the axis and both the diagonals, being in the ratio of $2^n a : b : c$, it will follow, the ratio of the homologous lines in the scalene four-sided pyramids of dissimilar basis, derived from the auxiliary form, which belongs to the long diagonal of the fundamental form, or in

$$(Pr+n)^m \text{ to be } = \left(\frac{m+1}{2}\right) \cdot 2^n a : b : \left(\frac{m+1}{m-1}\right) c,$$

$$\text{in } (Pr+n)^m : \left(\frac{m+1}{2}\right) \cdot 2^n a : \left(\frac{m+1}{m-1}\right) b :$$

The dependence of the ratios between the diagonals of the basis, only from m , is evident; and this remains unaltered, how much soever a and n may be allowed to vary. If the derivation is applied to the whole series in § 44, there will arise two series of scalene four-sided pyramids, which proceed according to the law of the fundamental series, and are limited by obliquangular four-sided prisms, partaking of the similarity in the transverse sections of all the members. The crystallographic designation of the series, between their limits, stands thus:

$$P-\infty \dots (Pr+n)^m \dots (Pr+\infty)^m$$

$$P-\infty \dots (Pr+n)^m \dots (Pr+\infty)^m$$

The values of m are here the same as in the above mentioned cases. To the position applies what has been said in § 44.

52. Subordinate Series.

That there are certain subordinate series belonging to the series § 44, which, in reference to the former, may also be considered as the principal series, can easily be supposed from the agreement existing between the forms derived from the scalene and those derived from the isosceles four-sided pyramid. In order to obtain the members of these subordinate series, enlarge the faces of the fundamental form, fig. 10, Plate XCVIII., on both sides; draw in the enlarged faces triangles, equal and similar to the faces of the fundamental form; through the point $a, a' \dots x, x' \dots$, thus determined, lay rhombs, similar and parallel to the basis of the fundamental form; multiply the axis by a number m ; join the points X', A' , of the lengthened axis by straight lines with the said points $a, a' \dots x, x'$; and, lastly, reduce the derived pyramid which has a basis similar to that of the fundamental form, to an equal horizontal projection with it. The number m being not yet determined, the coefficient of the subordinate series will be $= \frac{m+1}{2}$; which, if $m+1$ be equal to any power

of the number 2, shows the member to which it belongs to be a member of the principal series. The subordinate series, whose coefficient, besides powers of the number 2, contains the factor 3, is termed the first, and that which, in the same case, contains the factor 5, the second subordinate series. Members of the principal, of the first and of the second subordinate series, which are supposed to belong together, arrange themselves thus: $1 : \frac{3}{2} : \frac{5}{2}$, which numbers

express the ratio between their axes. The designation and the position of the members in the subordinate series is evident from the foregoing.

53. Resolution of the Auxiliary Form, § 41. Horizontal Prisms.

The only form now left for examination is the auxiliary form, § 41; which, as has been mentioned above, is not a simple one, its faces not being homologous. By enlarging only those planes which, amongst themselves, are equal and similar, there arise two obliquangular four-sided prisms, unlimited in the direction of their axis, and which, therefore, like all the prisms, are forms in which one dimension is infinite. The axes of the two prisms are perpendicular to each other, and have a horizontal position, if the fundamental form be in the upright position. These axes coincide with the diagonals of the basis of the fundamental form produced to an infinite length. Hence the prisms may be considered as scalene four-sided pyramids, one diagonal of which has become infinite; similarly to the vertical prisms, that are scalene four-sided pyramids of an infinite axis. For the sake of distinguishing them from these, they bear the name of horizontal prisms, and their general designation is $Pr+n$. More particularly, $Pr+n$ expresses the horizontal prism in which the longer diagonal, $Pr+\infty$ that in which the shorter diagonal of the fundamental form has remained a finite quantity.

54. Series of Horizontal Prisms.

Every scalene four-sided pyramid, whatever its properties may be, has its dependent horizontal prisms. To every series of such forms will, therefore, belong two series of horizontal prisms, to be distinguished by their designation according to the properties of those series. It is, however, remarked, that if we take the common values of m , as stated above, the angles of several members of those series, and, therefore, the series themselves, will be identical; and for this reason, one designation will suffice for them. Thus, the number of series of those forms taken together may be reduced to three pairs, of which the first pair belongs to the principal, the others to the subordinate series of scalene four-sided pyramids; each of the diagonals having one series referred to it. The horizontal prisms belonging to a scalene four-sided pyramid are produced, by placing tangent planes in its homologous terminal edges. If those terminal edges connect the terminal point of the axis with the long diagonal, the prism is said to belong, or to be referred, to the long; if they connect it with the short, it is said to belong, or to be referred, to the short diagonal of P . The horizontal prisms are remarkable forms, often to be met with in the natural combinations.

55. Limits of the Series of Horizontal Prisms.

By comparing the horizontal prisms belonging to members of a series of scalene four-sided pyramids it becomes evident how, whilst the axis of the pyramid increases, the angle of the horizon-

Mineralogy. tal prism contiguous to the axis of the fundamental form becomes smaller and smaller; whilst the other, at the intersection of the planes from different apices, becomes greater and greater. If the axis of the pyramid become infinite, or the pyramid itself a vertical prism, the first of these angles will disappear, the second become $= 180^\circ$. Hence a horizontal prism is transformed, in this case, in a pair of unlimited parallel planes, perpendicular to the diagonals to which they belong. These planes, which may be considered as forms unlimited, as it were, in two directions, are the limits of the series of horizontal prisms, the axis of the pyramid to which they belong being infinite. The opposite limits, or those which appear, if the pyramid have an infinitely small axis, appear as faces perpendicular to the axis. The series of horizontal prisms between their limits may, accordingly, be represented thus:

$$P-\infty \dots Pr+n \dots Pr+\infty$$

$$P-\infty \dots Pr+n \dots Pr+\infty.$$

For having the designation in every respect complete, the coefficient of the series to which the horizontal prism belongs must be added to the sign for a particular member.

Although this is not a place for entering into the examination of combined forms, yet that peculiar combination which is produced by the two limits of the series of horizontal prisms, and takes the appearance of a vertical rectangular four-sided prism, not yet limited in the direction of its axis, cannot remain unnoticed. This combination is designated by $Pr+\infty \cdot Pr+\infty$; it must carefully be distinguished from the rectangular four-sided prisms, limiting the series of isosceles four-sided pyramids, which, abstraction being made of the face perpendicular to the axis, are simple forms; a property not belonging to the rectangular prism in connection with the scalene four-sided pyramid.

56. Derivations from the Hexahedron.

Besides the rhomboid, the isosceles and the scalene four-sided pyramids, there is only one other form existing fit for being considered as a fundamental form, or which, without being derivable from any one of the former, can itself serve as basis to the derivation. This form is the *hexahedron*, Plate XCIX. fig. 11. There are, in connection with the hexahedron, a great number of other forms, remarkable for their properties, differing, however, from each other more by their general aspect than by their dimensions. The complete assemblage of those forms is obtained in the following way. Bring first the hexahedron in an upright position, so as to bring one of its corners uppermost, and the opposite perpendicularly below it, by which means the rhomboidal axis, passing the two corners, becomes vertical; then consider the possible situations of a moveable plane, tangent to the hexahedron in the uppermost point of the said rhomboidal axis. The different situations the plane can effect are seven in number; but in one of them it becomes parallel to the face of the hexahedron itself. Every one of these situations gives rise to a peculiar form; hence there will exist as many forms as the moveable

plane can assume different situations, and no more. Mineralogy. The forms thus obtained agree in several of their properties, particularly in respect of the kind, number, and situation of their axis, and are as follows: 1. The *hexahedron*, contained under six squares. 2. The *octahedron*, fig. 12, contained under eight equilateral triangles. 3. The *two-edged tetragonal dodecahedron* (fig. 13), contained under twelve rhombs. 4. The *hexahedral trigonal-icositetrahedron* (fig. 14), contained under twenty-four isosceles triangles, its prominent form being that of the hexahedron. 5. The *octahedral trigonal-icositetrahedron* (fig. 15), contained under twenty-four isosceles triangles, its prominent form being that of the octahedron. 6. The *two-edged tetragonal-icositetrahedron* (fig. 16), contained under twenty-four irregular tetragons, in which two of the opposite angles are equal; and 7. The *tetracontaoctahedron* (fig. 17), contained under forty-eight scalene triangles. The dimensions of the three first of these forms are constant, a property not to be met with in the others, of which, therefore, several varieties may be found differing from each other by their angles.

57. Resolution of some of those Forms into Halves.

This assemblage, though it is complete, seems not to contain all the forms in connection with the hexahedron, as they are produced by nature, such as, for instance, the tetrahedron, the pentagonal dodecahedron, &c. Nevertheless it contains them; for they arise from a particular resolution of some of those mentioned in § 56. This resolution is effected by enlarging half of the number of planes to be met with in the form to be resolved, according to certain rules, and by making the rest of them disappear. The two forms which arise out of the resolution of one of the former are termed halves (not half forms, as the simple four, six, or eight-sided pyramids), and can be easily distinguished by the lesser number of their axis, as some of those that are common to the original forms disappear by the resolution. The two halves are perfectly equal and similar to each other; they differ, however, amongst themselves by that position in which they are placed by the resolution. The position of one of the halves being considered as the *direct*, that of the other will be the *inverse*. The latter is changed into the former, by inverting the vertical rhomboidal axis of the form, so as to bring the upper apex lowermost, and vice versa. Thus the halves, produced from octahedron, are the two *tetrahedrons* (fig. 18, Plate XCIX.), contained under four equilateral triangles; those from the hexahedral trigonal-icositetrahedron, the two *hexahedral pentagonal dodecahedrons* (fig. 19), contained under twelve irregular pentagons, which have two pairs of equal angles; those from the octahedral trigonal-icositetrahedron, the two *two-edged tetragonal dodecahedrons* (fig. 20), contained under twelve tetragonal faces, in which there is only one pair of equal angles; those from the two-edged tetragonal-icositetrahedron, the two *trigonal dodecahedrons* (fig. 21), contained under twelve isosceles triangles; and lastly, the halves of the tetracontaoctahedron, viz. a, the *tetrahedral trigonal-icositetrahedrons* (fig. 22), contained under twenty-four scalene

Mineralogy. triangles; *b*, the *three-edged tetragonal-icositetrahedrons* (fig. 23), contained under twenty-four irregular tetragonal faces, in which there are not two equal angles; and *c*, the *pentagonal-icositetrahedrons* (fig. 24), contained under twenty-four irregular pentagons, whose angles are all different.

58. *Resolution of some of the Halves into Fourths.*

The three last, or those halves which are obtained from the tetracontaoctahedron, allow of a further dissolution into halves of the halves, or into fourths. These are the *tetrahedral pentagonal-dodecahedrons* (fig. 25), contained under twelve irregular pentagons, in which there are not two equal angles. The difference between *right* and *left*, to be met with in this form, and in the *pentagonal-icositetrahedron*, deserves some attention. If two-fourths are combined in the same position, which they assume in the resolution, the halves are produced; and if the halves, produced by this combination, are combined likewise in their proper position, they will reproduce the original form, out of which the halves as well as the fourths have been obtained by way of resolution. Most of the original forms and their halves are already known in several varieties of minerals; some of the latter, viz. the *tetrahedral pentagonal-dodecahedrons*, and the *pentagonal-icositetrahedrons*, have not yet been found.

59. *System of Crystallization and Series of Crystallization.*

If only the *kind* of the fundamental form has been considered, the assemblage of the forms derived from it is called a *system of crystallization*; but if also notice has been taken of its dimensions, the assemblage of the derived forms receives the denomination of a *series of crystallization*. These two notions are of the same kind, and differ only by the number of objects they contain, the latter being a particular determination of the former; and both refer not so much to the mere aggregation of forms, as to the relations prevailing amongst them.

60. *Denomination of the Systems of Crystallization.*

The systems of crystallization, agreeing in number with the fundamental forms, of which there are four, receive their names according to those fundamental forms. That which has been derived from the rhomboid is called the *rhomboidal system*, because its forms agree with the rhomboid in their general properties; that which has been derived from the isosceles four-sided pyramid, for the same reason, the *pyramidal system*; that which has been derived from the scalene four-sided pyramid, the *prismatic system*, on account of the great number and variety of prisms it contains; and that which has been derived from the hexahedron, the *tessular system*, in order to intimate that there occurs no other system of crystallization in nature which shares in the general properties of the hexahedron. It is evident that any form, if known, will suffice for the determination of the system to which it belongs, even though this form be a limiting one. Only the right rectangular four-sided prism is an exception, since it may be a simple form in the tessular, a double combination

($P-\infty . P+\infty$) in the pyramidal, and a triple combination ($P-\infty . Pr+\infty . Pr+\infty$) in the prismatic system. The consideration of the mere form does not decide at all in this case. Some of the means of removing this uncertainty will be explained hereafter.

61. *Determination of the Series of Crystallization.*

A series of crystallization is determined by any one of its members, which is no limiting form, if the dimensions of it are known. These dimensions, if they are not (like those of the hexahedron, the octahedron, &c.) constant, must be made out by direct measurement. From these the dimensions of any other member, or of the fundamental form, if it has not been measured itself, can be found, in compliance with the relations developed above. The series of crystallization proves of great importance for the determination of the natural history species in the mineral kingdom. It is also an external character of the utmost value in the character of the species. This character requires, therefore, the dimensions of a member of the series to be stated, of which the most eligible is the fundamental form. The limits do not determine the series of crystallization, since, in the rhomboidal and in the pyramidal system, they are common to all; in the prismatic, at least to those series which possess a similar transverse section. Hence the obtaining the limiting forms is not sufficient for the character of the natural history species.

62. *General Laws of Combination.*

The second advantage flowing from the above inquiries, consists in the accurate understanding of the qualities of combinations, and of the development of their most general laws. The first of these laws stands thus: *The forms which nature combines must belong to one series of crystallization.* The second. *The combination must be effected in that position of the several simple forms it contains, which the derivation assigns to them.* Upon these two laws depends the symmetry of the combinations, which, therefore, is not the fundamental law of crystallization.

63. *Rhomboidal and Dirhomboidal Combinations.*

An accurate investigation of the combinations is one of the most interesting parts of crystallography. Without entering into minute details, some of their relations may be shortly mentioned, as they convey general ideas of the connection between different forms, and as they are, therefore, of consequence in the system of arrangement and discrimination to be explained in this article.

Combinations of the rhomboidal system, produced by simple forms in such a manner that they appear in the combination with the full number of their faces, and in their proper position, are termed *rhomboidal combinations*. Such are the most common combinations in the rhomboidal system. Suppose, on the contrary, a rhomboid to combine with itself in a turned position, it will affect the shape of a simple form, and appear as an isosceles six-sided pyramid. It is termed a *dirhomboid*, and designated by $2(R+n)$. The dirhomboids do not arrange themselves with the isosceles six-sided pyramids in the same se-

Mineralogy. ries (§ 29), because there is a difference existing in the situation of the bases in the one and in the other, as becomes evident in considering the derivation. In a similar way, two equal scalene six-sided pyramids being combined in a turned position, produce a scalene twelve-sided pyramid, which has as little right as the dirhomboid to be ranked with the simple forms, although its faces are all equal and similar to each other. Combinations produced by, or containing forms of this kind, are termed *dirhomboidal* combinations.

64. *Hemi-rhomboidal and Hemi-dirhomboidal Combinations.*

It sometimes happens in the rhomboidal system, that the forms enter only with half the number of their faces into a combination. If these combinations contain simple forms, they are said to be *hemi-rhomboidal*; if they contain any of the above mentioned compound forms under this restriction, they are said to be *hemi-dirhomboidal*. A further distinction is to be made among such combinations, in as much as the faces contiguous to one apex are either parallel, or inclined to those of the other. The *hemi-rhomboidal*, or *hemi-dirhomboidal*, are said, in the first case, to be of *parallel*, in the other to be of *inclined* faces. An example will put the importance of this difference in its full light: Enlarge in a scalene six-sided pyramid the alternating faces contiguous to one apex, and, at the same time, those of the opposite apex, which are *parallel* to the former, the resultant form will take the appearance of a rhomboid, without in reality being a form of this kind. If, on the contrary, the faces enlarged on the opposite apex are *inclined* to those of the former, the resultant form is contained under six trapezoidal faces.

65. *Pyramidal and Hemi-pyramidal Combinations.*

A relation similar to that which in the rhomboidal system has been expressed by the name of *hemi-rhomboidal*, is equally found in the pyramidal system, and here it constitutes the *hemi-pyramidal* combinations. The *hemi-pyramidal* combinations of *parallel* faces refer only to the eight-sided pyramids, which by this affect the shape of isosceles four-sided pyramids, without partaking of their other properties; those of *inclined* faces refer also to the isosceles four-sided pyramids, which yield forms analogous to the tetrahedron, whilst the result of the scalene eight-sided pyramid is a particular form, contained under eight scalene triangles.

66. *Prismatic, Hemi-prismatic, and Tetarto-prismatic Combinations.*

The differences already mentioned are particularly remarkable in the prismatic system. From what has been said in respect to the other systems, it becomes evident what is meant by *prismatic* and by *hemi-prismatic* combinations. The latter expression refers also to one or to several prisms, whose axes are parallel, if they enter into the combinations with only half the number of their faces. A similar relation of forms in the present system, marked by the expression *tetarto-prismatic*, arises, when of a scalene four-sided pyramid only the fourth part, as to the

number, of the faces appear in a combination. Such a combination can also be produced by oblique angular four-sided prisms, whose axes are perpendicular to each other, when only half the number of their faces is visible. The *hemi* and *tetarto-prismatic* combinations illustrate the *oblique*, the rectangular as well as the obliquangular prisms produced by nature. These belong altogether to the prismatic system, and none of them is a simple form.

The signs of the *hemi-rhomboidal*, *hemi-pyramidal*, and *hemi-prismatic*, are composed of the signs of the whole forms, and of the number 2, placed below them like a divisor; instead of the latter, the signs of the *tetarto-prismatic* combinations contain the number 4 as divisor.

67. *Tessular and Semi-tessular Combinations.*

Those combinations of the tessular system, into which no halves or fourths enter, are called *tessular* combinations, and in the present place they need no further explanation. Combinations of this system, however, containing halves, are termed *semi-tessular* combinations. These allow of a further distinction into *semi-tessular* combinations of *parallel* faces, and into those of *inclined* faces, as is the case in the *hemi-rhomboidal* and *hemi-pyramidal* combinations. The halves peculiar to the former are those in which every face is parallel to another, as the hexahedral pentagonal-dodecahedron, the three-edged tetragonal-icositetrahedron, and the general aspect of the forms undergoes thereby no alteration. The halves peculiar to the latter have not two faces parallel to each other, as the tetrahedron, the tetrahedral trigonal-icositetrahedron, &c., and the combination itself assumes, or at least approaches to a tetrahedral aspect.

Instead of crystallographic signs, *verbal* expressions are employed, in the characteristic part of this article, when describing the forms of the tessular system; because the use of the former is in the present system subject to much greater difficulties, without affording services either so beneficial or so numerous as in the other systems.

68. *Development of the Combinations.*

To develop a combination is to exhibit by itself each of the simple forms which it contains (§ 4). The determination of the kind of these forms has no difficulty whatever. The homologous planes of a combination being enlarged till the rest disappear, one of the forms after the other is produced. To find out their relations, upon the knowledge of which, nevertheless, depends the demonstration of the combinations, is somewhat more circumstantial, and here the series of simple forms, produced by the derivation, show their great utility. The following paragraph contains a general idea of the mode of proceeding followed for this purpose by crystallography, though its full explanation would require too much calculation to be given in this place.

69. *Line of Combination, General Formulæ for it, and their Application.*

Imagine a combination of two simple forms, whose dimensions are known, and which themselves are in

Mineralogy. such a position as is peculiar to the system of crystallization to which they belong. Suppose now two terminal edges, or two diagonals, or one terminal edge and one diagonal, that are situated in a plane which, at the same time, passes through the axis, to be prolonged, till they intersect each other above or below, in a finite or infinite distance from a horizontal plane, laid through the centre of the axis. The straight line measuring the distance between the mutual intersection of the two lengthened lines, and that in which one of the lines meets with the horizontal plane, is termed the *line of combination*. The length and situation of the line of combination are evidently dependent upon the dimensions of the combined forms; and inversely the situation of the edge of combination (§ 3.) is dependent upon the length and situation of the line of combination: for, join by a straight line the terminal point of the line of combination with one of the points of intersection between the edges and diagonals of the combined forms, amongst themselves or with each other, the prolongation of this line will equally pass through the other point of intersection, and therefore be identical with the edge of combination. Hence if two forms of a system, in a determined position, produce with a third form lines of combination equal both in length and situation, the edges of combination thus produced will be equally situated; and if the two forms enter at once into combination with the third, the edges of combination produced by the first and the third must be parallel to those between the second and the third.

Crystallography develops general formulae, expressing the quantity of the line of combination respecting the three first systems of crystallization (this not being required for the tessular system), in which due notice is taken of the kind of forms, their position, and the quality of the edges of combination, namely, whether the faces producing them are contiguous to one or to different apices of the simple forms. Of these formulae, that which answers to the circumstances of a given combination between two known simple forms, is chosen and determined for that particular case, by substituting, instead of the variable quantities, m and n occurring in them, those finite numbers, which depend upon the place of the members in the series, and those factors by which the axes of the rhomboids and others have been multiplied. Thus the quantity of the line of combination, expressed either by a terminal edge, or by a diagonal, or by the axis of one or the other form contained in the combination, is found. Another formula must now be chosen, answering to a combination between one of these known forms, and another unknown, which produces with it edges of combination parallel to those in the combination of the two known forms. The formula must be determined for the case in question, by the substitution of numbers to m and n . This can only be done in respect to the known form; m and n of the unknown remain unaltered in the expression.

This expression, as is evident from the preceding, Mineralogy. must be equal to the value of the line of combination found above. These two equal terms give an equation to be resolved for the values of m and n .

If the unknown form contains only n (as for instance it being a rhomboid, where $m=1$), it is determined in the manner already mentioned. If, on the contrary, it contains m and n at once, another equation must be established in order to determine the second quantity, which is effected in the manner shown already. Some experience in this method of developing the combinations will teach how to take advantage of certain circumstances offering themselves, by which very often it is rendered possible to argue immediately upon one of the unknown quantities m or n , or even sometimes upon both, and to determine the relations of several forms, according to such arguments, without being obliged to employ calculations.

Every simple form being thus determined as member of a series, and furnished with its crystallographic sign; the combination containing those simple forms will be designated by writing the signs for the simple forms one after the other, as some instances in the preceding § 60, have already shown. As to the order in which the signs succeed each other in designating a combination, there are two distinct methods, each of which may be applied. Either those forms, whose planes are perpendicular to the axis, are set down first, those whose planes are parallel to it, last; the rest following each other according to the greater or less inclination which their faces have toward the axis, as decreasing from 90° to 0° ; or the forms, according to their kind, are collected into series between their limits, and then set down one after the other. The designation

$$R - 1 \cdot \underset{a}{(P-2)}^3 \cdot \underset{b}{R} \cdot \underset{c}{\frac{1}{2}} \underset{d}{R} \cdot \underset{e}{R} + 1 \cdot \underset{f}{(P)}^3 \cdot \underset{g}{R} + \infty$$

represents fig. 26, according to the first method,

$$R - 1 \cdot \underset{a}{R} \cdot \underset{c}{R} + 1 \cdot \underset{e}{\frac{1}{2}} \underset{d}{R} \cdot \underset{g}{R} + \infty \cdot \underset{l}{(P-2)}^3 \cdot \underset{f}{(P)}^3$$

the same, after the second method.

70. Calculation of the Angles at the Edges of Combination.

After having developed the combination, the last office of crystallography is to calculate the angles of combination, or the incidences of the faces of different forms. In many instances this angle follows at once from those of the simple forms. If this will not do, crystallography employs general formulae for the trigonometrical functions of the edge of combination, similar to those for the line of combination, containing equally the variable quantities m and n . The development of the combinations determines these quantities, and if substituted in the said formulae, they give the value of a trigonometrical function, commonly of the co-sine of the angle, produced by two faces of different forms, meeting in the edge of combination.

* For the preceding view of the New Crystallography we are indebted to Professor Mohs, who wrote it expressly for the present article.

Mineralogy. II. CLEAVAGE. *Foliated Fracture of Werner.*

Cleavage is the property which minerals possess of splitting in certain determinate directions. The faces or planes thus obtained, which are termed the *faces of the cleavage*, are more or less smooth and shining. The forms contained under these faces are called *forms of cleavage*, or *cleavage-forms*.

The cleavage-forms represent members of the series of crystallization of those mineral species to which the mineral having the cleavage belongs. The same may be inferred of such individuals or species as possess more than one cleavage form. Hence cleavage extends the application of crystallography in the mineral kingdom, because a mineral, although it be not crystallized, may be cleavable, and thus allow the series, at least the system of crystallization, to be made out by cleavage in most of the cases, where no regular crystallizations occur.

The cleavage-forms are designated like those of crystallization. Cleavage-forms, Mohs remarks, if among the number of those, which in the preceding pages served as a basis to the derivation, are by preference chosen for representing the fundamental form in the species to which they belong; as in rhomboidal calc-spar, the rhomboid of $105^{\circ} 5'$. This rule, however, suffers an exception in the case of a rhomboid or a pyramid, which occur as cleavage-forms, being too obtuse or too acute. For this reason, in pyramidal copper pyrites, the fundamental form is P, though the cleavage-form is $P+1$. No cleavage-form, whose dimensions are infinite, can be employed as a fundamental form.

A few technical expressions are employed by Mohs in determining the cleavage, of which the following may be enumerated. Cleavage, in the three first systems of crystallization, which are those of variable dimensions, is said to be *axotomous*,* when it appears as a single plane or face perpendicular to the axis; it is said to be *paratomous*,† if it is parallel to the faces of a finite form; and *peritomous*,‡ if it takes place parallel to the axis, and equally distinct in more than one direction. In the prismatic system, the expression *prismatoidal* means a single cleavage-face parallel to the axis; and *diprismatic* denotes the cleavage to be parallel at the same time to the faces of a vertical, and to those of a horizontal obliquangular four-sided prism. The expression *monotomous*, referring to the three systems, is more general than any of the foregoing; it comprises the axotomous and the prismatoidal, and is applied where a single cleavage-face is met with, whose position in regard to the axes, that is to say, whether it is parallel or perpendicular to the axis, has not been determined. The perfection or distinctness of the cleavage, which is next to be considered, refers to the aspect of the faces of the cleavage, viz. whether these are more or less smooth or shining, whether they are streaked, &c. The most important object to be remarked in this respect, is the sameness of quality existing in the faces belonging to one and the same, and the diver-

sity of faces belonging to different cleavage-forms; Mineralogy. the latter is a particular illustrated and confirmed by the derivations of the prismatic system. The nature of the faces of the cleavage is one of the means to remove the uncertainty mentioned in § 60, on account of the right rectangular prism. Lastly, it may be remarked, that we must be careful not to confound certain faces of composition (§ 86.), which sometimes likewise keep constant directions with the cleavage-forms.

III. HARDNESS.

The degrees of hardness or their limits are by Kirwan, Mohs, and others, expressed by numbers. The most precise scale of hardness is that of Mohs, in which the degrees are determined according to the following scale:

No. 1. denotes the degree of hardness of common talc and Venetian talc.

No. 2. is the hardness of a variety of prismatoidal gypsum, with an imperfect cleavage and imperfect transparency. Varieties perfectly transparent and crystallized are commonly too soft.

No. 3. Hardness of a cleavable variety of calcareous spar.

No. 4. Hardness of fluor spar.

No. 5. Hardness of apatite.

No. 6. Hardness of prismatic felspar.

No. 7. Hardness of rhomboidal quartz.

No. 8. Hardness of prismatic topaz.

No. 9. Hardness of rhomboidal corundum.

No. 10. Hardness of octahedral diamond.

We must obtain such specimens of the minerals just enumerated as will answer for the required purpose. If we wish by means of them to ascertain the hardness of a given mineral, we first try which of the members of the scale can be scratched by one of the corners of the given mineral. We begin with the highest member of the scale, and proceed till we arrive at one which can be scratched. We now compare the hardness of the given mineral with that of the first member of the scale which can be scratched, and with that next to it which is not scratched, by passing corners of each of the same shape over the surface of a hard and fine file. The resistance which the minerals oppose to the file, and the noise produced by rubbing pieces of a nearly equal shape, allow the relation of the hardness in the given mineral to be estimated. The degree of hardness found in this way is expressed by the numbers in the scale, and if these are not sufficient, by decimals; the distance between two subsequent members being supposed to be divided into ten square parts, without, however, maintaining those distances in reality everywhere to be equal. Thus, if hardness is designated by H, that of prismatic gypsum, for example, which is 2, will be expressed $H=2$; tourmaline, which has a hardness intermediate between that of rhomboidal quartz and prismatic topaz, will be expressed by 7.5.

* From *αξων*, the axis, and *τεμνω*, I cut; cleavable in one direction.

† From *παρεα*, beside, and *τεμνω*, I cut; with cleavage planes, which are parallel with the planes of the fundamental figure, or are inclined to the axis.

‡ From *περι*, round about, and *τεμνω*, I cut; with surrounding cleavage planes parallel to the axis.

IV. SPECIFIC GRAVITY.

The specific gravity of minerals is determined by means of the hydrostatic balance, the hydrometer, and Adie's new instrument. Of these instruments, and the modes of using them, accounts are given in the *Encyclopædia Britannica* and *Edinburgh Philosophical Journal*.

II. CHARACTERS EMPLOYED IN THE DESCRIPTION OF THE SPECIES, SUB-SPECIES, KINDS, AND VARIETIES OF MINERALS.

1. Colour.—2. Common and Particular External Forms.—3. Distinct Connections.—4. Surface.—5. Lustre.—6. Fracture.—7. Shape of Fragments.—8. Transparency.—9. Opalescence.—10. Streak.—11. Soiling.—12. Tenacity.—13. Frangibility.—14. Flexibility.—15. Adhesion to the Tongue.—16. Unctuousity.—17. Smell.—18. Taste.

I. COLOUR.

The colours in the mineral kingdom are not so numerous as is generally imagined; and even the varieties, although often extremely beautiful, and apparently infinite in number, bear but a small proportion to the vast series that characterize the various productions of the vegetable and animal kingdoms. Werner, who bestowed great attention on this interesting and beautiful character, enumerates eight principal colours, viz. white, grey, black, blue, green, yellow, red, and brown. Each of these principal colours exhibits a greater or less number of varieties, many of which have been accurately defined, and are contained in the following enumeration.

I. Definitions of the different Varieties of Colour.

1. WHITE.

1. *Snow-white* is the purest colour, and nearly agrees with that of new-fallen snow. Examples of this colour occur in Carrara marble and common quartz.

2. *Reddish-white* is snow-white with a slight intermixture of red. Example, red quartz.

3. *Yellowish-white* is snow-white with very little lemon-yellow and ash-grey. Example, chalk.

4. *Silver-white* is yellowish-white with metallic lustre. Example, arsenical pyrites.

5. *Greyish-white* is snow-white mixed with a little ash-grey. Example, quartz.

6. *Greenish-white* is snow-white mixed with a very little emerald-green and ash-grey. Example, amianthus.

7. *Milk-white* is snow-white mixed with a little Berlin-blue and ash-grey. The colour of skimmed milk. Example, calcedony.

8. *Tin-white* differs from the preceding colour, principally in containing a little more grey, and having the metallic lustre. Example, native antimony.

2. GREY.

1. *Lead-grey* is ash-grey with a small portion of blue, and possesses metallic lustre. Example, lead-glance.

2. *Bluish-grey* is ash-grey mixed with a little blue. Example, limestone.

3. *Pearl-grey* is pale bluish grey intermixed with a little red. Example, porcelain jasper.

4. *Smoke-grey*, or *brownish-grey*, is dark bluish grey mixed with a little brown. Example, flint.

5. *Greenish-grey* is ash-grey mixed with a little emerald-green, and has sometimes a faint trace of yellow. Example, clay-slate.

6. *Yellowish-grey* is ash-grey mixed with lemon-yellow and a minute trace of brown. Example, calcedony.

7. *Ash-grey* is the characteristic colour. It is the colour of wood ashes. Example, quartz.

8. *Steel-grey* is dark ash-grey with metallic lustre. It is the colour of newly broken steel. Example, native platina.

3. BLACK.

1. *Greyish-black* is velvet-black mixed with ash-grey. Example, basalt.

2. *Iron-black* is principally distinguished from the preceding by its being rather darker, and possessing a metallic lustre. Example, magnetic iron-ore.

3. *Velvet-black* is the characteristic colour of this series. It is the colour of black velvet. Example, obsidian.

4. *Pitch-black*, or *brownish-black*, is velvet-black mixed with a little yellowish-brown. Example, cobalt ochre.

5. *Greenish-black*, or *raven-black*, is velvet-black mixed with a little greenish-grey. Example, hornblende.

6. *Bluish-black* is velvet-black mixed with a little blue. Example, black earthy cobalt ochre.

4. BLUE.

1. *Blackish-blue* is Berlin-blue mixed with much black, and a trace of red. Example, blue copper.

2. *Azure-blue* is Berlin-blue mixed with a little red. Example, blue copper.

3. *Violet-blue* is Berlin-blue mixed with much red and very little black. Example, amethyst.

4. *Lavender-blue* is violet-blue mixed with a small portion of grey. Examples, lithomarge and porcelain jasper.

5. *Plum-blue* is Berlin-blue, with more red than in violet-blue, and a small portion of brown and black. Example, spinel.

6. *Berlin-blue* is the purest or characteristic colour of the series. Examples, sapphire, rock-salt, kyanite.

7. *Smalt-blue* is Berlin-blue, with much white, and a trace of green. Examples, pale-coloured smalt, named eschel, earthy blue iron, earthy blue copper, and some varieties of gypsum.

8. *Duck-blue* is a dark blue colour, composed of blue, much green, and a little black. Example, ceylanite.

9. *Indigo-blue* is a deep blue colour, composed of blue, with a considerable portion of black, and a little green. Example, earthy blue iron of Eckardsberg, in Thuringia.

10. *Sky-blue* is a pale blue colour, composed of blue, green, and a little white. It is the colour of a clear sky, hence its name. Example, lenticular copper.

Mineralogy.

5. GREEN.

1. *Verdigris-green* is emerald-green mixed with much Berlin-blue and a little white. Example, copper-green and green Siberian felspar.

2. *Celandine-green* is verdigris-green mixed with ash-grey. Examples, green earth, Siberian and Brazilian beryl.

3. *Mountain-green* is emerald-green mixed with much blue, and a little yellowish-grey; or verdigris-green with yellowish-grey. Examples, beryl and glassy actynolite.

4. *Leek-green* is emerald-green, with bluish-grey and a little brown. Examples, nephrite and common actynolite.

5. *Emerald-green* is the characteristic or pure unmixed green. Example, emerald.

6. *Apple-green* is emerald-green mixed with a little greyish-white. Example, chryoprase.

7. *Grass-green* is emerald-green mixed with a little lemon yellow. Example, uranite.

8. *Blackish-green* is pistachio-green mixed with a considerable portion of black. Example, augite.

9. *Pistachio-green* is emerald-green mixed with more yellow than in grass-green, and a small portion of brown. Examples, chrysolite and epidote.

10. *Asparagus-green* is pistachio-green mixed with a little greyish white; or emerald-green mixed with yellow and a little brown. Examples, garnet, olivenite, and beryl.

11. *Olive-green* is grass-green mixed with much brown, and a little grey. Examples, common garnet, olivenite, and pitch-stone.

12. *Oil-green* is emerald-green mixed with yellow, brown, and grey; or pistachio-green, with much yellow and light ash-grey. Examples, fuller's-earth and beryl.

13. *Siskin-green* is emerald-green mixed with much lemon-yellow and a little white. Example, uran mica.

6. YELLOW.

1. *Sulphur-yellow* is lemon-yellow mixed with much emerald-green and white. Example, native sulphur.

2. *Brass-yellow* differs from the preceding yellow principally in having metallic lustre; it contains a small portion of grey. Example, copper pyrites.

3. *Straw-yellow* is sulphur-yellow mixed with much greyish-white. Example, yellow cobalt ochre.

4. *Bronze-yellow* is brass-yellow mixed with a little steel grey and a minute portion of reddish-brown. Example, iron pyrites.

5. *Wax-yellow* is lemon-yellow mixed with reddish-brown and a little ash-grey; or it may be considered as honey-yellow with greyish-white. Examples, opal and yellow lead-spar.

6. *Honey-yellow* is sulphur-yellow mixed with chesnut-brown. Examples, fluor-spar and beryl.

7. *Lemon-yellow* is the pure unmixed colour. It is the colour of the rind of ripe lemons. Example, yellow orpiment.

8. *Gold-yellow* is the preceding colour with metallic lustre. Example, native gold.

9. *Ochre-yellow* is lemon-yellow mixed with a considerable quantity of light chesnut-brown. Examples, yellow earth and jasper.

10. *Wine-yellow* is lemon-yellow mixed with a

small portion of red and greyish-white. Examples, Mineralogy, Saxon and Brazilian topaz.

11. *Cream-yellow*, or *Isabella-yellow*, contains more red and grey than the wine-yellow, and also a little brown. Examples, bole from Strigau and compact limestone.

12. *Orange-yellow* is lemon-yellow with carmine-red. It is the colour of the rind of the ripe orange. Example, uran-ochre.

7. RED.

1. *Aurora*, or *morning-red*, is carmine-red mixed with much lemon-yellow. Example, red orpiment.

2. *Hyacinth-red* is carmine-red mixed with lemon-yellow, and a minute portion of brown; or aurora-red mixed with a minute portion of brown. Examples, hyacinth and tile-ore.

3. *Tile-red* is hyacinth-red mixed with greyish-white. The colour of tiles or bricks. Example, porcelain jasper.

4. *Scarlet-red* is carmine-red mixed with a very little lemon-yellow. Example, light-red cinnabar from Wolfstein.

5. *Blood-red* is scarlet-red mixed with a small portion of black. Examples, pyrope and jasper.

6. *Flesh-red* is blood-red mixed with greyish-white. Examples, felspar and calc-spar.

7. *Copper-red* scarcely differs from the preceding variety, but in possessing metallic lustre. Example, native copper.

8. *Carmine-red* is the characteristic colour. Example, spinel, particularly in thin splinters.

9. *Cochineal-red* is carmine-red mixed with bluish-grey. Example, dark-red cinnabar.

10. *Crimson-red* is carmine-red mixed with a considerable portion of blue. Example, oriental ruby.

11. *Columbine-red* is carmine-red with more blue than the preceding variety, and, what is characteristic for this colour, a little black. Example, precious garnet.

12. *Rose-red* is cochineal-red mixed with white. Examples, red manganese and quartz.

13. *Peach-blossom-red* is crimson-red mixed with white. Example, red cobalt-ochre.

14. *Cherry-red* is crimson-red mixed with a considerable portion of brownish-black. Examples, spinel, red antimony, and precious garnet.

15. *Brownish-red* is blood-red mixed with brown. Example, clay iron-stone.

8. BROWN.

1. *Reddish-brown* is chesnut-brown mixed with a little red and yellow; or chesnut brown with a small portion of aurora-red. Example, brown-blende from the Harz.

2. *Clove-brown* is chesnut-brown mixed with cochineal-red and a little black. It is the colour of the clove. Examples, rock-crystal and brown hematite.

3. *Hair-brown* is clove-brown mixed with ash-grey. Example, wood-opal.

4. *Broccoli-brown* is chesnut-brown mixed with much blue, and a small portion of green and red. Example, zircon.

Mineralogy. 5. *Chesnut-brown* is the characteristic or pure brown colour. Example, Egyptian jasper.

6. *Yellowish-brown* is chesnut-brown mixed with a considerable portion of lemon-yellow. Examples, iron-flint and jasper.

7. *Pinchbeck-brown* is yellowish-brown with metallic lustre. Rather the colour of tarnished pinchbeck. Example, mica.

8. *Wood-brown* is yellowish-brown mixed with much pale ash-grey. Examples, mountain wood and bituminous wood.

9. *Liver-brown* is chesnut-brown mixed with olive-green and ash-grey. The colour of boiled liver. Example, common jasper.

10. *Blackish-brown* is chesnut-brown mixed with black. Examples, mineral pitch from Neufchatel and moor-coal.

II. The Play of the Colours.

If we look on a mineral which possesses this property, we observe, on turning it slowly, besides its common colours, many others, which are bright, change very rapidly, and are distributed in small spots. We observe it in the diamond when cut, and in precious opal.

III. The Changeability of the Colours.

When the surface of a mineral, which we turn in different directions, exhibits, besides its common colours, different bright colours, that do not change so rapidly, are fewer in number, and occur in larger patches than in the play of the colour, it is said to exhibit what is called the changeability of the colours. The changeability of colour is seen only in particular directions, the play of colour in all directions.

We distinguish two kinds of this phenomenon.

1st, That which is observed by looking in different positions on the mineral, as in Labrador felspar.

2d, That observed by looking through it, as in the common opal, which shows a milk-white colour when we look on its surface, but when held between the eye and the light is wine-yellow.

IV. The Iridescence.

When a mineral exhibits the colours of the prism or the rainbow, arranged in parallel, and sometimes variously curved layers, it is said to be iridescent. It is to be observed by,

1st, Looking on the mineral only, as in precious opal, adularia, &c.

2d, Both by looking on the mineral and through it, as in calcareous spar crossed by thin veins, some aragonites, rainbow calcedony, and some amethysts.

V. Tarnished Colours.

A mineral is said to be tarnished when it shows on its external surface, or on that of the distinct concretions; fixed colours different from those on its interior or fresh fracture.

Tarnished colours are *simple* or *variegated*.

I. Simple.

a. *Grey*,—white cobalt.

b. *Black*,—native arsenic.

c. *Brown*,—magnetic pyrites.

d. *Reddish*,—native bismuth.

II. Variegated.

The variegated, or party-coloured, are distinguished according to the colour of their basis. Of these the following are enumerated in the tabular view.

a. *Pavonine*, or *peacock-tail tarnish*. This is an assemblage of yellow, green, blue, red, and brown colours, on a yellow ground. The colours are nearly equal in proportion, and are never precisely distinct, but always pass more or less into one another. Example, copper pyrites.

b. *Iridescent*, or *rainbow tarnish*. In this variety the colours are red, blue, green, and yellow, on a grey ground. It is more beautiful and brighter than the preceding. Example, specular iron-ore or iron-glance of Elba.

c. *Columbine*, or *pigeon-neck tarnish*. The colours are the same as in the preceding, with this difference, that the tints of colour are paler, and the red predominates. Example, native bismuth of Schneeberg.

d. *Tempered-steel tarnish*. It consists of very pale blue, red, green, and very little yellow, on a grey ground. Example, grey cobalt.

II. COMMON AND PARTICULAR EXTERNAL FORMS

1. Common External Shape.

Common external shapes are those in which there are neither a determinate number of planes meeting under determinate angles, nor any resemblance to known natural or artificial bodies. As they occur more frequently than the other shapes, they are named *Common external shapes*.

Six different kinds are enumerated by Werner, which are distinguished according to their relative length, breadth, and thickness, their relative magnitude, and their connections with other minerals. The kinds are *massive*, *disseminated*, *in angular pieces*, *in grains*, *in plates*, and *in membranes*.

1. *Massive* is that common external shape which is from the size of a hazel-nut to the greatest magnitude, and whose dimensions, in length, breadth, and thickness, are nearly alike. It occurs imbedded in other minerals, and it is intermixed with them at their line of junction. Example, Galena or lead-glance.

2. *Disseminated* is from the size of a hazel-nut until it is scarcely visible, and its dimensions, in length, breadth, and thickness, are nearly alike. It is imbedded, and is intermixed with the inclosing mineral at the line of junction.

3. *In angular pieces*. Minerals having an angular shape, in which the length, breadth, and thickness are nearly alike, which are found loose, or slightly imbedded, and without any intermixture with the inclosing mineral at the line of junction, and from the size of a hazel-nut and upwards, are said to occur in angular pieces. It is distinguished from the massive by its occurring either loose, or not intermixed with the basis at the line of junction. Of this external shape there are two kinds:

a. *Sharp-cornered*, as in quartz.

b. *Blunt-cornered*, as in common opal.

Mineralogy.

Mineralogy.

4. *In grains.* Minerals having a roundish form, and imbedded or loose, and not much larger than a hazel-nut, are said to occur in grains.

5. *In plates.* Minerals which occur in external shapes, whose length and breadth are great in comparison of their thickness, in which the thickness is not equal throughout, and is so considerable as to allow the fracture to be distinguished, are said to occur in plates. The maximum thickness of plates is half an inch. Example, red silver.

6. *In membranes or flakes.* This shape is distinguished from the former by its thinness, as it never greatly exceeds the thickness of common paper, and the fracture cannot be seen. Example, iron pyrites.

II. PARTICULAR EXTERNAL SHAPE.

Particular external shapes differ from the common external shapes, in bearing a resemblance to natural or artificial bodies, and in being far more characteristic and varied in their aspect. There are four different sets, entitled, *longish, roundish, flat, and cavernous.*

1. Longish particular external shapes.

a. *Dentiform.* Adheres by its thick extremity, and becomes gradually thinner, incurved, and at length terminates in a free point, so that it resembles a canine tooth, whence its name. Example, native silver.

b. *Filiform.* Adheres by its thicker extremity, and terminates by an almost imperceptible diminution of thickness, and is usually curved in different directions. It is thinner and longer than the dentiform. Example, native silver.

c. *Capillary.* When the filiform becomes longer and thinner, it forms the capillary. It is generally much entangled, and sometimes the threads are so near each other that it passes into the compact. Example, native silver.

d. *Reticulated* is composed of many straight threads, which are sometimes parallel and sometimes meet each other at right angles, and form a net-like shape. Example, native silver.

e. *Dendritic.* In this external shape we can observe a trunk, branches, and twigs, which are distinguished from each other by their thickness, the trunk being the thickest. Example, native copper.

f. *Coralloidal.* When two or three branches, having rounded or pointed extremities, proceed from one stem, the coralloidal external shape is formed. There are usually many stems together. Example, calc-sinter.

g. *Stalactitic.* A mineral is said to possess a stalactitic external shape, when it consists of different straight, more or less lengthened rods, which are thickest at their attachment, and become narrower at their free extremity, which is rounded or pointed. Example, calc-sinter.

h. *Cylindrical* consists of long, rounded, straight, imperforated, usually parallel rods, which are attached at both extremities, and are generally thicker at the extremities than the middle. The interstices are either empty or filled up with another mineral. Example, galena or lead-glance.

i. *Tubiform* consists of long, usually single,

perforated tubes, which are somewhat longitudinally knotty. Example, calc-sinter.

k. *Claviform* is the reverse of *stalactitic*; it is composed of club-shaped parallel rods, which adhere by their thin extremities. Example, compact black hematite.

l. *Fruticose.* This external shape has the appearance of cauliflower. Example, calc-sinter.

2. Roundish Particular External Shapes.

a. Globular. Under this are comprehended:

a. *Perfect globular or spherical*, as in alum-slate.

β. *Imperfect globular*, as in calcedony.

γ. *Ovoidal or elliptical.* Examples, rounded masses of quartz in puddingstone.

δ. *Spheroidal.* When the spherical is compressed the spheroidal is formed. Example, Egyptian jasper.

ε. *Amygdaloidal.* When the ovoidal is compressed in the direction of its length, the amygdaloidal is formed. Example, zeolite.

b. *Botryoidal* consists of large segments of small balls, which are irregularly heaped together, and have many interstices. It resembles grapes, whence its name. Example, hematite.

c. *Reniform* consists of small segments of large balls, which are so closely set together, that no interstices are formed. Example, calcedony.

d. *Tuberosc.* This shape consists of irregular roundish or longish elevations and depressions. Example, flint.

e. *Fused-like or liquiform.* This consists of numerous very flat rounded elevations, which are generally depressed in the middle. Example, lead-glance.

3. Flat Particular External Shapes.

a. *Specular* has on one side, seldom on two opposite sides, a straight smooth shining surface. It occurs in veins. Example, galena or lead-glance.

b. *In leaves.* In this external shape there are thin leaves, which are either irregularly curved, or are straight, and have throughout the same thickness. It occurs frequently in native gold.

4. Cavernous Particular External Shapes.

a. *Cellular.* A mineral is said to be cellular, when it is composed of straight or bent tables, which cross each other in such a manner as to form empty spaces or cells. Example, quartz.

b. *Impressed.* That is, when one mineral shows the impression of any particular or regular external shape of another mineral. It borders on the cellular shape, and is formed when a newer mineral is deposited over an older, the form of which it assumes, and retains even after the impressing mineral has been destroyed or removed.

c. *Perforated* consist of long vermicular cavities, which occupy but an inconsiderable portion of the mass, and terminate on the surface in small holes. When the holes become very numerous, it passes into spongiform. Example, bog iron-ore.

d. *Corroded.* A mineral is said to be corroded when

Mineralogy. it is traversed with numerous hardly perceptible roundish holes. Example, quartz.

e. Amorphous is composed of numerous roundish and angular parts that form inequalities, between which there are equally irregular hollows. Example, silver-glance or sulphuretted silver.

f. Vesicular. When a mineral has distributed through its interior many single, usually round, elliptical, and spheroidal, also amygdaloidal, or irregularly-shaped cavities, it is said to be vesicular. Example, wacke and lava.

III. DISTINCT CONCRETIONS.

Distinct concretions are those parts into which minerals are naturally divided, and which can be separated from one another, without breaking through the solid or fresh part of the mineral. In describing them, we have to attend to the following appearances. 1. Their shape; 2. Their surface; and, 3. Their lustre.

1. Shape of the Distinct Concretions.

They are granular, lamellar, prismatic, radiated, and fibrous.

1. *Granular distinct concretions* are those in which the length, breadth, and thickness, are nearly alike. Primitive limestone or marble is composed of granular distinct concretions.

2. *Lamellar distinct concretions* are those in which the length and breadth are nearly equal, and much more considerable than the thickness. Lamellar heavy-spar affords a good example of this kind of concretion.

3. *Prismatic distinct concretions* are those in which the length is very considerable, in comparison of the thickness, or in the form of irregular prisms. Examples, amethyst and prismatic heavy spar.

4. *Radiated distinct concretions* are those in which the form is then prismatic, differing from the preceding in being narrower, and in having the form of rays. The *radiated fracture* of Werner belongs to this division. Example, radiated iron pyrites.

5. *Fibrous distinct concretions* are those in form of fibres. The *fibrous fracture* of Werner is included under this head. Example, actynolite.

2. Surface of the Distinct Concretions.

The surface varies considerably; in some it is smooth, as in hematite; in others it is streaked, as in schorl, or it is uneven, as in hornblende.

3. Lustre of the Distinct Concretions.

Here the varieties of lustre are the same as already enumerated, and therefore require no particular illustration.

IV. SURFACE.

The following are the varieties of this character:

1. *Uneven.* This, of all the kinds of external surface, presents the greatest and most irregular elevations and depressions, yet they are not so considerable as to alter the external shape. Example, surface of balls of calcedony.

2. *Granulated.* When the surface appears like shagreen, it is said to be granulated.

3. *Rough.* This kind of surface is marked with small scarcely visible elevations, which we can hardly discover but by the feel. It has little or no lustre. Example, rolled pieces of common quartz.

4. *Smooth.* Here there is no perceptible inequality, and the surface reflects more light than the preceding kinds of external surface. Example, fluor-spar.

5. *Streaked.* This kind of surface is marked with line-like elevations. It is either *simply streaked* or *doubly streaked*.

a. Simply streaked, when the line-like elevations run but in one direction.

a. Longitudinally streaked. When the streaks are parallel with the length of the lateral planes. Example, topaz.

β. Transversely streaked. When the streaks are parallel with the breadth of the lateral planes. Example, rock-crystal.

γ. Diagonally streaked. When the streaks are parallel with the diagonal of the planes. Example, garnet.

δ. Alternately streaked. When transverse and longitudinal streaks occur on alternate planes. Example, cubic iron-pyrites.

b. Doubly streaked, when the streaks run in different directions. This is of two kinds.

a. Plumiformly. When the streaks run obliquely towards a principal streak, like the disposition of the parts of a feather. Example, plumose native bismuth.

β. Reticularly. When the streaks either cross each other in a promiscuous manner, or under right angles, forming a kind of flat net-work. Example, silver-white cobalt.

c. Drusy. When a crystal is coated with a number of minute crystals of the same kind as the mineral itself, so that the new surface acquires a scaly aspect, it is denominated drusy. Example, common iron-pyrites.

V. LUSTRE.

Here we have to consider the *intensity* and the *sort* of lustre.

1. The Intensity of the Lustre. Of this there are five different degrees.

1. *Splendent.* A fossil is said to be splendid, when in full day-light (not in the sun-shine) it is visible at a great distance. Example, galena or lead-glance.

2. *Shining.* When a mineral at a distance reflects but a weak light, it is said to be shining. Example, heavy-spar.

3. *Glistening.* This degree of lustre is only observable when the mineral is near us, and at no greater distance than arms-length. Example, porcelain-jasper.

4. *Glimmering.* If the surface of a mineral, when held near to the eye in full and clear day-light, presents a very great number of small faintly shining points, it is said to be glimmering. Example, red hematite.

Mineralogy. 5. *Dull*. When a mineral does not reflect any light, or is entirely destitute of lustre, it is said to be dull. Example, chalk.

2. *The Sort of Lustre.*

The following are the different kinds of lustre.

1. *Metallic lustre*, which is always combined with opacity. It is divided into *perfect* and *imperfect*. The perfect occurs in native metals, the imperfect in tantalum ore.

2. *Adamantine*. Of this lustre there are two varieties, viz. *metallic adamantine*, and *common adamantine*. White lead spar is an example of the first, and diamond of the second.

3. *Pearly* is divided into *common* and *metallic-like*. Mica is an example of the first, and schiller-spar of the second.

4. *Resinous or waxy*. Example, pitch-stone.

5. *Vitreous or glassy*. Example, rock-crystal.

VI. THE FRACTURE.

Fracture surfaces, or planes, are those produced on breaking a mineral. The following are the principal kinds:

1. *Splintery*. When, on a nearly even fracture surface, small wedge-shaped or scaly parts are to be observed, which adhere by their thicker ends, and allow light to pass through, we say that the fracture is splintery. It sometimes passes into even. Example, quartz.

2. *Even* is that kind of fracture in which the surface is nearly even, or without inequalities. Example, Lydian-stone.

3. *Conchoidal* is composed of concave and convex roundish depressions and elevations, which are more or less regular. When regular, they are accompanied with concentric ridges, as in many shells, and hence present a conchoidal appearance. Example, obsidian.

4. *Uneven*. In this kind of fracture the surface is marked with numerous angular elevations. These inequalities are termed the *grain*, so that we have *coarse* and *fine-grained* uneven fractures. Example, copper-pyrites.

5. *Earthy*. When the fracture-surface shows a great number of very small elevations and depressions, which make it appear rough, it is called earthy. Example, chalk.

6. *Hackly*. When the fracture-surface consists of numerous small slightly-bent sharp inequalities, it is said to be hackly. Example, native copper.

7. *Slaty*. In this kind of fracture the mineral splits into tables or slates which are more or less perfect. Example, common roof-slate.

VII. THE SHAPE OF THE FRAGMENTS.

Fragments are those shapes which are formed when a mineral is so forcibly struck, that masses, having surrounding fracture-surfaces, are separated from it.

The fragments are either *regular* or *irregular*.

1. *Regular fragments* are inclosed in a certain number of regular planes, that meet under determinate angles. The following are the varieties of regular fragments:

1. *Cubic*, which occur in minerals possessing rectangular three-fold cleavage, as galena, or lead-glance, and rock-salt.

2. *Rhomboidal*, or *oblique-angular*, which occur in minerals having a three-fold cleavage, as calcareous-spar.

3. *Tetrahedral*, or *three-sided pyramidal* and *octahedral*, occur in minerals having a four-fold cleavage, in which the folia meet under equal angles, as in fluor-spar.

4. *Dodecahedral*. Fragments of this form occur in minerals having a six-fold cleavage. Example, rock-crystal.

II. *Irregular fragments* are such as have no regular form. The following are the different varieties:

1. *Cuneiform*, in which the breadth and thickness are much less than the length, and gradually and regularly diminish in magnitude from one end to the other. Example, radiated zeolite.

2. *Splintery*, in which the breadth and thickness are less considerable than the length, but without diminution of magnitude from one extremity to the other. Example, asbestos.

3. *Tabular*, in which the breadth and length are more considerable than the thickness. Example, clay-slate.

4. *Indeterminate angular*, in which the length, breadth, and thickness, are in general nearly alike, but the edges differ much in regard to sharpness, which gives rise to the following distinctions:

- a. *Very sharp-edged*, as in obsidian.
- b. *Sharp-edged*, as in common quartz.
- c. *Rather sharp-edged*, as in basalt.
- d. *Rather blunt-edged*, as in pumice.
- e. *Blunt-edged*, as in gypsum.
- f. *Very blunt-edged*, as in loam.

VIII. THE TRANSPARENCY.

This character presents the five following degrees:

1. When a mineral, either in thick or thin pieces, allows the rays of light to pass through it so completely, that we can clearly distinguish objects placed behind it, it is said to be transparent. It is either *simply transparent*, that is, when the body seen through it appears single, as in mica and selenite; or *duplicating*, when the body seen through it appears double, as in calcareous-spar.

2. *Semi-transparent*. When objects can be discerned only through a thin piece, and then always appear as if seen through a cloud. Example, calcedony.

3. *Translucent*. When the rays of light penetrate into the mineral and illuminate it, but objects cannot be observed either through thick or thin pieces, it is said to be translucent. Example, pitch-stone.

4. *Translucent on the edges*. When light shines through the thinnest edges and corners, or when the edges are illuminated in the same degree as the whole mineral in the immediately preceding variety of transparency, it is said to be translucent on the edges. Example, hornstone.

5. *Opaque*. When, even on the thinnest edges of a mineral, no light shines through, it is said to be opaque, as in chalk.

IX. THE OPALESCENCE.

Some minerals, when held in particular directions, reflect from single spots in their interior, a coloured shining lustre, and this is what is understood by opalescence.

X. THE STREAK.

By the streak we understand the appearance which minerals exhibit when scratched or rubbed with a hard body, as a knife or steel. In some instances, the colour of the mineral is changed; in others, the lustre, and frequently neither colour nor lustre are altered.

XI. THE SOILING OR COLOURING.

When a mineral, taken between the fingers, or drawn across another body, leaves some particles, or a trace, it is said to *soil* or *colour*.

XII. THE TENACITY.

By tenacity is understood the relative mobility, or the different degrees of cohesion of the particles of minerals. The degrees of tenacity are the following:

1. *Brittle*. A mineral is said to be brittle, when, on cutting it with a knife, it emits a grating noise, and the particles fly away in the form of dust, and leave a rough surface, which has in general less lustre than the fracture. Example, quartz.

2. *Sectile or Mild*. On cutting minerals possessing this degree of tenacity, the particles lose their connection in a considerable degree, but this takes place without noise, and they do not fly off, but remain on the knife. Example, galena or lead-glance.

3. *Ductile*. Minerals possessing this degree of tenacity can be cut into slices with a knife, and extended under the hammer. Example, native gold.

XIII. THE FRANGIBILITY.

By frangibility is understood the resistance which minerals oppose, when we attempt to break them into pieces or fragments. It must not be confounded with hardness. Quartz is hard, and hornblende comparatively soft; yet the latter is much more difficultly frangible than the former.

XIV. THE FLEXIBILITY.

This term expresses the property possessed by some minerals, of bending without breaking. Flexible minerals are either *elastical flexible*, that is, if when bent they spring back again into their former direction, as mica; or *common flexible*, when they can be bent in different directions without breaking, and remain in the direction in which they have been bent, as molybdena, gypsum, talc, asbestos, and all malleable minerals.

XV. ADHESION TO THE TONGUE.

This character occurs only in such minerals as possess the property of absorbing moisture, which causes them to adhere to the tongue. Example, meerschaut.

XVI. THE UNCTUOSITY.

Some minerals feel *greasy*, others *meagre*; and in

order to distinguish the different degrees of greasiness, the following distinctions are employed:

1. *Very greasy*, as talc and graphite.
2. *Greasy*, as steatite and fuller's earth.
3. *Rather greasy*, as asbestos and polished serpentine.
4. *Meagre*, as cobalt.

XVII. THE SMELL.

Of this we can give no definition, and shall therefore illustrate it by the minerals in which it occurs. It is observed under the three following circumstances:

1. *Spontaneously emitted*; in which case it is.
 - a. *Bituminous*, as mineral oil and mineral pitch.
 - b. *Faintly sulphurous*, as natural sulphur.
 - c. *Faintly bitter*, as radiated grey antimony.
2. *After breathing on it*, in which a *clayey-like* smell is produced, as in hornblende and chlorite.
3. *Excited by friction*.
 - a. *Urinous*, in stink-stone.
 - b. *Sulphurous*, in iron pyrites.
 - c. *Garlick-like*, or *arsenical*, in native arsenic and arsenic-pyrites.
 - d. *Empyreumatic*, in quartz and rock-crystal.

XVIII. THE TASTE.

This character occurs principally in the saline class, for which it is highly characteristic.

- The varieties of it are,
1. *Sweetish taste*, common salt.
 2. *Sweetish astringent*, natural alum and rock butter.
 3. *Styptic*, blue and green vitriol.
 4. *Saltly bitter*, natural Epsom salt.
 5. *Saltly cooling*, nitre.
 6. *Alkaline*, natural soda.
 7. *Urinous*, natural sal-ammoniac.

SYSTEM OF ARRANGEMENT OF SIMPLE MINERALS.

CLASS I.

Order I.—GAS.

Genus I. HYDROGEN GAS.

1. Pure Hydrogen Gas.
2. Carburetted Hydrogen Gas.
3. Sulphuretted Hydrogen Gas.
4. Phosphuretted Hydrogen Gas.

Genus II. ATMOSPHERIC AIR.

1. Pure Atmospheric Air.

Order II.—WATER.

Genus I. ATMOSPHERIC WATER.

1. Pure Atmospheric Water.

Genus II. SEA WATER.

1. Common Sea Water.

Order III.—ACID.

Genus I. CARBONIC ACID.

1. Aeriform Carbonic Acid.

Genus II. MURIATIC ACID.

1. Aeriform Muriatic Acid.

Genus III. SULPHURIC ACID.

1. Aeriform Sulphuric Acid.

Mineralogy.

2. Liquid Sulphuric Acid.
 Genus IV. BORACIC ACID.
 1. Prismatic Boracic Acid.
 Genus V. ARSENIC ACID.
 1. Octahedral Arsenic Acid.

Order IV.—SALT.

- Genus I. NATRON.
 1. Prismatic Natron.
 Genus II. GLAUBER SALT.
 1. Prismatic Glauber Salt.
 Genus III. NITRE.
 1. Prismatic Nitre.
 Genus IV. ROCK SALT.
 1. Hexahedral Rock Salt.
 Genus V. SAL-AMMONIAC.
 1. Octahedral Sal Ammoniac.
 Genus VI. VITRIOL.
 1. Hemiprismatic Vitriol, or Green Vitriol.
 2. Prismatic Vitriol, or Blue Vitriol.
 3. Pyramidal Vitriol, or White Vitriol.
 Genus VII. EPSOM SALT.
 1. Prismatic Epsom Salt.
 Genus VIII. ALUM.
 1. Octahedral Alum.
 Genus IX. BORAX.
 1. Prismatic Borax.
 Genus X. GLAUBERITE.
 1. Prismatic Glauberite.

CLASS II.

Order I.—HALOIDE.

- Genus I. GYPSUM.
 1. Prismatic Gypsum, or Common Gypsum.
 2. Prismatic Gypsum, or Anhydrite.
 Genus II. CRYOLITE.
 1. Prismatic Cryolite.
 Genus III. ALUM STONE.
 1. Rhomboidal Alum Stone.
 Genus IV. FLUOR.
 1. Octahedral Fluor.
 Genus V. APATITE.
 1. Rhomboidal Apatite.
 Genus VI. LIMESTONE.
 1. Prismatic Limestone, or Arragonite.
 2. Rhomboidal Limestone.
 3. Macrotypous Limestone.
 4. Brachytypous Limestone, or Rhomb-Spar.

Order II.—BARYTE.

- Genus I. SPARRY IRON.
 1. Rhomboidal Sparry Iron.
 * *Sphaerosiderite*.
 Genus II. RED MANGANESE.
 1. Rhomboidal Red Manganese.
 * *Manganese Spar*.
 Genus III. CALAMINE.
 1. Prismatic, or Electric Calamine.
 2. Rhomboidal Calamine.
 Genus IV. TUNGSTEN, or SCHEELIUM.
 1. Pyramidal Tungsten.

Genus V. BARYTE.

1. Pyramide-prismatic Baryte, or Strontianite.
 2. Di-Prismatic Baryte, or Witherite.
 3. Prismatic Baryte, or Heavy-Spar.
 4. Prismatic Baryte, or Celestine.

Genus VI. LEAD-SPAR.

1. Di-Prismatic Lead-Spar, or White and Black Lead-Spar.
 2. Rhomboidal Lead-Spar, or Green and Brown Lead-Spar.
 3. Hemiprismatic Lead-Spar, or Red Lead-Spar.
 4. Pyramidal Lead-Spar, or Yellow Lead-Spar.
 5. Prismatic Lead-Spar, or Sulphate of Lead.
 * 1. *Corneous Lead-Spar*.—2. *Arseniate of Lead*.—3. *Plomb Gomme*.

Order III.—KERATE.

- Genus I. CORNEOUS SILVER.
 1. Hexahedral Corneous Silver.
 Genus II. CORNEOUS MERCURY.
 1. Pyramidal Corneous Mercury.

Order IV.—MALACHITE.

- Genus I. COPPER GREEN.
 1. Uncleavable Copper Green.
 Genus II. LIRICONITE.
 1. Prismatic Liriconite, or Lenticular Arseniate of Copper.
 2. Hexahedral Liriconite, or Cubical Arseniate of Iron.
 Genus III. OLIVENITE.
 1. Prismatic Olivenite, or Prismatic Arseniate of Copper.
 2. Di-Prismatic Olivenite.
 Genus IV. BLUE MALACHITE, or BLUE COPPER.
 1. Prismatic Blue Malachite.
 * *Felvet Blue Copper*.
 Genus V. EMERALD MALACHITE.
 1. Rhomboidal Emerald Malachite.
 Genus VI. GREEN MALACHITE.
 1. Prismatic Green Malachite, or Phosphat of Copper.
 2. Di-Prismatic Green Malachite, or Common Malachite.

* ATACAMITE.

1. Prismatic Atacamite, or Muriat of Copper

Order V.—MICA.

- Genus I. COPPER-MICA.
 1. Rhomboidal Copper-Mica, or Mica-ceous Arseniate of Copper.
 2. Prismatic Copper-Mica.
 Genus II. URAN-MICA, or URANITE.
 1. Pyramidal Uran-Mica.
 * *Uran-Ochre*.
 Genus III. COBALT-MICA, or RED COBALT.
 * 1. Prismatic Red Cobalt.
 * COBALT-OGHRE.
 1. Black Cobalt-Ochre.

Mineralogy.

Mineralogy.

2. Brown Cobalt-Ochre.

3. Yellow Cobalt-Ochre.

Genus IV. **ANTIMONY-MICA, or WHITE ANTIMONY.**

1. Prismatic White Antimony.

* Antimony Ochre.

Genus V. **BLUE IRON, or IRON-MICA.**

1. Prismatic Blue Iron, or Phosphat of Iron.

Genus VI. **GRAPHITE.**

1. Rhomboidal Graphite.

Genus VII. **TALC-MICA.**

1. Prismatic Talc-Mica, or Talc.

* 1. *Native Magnesia, or Hydrate of Magnesia.*—2. *Ophite.*—3. *Pikrolite.*—4. *Nephrite.*—5. *Steatite, or Soapstone.*—6. *Figurestone, or Algalmatolite.*—7. *Magnesite.*—8. *Meerschauum.*—9. *Lithomarge.*—10. *Mountain Soap.*—11. *Bolc.*

2. Rhomboidal Talc-Mica, or Common Mica.

* Pinite.

Genus VIII. **PEARL-MICA.**

1. Rhomboidal Pearl-Mica.

Order VI.—SPAR.

Genus I. **SCHILLER-SPAR.**

1. Diatomous Schiller-Spar, or Common Schiller-Spar.

2. Axotomous Schiller-Spar, or Green Diallage.

3. Hemiprismatic Schiller-Spar, or Bronzite.

4. Prismatic Schiller-Spar, or Hypersthene.

5. Prismatic Schiller-Spar, or Anthophyllite.

Genus II. **KYANITE.**

1. Prismatic Kyanite.

Genus III. **SPODUMENE.**

1. Prismatic Spodumene.

Genus IV. **PREHNITE.**

1. Axotomous Prehnite.

* *Karpholite.*

Genus V. **DATOLITE.**

1. Prismatic Datolite.

Genus VI. **ZEOLITE:**

1. Trapezoidal Zeolite, or Leucite.

2. Dodecahedral Zeolite, or Sodalite.

3. Hexahedral Zeolite, or Analcime.

4. Paratomous Zeolite, or Cross-stone.

5. Rhomboidal Zeolite, or Chabasite.

6. Diatomous Zeolite, or Laumonite.

7. Prismatic Zeolite, or Mesotype.

8. Prismatic Zeolite, or Stilbite.

9. Hemiprismatic Zeolite.

10. Pyramidal Zeolite, or Albine.

11. Axotomous Zeolite, or Apophyllite.

Genus VI. **PETALITE.**

1. Prismatic Petalite.

Genus VII. **FELSPAR.**

1. Rhomboidal Felspar, or Nepheline.

2. Prismatic Felspar, or Common Felspar.

3. Pyramidal Felspar, or Scapolite, &c.

* *Elaolite.*

Genus VIII. **AUGITE.**

1. Paratomous Augite, or Common Augite, &c.

2. Hemiprismatic Augite, or Hornblende, &c.

3. Prismatic Augite, or Epidote.

4. Prismatic Augite, or Tabular Spar.

Genus IX. **AZURE-SPAR.**

1. Prismatic Azure-Spar, or Lazulite.

2. Prismatic Azure-Spar, or Blue Spar.

* 1. *Azure-Stone, or Lapis Lazuli.*—

2. *Haüyne.*—3. *Calaité, or Mineral*

Turquoise.—4. *Amblygonite.*—5.

Diaspore.—6. *Gehlenite.*

Order VII.—GEM.

Genus I. **ANDALUSITE.**

1. Prismatic Andalusite.

* Fibrolite. * Chiasolite.

Genus II. **CORUNDUM.**

1. Dodecahedral Corundum, or Spinel.

2. Octahedral Corundum, or Automolite.

3. Rhomboidal Corundum, or Sapphire.

4. Prismatic Corundum, or Chrysoberyl.

Genus III. **DIAMOND.**

1. Octahedral Diamond.

Genus IV. **TOPAZ.**

1. Prismatic Topaz.

Genus V. **EMERALD.**

1. Prismatic Emerald, or Euclase.

2. Rhomboidal Emerald.

Genus VI. **QUARTZ.**

1. Prismatic Quartz, or Iolite.

2. Rhomboidal Quartz.

3. Uncleavable Quartz.

4. Fusible Quartz.

Genus VII. **AXINITE.**

1. Prismatic Axinite.

Genus VIII. **CHRYSOLEITE.**

1. Prismatic Chrysolite.

Genus IX. **BORACITE.**

1. Octahedral Boracite.

Genus X. **TOURMALINE.**

1. Rhomboidal Tourmaline.

Genus XI. **GARNET.**

1. Pyramidal Garnet, or Vesuvian.

2. Tetrahedral Garnet, or Helvine.

3. Dodecahedral Garnet.

4. Prismatic Garnet, or Cinnamon-Stone.

5. Prismatic Garnet, or Grenatite.

* *Aplome.* * *Eudialite.*

Genus XII. **ZIRCON.**

1. Pyramidal Zircon.

Genus XIII. **GADOLINITE.**

1. Prismatic Gadolinite.

Order VIII.—ORE.

Genus I. **TITANIUM-ORE.**

1. Prismatic Titanium-Ore, or Sphene.

2. Peritomous Titanium-Ore, or Rutile.

3. Pyramidal Titanium-Ore, or Octahedrite.

Genus II. **ZINC-ORE.**

1. Prismatic Zinc-Ore, or Red Zinc-Ore.

Mineralogy.

Mineralogy. Genus III. RED COPPER-ORE.

1. Octahedral Red Copper-Ore.

Genus IV. TIN-ORE.

1. Pyramidal Tin-Ore.

Genus V. WOLFRAM-ORE.

1. Prismatic Wolfram.

Genus VI. TANTALUM-ORE.

1. Prismatic Tantalum-Ore.
* Tantalite.

Genus VII. URANIUM-ORE.

1. Uncleavable Uranium-Ore.

Genus VIII. CERIUM-ORE.

1. Uncleavable Cerium-Ore.
* Allanite, or Prismatic Cerium-Ore.
** Cerin.

Genus IX. CHROME-ORE.

1. Prismatic Chrome-Ore, or Chromat of Iron.

Genus X. IRON-ORE.

1. Octahedral Iron-Ore, or Magnetic Iron-Ore.
• Titanitic Iron-Ore. ** Iserine.
*** Menachanite.
2. Rhomboidal Iron-Ore, or Red Iron-Ore.
3. Prismatic Iron-Ore, or Brown Iron-Ore.
* Bog Iron-Ore. ** Lievrite.

Genus XI. MANGANESE ORE.

1. Prismatic Manganese-Ore, or Black Manganese.
* Scaly Brown Manganese-Ore.
2. Prismatic Manganese-Ore, or Grey Manganese.
* 1. Earthy Grey and Brown Manganese-Ore, or Wad.—2. Phosphat of Manganese.

Order IX.—NATIVE METALS.

Genus I. ARSENIC.

1. Native Arsenic.

Genus II. TELLURIUM.

1. Native Tellurium.

Genus III. ANTIMONY.

1. Dodecahedral Antimony.
2. Prismatic Antimony, or Antimonial Silver.

Genus IV. BISMUTH.

1. Octahedral Bismuth.

Genus V. MERCURY.

1. Liquid Native Mercury.
2. Dodecahedral Mercury, or Native Amalgam.

Genus VI. SILVER.

1. Hexahedral Silver.

Genus VII. GOLD.

1. Hexahedral Gold.

Genus VIII. PLATINA.

1. Native Platina.

Genus IX. IRON.

1. Octahedral Iron.
1. Subsp. Terrestrial Native Iron.
2. ——— Meteoric Native Iron.

Genus X. COPPER.

1. Octahedral Copper.

* 1. Osmium.—2. Palladium.—3. Mineralogy. Nickel.

Order X.—PYRITES.

Genus I. NICKEL PYRITES, or COPPER-NICKEL.

1. Prismatic Nickel Pyrites.
* Nickel Ochre.
** Black Nickel.

Genus II. ARSENIC PYRITES.

1. Axotomous Arsenic Pyrites.
2. Prismatic Arsenic Pyrites.

Genus III. COBALT PYRITES.

1. Hexahedral Cobalt-Pyrites, or Silver-White Cobalt.
2. Octahedral Cobalt-Pyrites, or Tin-White Cobalt.
* Grey Cobalt Pyrites.
** Cobalt-Kies.
*** Radiated Tin-White Cobalt Pyrites.

Genus IV. IRON PYRITES.

1. Hexahedral Iron-Pyrites.
2. Prismatic Iron-Pyrites.
3. Rhomboidal Iron-Pyrites, or Magnetic Pyrites.

Genus V. COPPER-PYRITES.

1. Pyramidal Copper-Pyrites, or Yellow Copper-Pyrites.
Undetermined Pyrites.
- * 1. Nickeliferous Grey Antimony.—2. Common Tin Pyrites.

Order XI.—GLANCE.

Genus I. COPPER-GLANCE.

1. Tetrahedral Copper-Glance, or Grey and Black Copper.
2. Prismatic Copper-Glance.
3. Prismatic Copper Glance, or Vitreous Copper.
* 1. Variegated Copper.—2. Argentiferous Copper-Glance.—3. Plumbiferous Copper-Glance.—4. Tennantite.—5. Eukairite.

Genus II. SILVER-GLANCE, or VITREOUS SILVER.

1. Hexahedral Silver-Glance.

Genus III. GALENA, or LEAD-GLANCE.

1. Hexahedral Galena, or Lead-Glance.
* Blue Lead.

Genus IV. TELLURIUM GLANCE, or BLACK TELLURIUM.

1. Prismatic Tellurium Glance.

Genus V. MOLYBDENA, or MOLYBDENA GLANCE.

1. Rhomboidal Molybdena.
* Molybdena Ochre.

Genus VI. BISMUTH GLANCE.

1. Prismatic Bismuth-Glance.
* Bismuth Ochre.
** Acicular Bismuth-Glance, or Needle Ore.

Genus VII. ANTIMONY GLANCE.

1. Prismatic Antimony-Glance.
- * 2. Prismatic Antimony-Glance, or Grey Antimony.
3. Axotomous Antimony-Glance, or Bournonite.

Mineralogy. Genus VIII. MELANE GLANCE.

1. Diprismatic Melane-Glance, Black Antimony-Ore of Werner.
2. Prismatic Melane-Glance, Brittle Silver-Glance of Werner.

Order XII.—BLENDE.

Genus I. MANGANESE-BLENDE.

1. Prismatic Manganese-Blende.

Genus II. ZINC-BLENDE, or GARNET-BLENDE.

1. Dodecahedral Zinc-Blende.

Genus III. ANTIMONY-BLENDE, or RED ANTIMONY.

1. Prismatic Antimony-Blende, or Red Antimony.

Genus IV. RUBY-BLENDE.

1. Rhomboidal Ruby-Blende, or Red Silver.
2. Peritomous Ruby-Blende, or Cinnabar.

Order XIII.—SULPHUR.

Genus I. SULPHUR.

1. Prismatic Sulphur, or Yellow Orpiment.
2. Hemi-Prismatic Sulphur, or Red Orpiment.
3. Prismatic Sulphur, or Common Sulphur.

CLASS III.

Order I.—RESIN.

Genus I. MELLILITE, or HONEY-STONE.

1. Pyramidal Mellilite, or Honey-Stone.

Genus II. MINERAL RESIN.

1. Yellow Mineral Resin, or Amber.
2. Fossil Copal.
3. Black Mineral Resin.
4. Retinite.
5. Dysodillite.

Order II.—COAL.

Genus I. MINERAL COAL.

1. Bituminous Mineral-Coal.
2. Glance-Coal.

APPENDIX.

MINERALS IMPERFECTLY KNOWN.

1. Allophane.—2. Bismuthic Silver.—3. Bloedite.—4. Fluat of Cerium.—5. Conite.—6. Cronstedtite.—7. Couzeranite.—8. Gieseckite.—9. Gismondite.—10. Hisengerite.—11. Humite.—12. Ligurite.—13. Mellilite.—14. Molybdenic Silver.—15. Orthite.—16. Polyhalite.—17. Pyrrholite.—18. Pyrothite.—19. Pyrosmalite.—20. Sapparite.—21. Skorodite.—22. Spinellane.—23. Stilpnosiderite.—24. Sordawalite.—25. Wavellite.—26. Ytrocercite.—27. Zurilite.

Mode of determining a Mineral, or of referring it to its place in the System.

The characters principally employed in the formation of what is called the *Specific Character* are the regular crystallizations (including cleavage); the de-

grees of hardness; and the specific gravity. The first *Mineralogy* character then given in the *Specific Character* is the system of crystallization to which the form and cleavage of the species belongs. Then follows, together with its dimensions (if known), the fundamental form, from which all other simple and compound forms are derived. In rhomboids, that edge which ends in the apex of the axis, that is to say, the terminal edge is given; for instance, in calcareous spar, $R=105^{\circ}5'$; in isosceles four-sided pyramids, both edges, first the terminal one, and then that on the base, are mentioned; for instance, in pyramidal zircon, $P=123^{\circ}19'$, $84^{\circ}20'$; and in scalene four-sided pyramids, first, both of the terminal edges, and then that at the basis, are given: thus, in prismatic topaz, $P=141^{\circ}7'$, $101^{\circ}52'$, $90^{\circ}55'$. In this system, besides the dimension of the finite forms, those of the infinite ones, or of the limits, are mentioned, as in the last example, $P+\infty=124^{\circ}19'$, and so on; which is very convenient, as the cases in which these can be examined occur more frequently than those in which the edges of pyramids can be measured.

After this follows the indication of the general aspect of the combinations, explained in the foregoing §§ 63–67, under the denominations of dirhomboidal, hemi-prismatic, &c. Of the former are mentioned the angles at the edges of combination, of the latter that terminal edge, which is formed by the intersection of the remaining faces of the scalene four-sided pyramid.

With respect to cleavage, the expression “cleavage, R,” for instance in rhomboidal calcareous spar, means, that this mineral has its cleavage parallel to the faces of a rhomboid, similar to the fundamental form of the species; “cleavage $P-\infty$. $P+\infty$. [$P+\infty$]” in pyramidal garnet means that this mineral has its cleavage parallel to the faces of two rectangular prisms, and at the same time perpendicular to their axis; “cleavage $Pr+\infty$ ” in prismatic chrysolite, indicates that the cleavage of this mineral passes at the same time through the axis and the short diagonal of the prism $P+\infty$; and “cleavage

($Pr+\infty$)⁵ = $87^{\circ}42'$. $Pr+\infty$. $Pr+\infty$,” expresses, for instance, in paratomous augite, that the individuals of this species can be cleaved, first parallel to the faces of an obliquangular four-sided prism, of the given dimensions; and, secondly, parallel to planes, which pass through the axis and both diagonals of the prism $P+\infty$; or, what comes to the same, parallel to the faces of a rectangular prism.

Characters mutually excluding each other.

If two or more characters, the one of which excludes the other, be coexistent in the character of an order, or of a genus, as in the genus Corundum, “Tessular, rhomboidal, prismatic,” the meaning is, that an individual belonging to this genus must be either tessular, or rhomboidal, or prismatic; because only one of these three can take place at the same time. In the specific character this never happens, because all the forms must belong to one system.

Determination of a Mineral in general.

If a mineral is to be determined, first its *form* must be made out, at least so far as to know the system to which it belongs. Then *hardness* and *specific gravity* must be tried with proper accuracy, and expressed in numbers. It is sufficient, however, to know the latter to one or two decimals. The specific character requires these data; and they are also of use in the characters of the genera, orders, and classes. This being done, the system may be consulted, and this will at the same time point out what other characters are wanting; so that a mere inspection of the mineral, or a very easy experiment, for instance, to try the streak upon a file, or, still better, upon a plate of porcelain biscuit, will be sufficient. Having advanced in this manner to the character of the species, it will, in some instances, be necessary, and in all cases advisable, for the sake of certainty, to have recourse to the dimensions of the forms. This is particularly necessary, if the genus to which the mineral belongs contains several species having forms of the same system, as is the case in the genus Augite. This determination of the dimensions of the forms may be effected by the common goniometer, the differences in the angles being in general so great, that they cannot easily be missed, even by the application of this instrument.

It will seldom be necessary to read over the whole of any character of a class, order, genus, or species, excepting those which comprise the individual; one character that does not agree sufficing for its exclusion. Thus even the characters of the orders, though the longest, will not be found troublesome.

The application of the method will become very easy and expeditious, by taking particular notice of some characters, which may be termed *prominent*. Such are a metallic aspect; a high degree of specific gravity (particularly if the mineral is not metallic), and a high degree of hardness. The observation of these will immediately decide whether an individual can belong to any particular class, order, genus, or species. It is understood, that if it be not thereby excluded, the other characters must next be examined, till either an excluding one be found, or, if not, the individual may be considered as belonging to that class, order, &c. with which it has been compared and found to agree.

Example.—In illustration of this, let us take the following example: Let the form of an unknown mineral be a combination of a scalene eight-sided pyramid, of an isosceles four-sided pyramid, and of a rectangular four-sided prism; the cleavage parallel to the faces of two rectangular four-sided prisms, in a diagonal position to each other; form and cleavage, therefore, *pyramidal*, or belonging to the pyramidal system. Let *hardness* be ≈ 6.5 ; *specific gravity* ≈ 6.9 .

In this case, both hardness and specific gravity are prominent characters, and exclude at once the individual from the first and third, but not from the second class; with the characters of which its other properties also perfectly agree. Hence the individual belongs to the second class.

Comparing the properties of the individual with

the characters of the orders in the second class, *hardness* and *specific gravity* will be found too great for the order Haloide; hardness too great for the orders Baryte and Kerate; both of them too great for the orders Malachite and Mica; and specific gravity too great for the orders Spar and Gem. But in the character of the order ore, both hardness and specific gravity fall between the fixed limits, and cannot exclude the individual from this order. The other parts of this character are now to be taken in consideration. If the lustre of the individual be metallic, its colour must be black, otherwise it cannot belong to the order ore. But the lustre is not metallic; therefore the colour of the individual is of no consequence; that is, this conditional part of the character does not affect the individual, and consequently cannot determine its place. Since the lustre is not metallic, the individual must exhibit adamantine, or imperfect metallic lustre; the first will be found particularly in the fracture. The next part of the character refers to minerals of a red, yellow, brown, or black streak; and as the individual gives none of these, its streak being white, this part of the character does not come into consideration. Hardness keeps between the limits, as stated in the character of the order ore. Should it be ≈ 4.5 and less, the streak must be yellow, red, or black; but hardness is ≈ 6.5 , therefore the colour of the streak is indifferent. If the hardness be ≈ 6.5 and more, and streak white, then the specific gravity must be ≈ 6.5 and more. Now, this condition takes place: hardness is ≈ 6.5 , and the streak is white; the specific gravity being ≈ 6.9 , which is greater than 6.5. Lastly, the specific gravity keeps within the limits.

As far as respects the individual which is to be determined, all the characters in the characteristic of the order ore may be divided into two parts. The first part contains those which refer to the individual; the second those which do not; the last afford no decisive distinctions. But with the first all the properties of the mineral agree. These properties agree consequently with the whole character of the order, as far as it is applicable to the individual, and determine it to belong to the order ore; or, in shorter terms, to be an ore.

Beginners may also compare the characters of the remaining orders. Sometimes they find one individual belonging to two orders, in which case there must be evidently a mistake in the comparison, which would perhaps not have been discovered, had they stopt at the first order, which does not exclude it. In the present case, the want of metallic lustre excludes the individual from the orders, metal, pyrites, and glance; hardness from the order blende; and both hardness and specific gravity from the order sulphur. The individual can, therefore, be nothing else than an ore; and the characters of the genera of the order Ore may now be examined.

If we consider again hardness and specific gravity as prominent, the individual will be immediately excluded from the genera titanium-ore, zinc-ore, and copper-ore, but not from the genus tin-ore. The form of the pyramidal system, and the white streak, show that it belongs to this genus. From the genus scheelium-ore, it is excluded by its

Mineralogy. too great hardness, and too low specific gravity. From the genera tantalum, uranium, cerium, chrome, iron, and manganese-ore, by hardness and specific gravity, both of them being too high; as also by its white streak, which only agrees with that genus from which the individual differs most by its hardness and specific gravity. The form also does not agree with any in these genera, consequently the individual can belong to no other than to the genus *tin-ore*.

This genus contains but one species. The conclusion that the individual must belong to this species might, nevertheless, be erroneous. There could exist a second species of this genus. The dimensions of the form must now be accurately considered. If these coincide with the angles given in the character, the highest degree of certainty that the individual belongs to or is pyramidal tin-ore, will be obtained.

Perfect determination supposes all the Characters to be known.

The perfect determination of an individual depends, as the above example has shown, upon the possibility of making out correctly those three properties, viz. form, including cleavage, hardness, and specific gravity. In botany it is the same. The characters must be observable, otherwise the determination will be impossible. In mineralogy, the method affords sometimes more: it leads to a correct determination, even if the knowledge of the form remains imperfect. But it will be an useful rule for beginners to occupy themselves at first with the determination of such individuals as present properties which can be easily and fully investigated. The rest will come of itself, when their knowledge of the mineral kingdom, and particularly of the properties of minerals, increases, and when they have by experience acquired the skill to judge properly of form and cleavage, at least, so far as is necessary for the determination of the system of crystallization, even in those cases where form and cleavage are somewhat difficult to be observed. This exercise is recommendable to every naturalist who intends to acquire a satisfactory knowledge of minerals, by means of the present method.

Immediate and Mediate Determination.

The method of determination, illustrated by an example at page 432, is termed the *immediate* determination, because it is applied immediately to the individual which is to be determined. The contrary of this is the *mediate* determination, so called on account of its mediate application to the given individual. That variety of hemiprismatic augite, which is known by the name *amianthus*, occurs in crystals so very seldom, as to withdraw their form, supposing it to be regular, from the sight, aided even by the most powerful magnifying instruments; cleavage is evidently still less observable. These crystals are flexible like fibres of flax, their hardness, therefore, cannot be estimated. Their surface has so great an extent in respect to their bulk, that they will swim in water, though endowed with a pretty considerable specific gravity, which, therefore, cannot

be ascertained. Some varieties, however, may be observed, whose crystals are a little thicker, though, in other respects, these varieties perfectly agree with *amianthus*. These varieties lose their flexibility, yet they are too frangible to be able to sustain the trial of hardness. Others are still thicker, but the dimensions of their forms cannot be ascertained on account of their minuteness. They sink in water, and scratch prismatic gypsum, but they break, if tried upon calcareous spar. By thus proceeding, we come to such varieties, as possessing a discernible form, allow the cleavage to be investigated; we find their specific gravity about three times that of the water, and their hardness between five and six. These will be immediately determinable, and be found to belong to the species of hemiprismatic augite. Chalk, rock-milk, clay-slate, and a great many other minerals not allowing of an immediate determination, are determined in the same way, and thus nothing escapes in the natural history method, which in any one of the other methods can be an object of determination.—*Vide Edinburgh Philosophical Journal*, for fuller details in regard to the determination of species, and also for a series of observations on the principles of the Natural History method.

NATURAL HISTORY OF SIMPLE MINERALS.

CLASS I.

Specific gravity under 3.8. If solid, is sapid. No bituminous smell.

Order I.—GAS.

Sp. gr. = 0.0001,—0.00014. Elastic. Not acid.

Genus I.—HYDROGEN GAS.

Evident smell. Sp. gr. = 0.0001,—0.00014.

1. Pure Hydrogen Gas.

Specific Character.—Hydrogenous smell. Sp. gr. = 0.00012.

Geognostic and Geographic Situations.—Emanates from rocks of limestone, and of the coal formation, not only in Europe, but in other quarters of the globe.

2. Empyreumatic or Carburetted Hydrogen Gas.

Specific Character.—Empyreumatic smell. Sp. gr. = 0.0008.

Geognostic and Geographic Situations.—Rises from marshes in different parts of Great Britain, and from marshes and volcanoes in other countries.

3. Sulphuretted Hydrogen Gas.

Specific Character.—Smell of putrid eggs. Taste nauseous and bitter. Sp. gr. = 0.00135.

Geognostic and Geographic Situations.—Rises from marshes, sulphureous springs, and volcanoes. It is met with in many places in Great Britain.

4. Phosphuretted Hydrogen Gas.

Specific Character.—Smell of putrid fish. Sp. gr. unknown.

Mineralogy. *Geognostic and Geographic Situations.*—It rises from marshy places, where organic substances are in a state of decomposition.

Genus II.—ATMOSPHERIC AIR.

Without smell or taste. Sp. gr. = 0.001; -0.0015.

1. *Pure Atmospheric Air.*

Specific Character.—Without smell or taste.

Forms the atmosphere which surrounds the earth.

Order II.—WATER.

Liquid. Tasteless, or with sensible taste and smell. Sp. gr. = 1.1, —1.0269.

Genus I.—ATMOSPHERIC WATER.

Without smell or taste.

1. *Pure Atmospheric Water.*

Specific Character.—Without smell or taste.

This is common rain, river, and spring water. Mineral waters might be introduced into this part of the system.

Genus II.—SEA WATER.

Sensible smell and taste.

1. *Common Sea Water.*

Specific Character.—Bitter nauseous taste, and disagreeable smell.

Is the water of the ocean.

Order III.—ACID.

Sp. gr. = 0.0045, —3.7. Acid.

Genus I.—CARBONIC ACID.

Taste slightly acid. Sp. gr. = 0.0018.

1. *Aeriform Carbonic Acid.*

Specific Character.—Elastic. Taste acidulous and pungent.

Geognostic and Geographic Situations.—Occurs in marshy places and in acidulous waters, in Great Britain and other countries.

Genus II.—MURIATIC ACID.

Smell of saffron, and strong acid taste. Sp. gr. = 0.0023.

1. *Aeriform Muriatic Acid.*

Specific Character.—Elastic. Smell pungent and suffocating.

Geognostic Situation.—Rises from volcanoes.

Genus III.—SULPHURIC ACID.

If gaseous, the smell is sulphurous. If liquid, the taste is strongly acid. Sp. gr. = 0.0025, —1.5.

1. *Aeriform Sulphuric Acid.*

Specific Character.—Elastic. Sp. gr. = 0.0028.

Geognostic Situation.—Often rises in considerable quantities from volcanoes.

2. *Liquid Sulphuric Acid.*

Specific Character.—Liquid. Sp. gr. = 1.4, —1.5.

Geognostic Situation.—Occurs in volcanic districts in Italy, America, and Java. Mineralogy.

Genus IV.—BORACIC ACID.

Solid. Sp. gr. under 3.0.

1. *Prismatic Boracic Acid.*

Specific Character.—Prismatic. Pyramid unknown. Occurs in scaly crusts. Taste first sourish, or sub-acid, then bitter and cooling, and lastly, sweetish.

Geognostic and Geographic Situations.—Found on the edges of hot springs in Italy, &c.

Genus V.—ARSENIC ACID.

Solid. Sp. gr. above 3.0.

1. *Octahedral Arsenic Acid.*

Arsenic oxyde.—*Heavy.*

Specific Character.—Tessular. Cleavage, octahedral. Taste sweetish-astringent. Hardness unknown. Sp. gr. = 3.6, —3.7.

Description.—Colour white. Occurs in delicate capillary crystals; also massive, in crusts, stalactitic, reniform and betryodal. Translucent or opaque.

Geognostic and Geographic Situations.—Occurs in veins at Andreasberg in the Hartz.

Order IV.—SALT.

Sp. gr. = 1.2, —2.9. Solid. Not acid.

Genus I.—NATRON.

Prismatic. Taste, pungent and alkaline. Hardness, = 1.0, —1.5. Sp. gr. = 1.5, —1.6.

1. *Prismatic Natron.*—Jameson.

Prismatisches Natron-Salz, *Mohs.*—Natürliches Mineral-Alkali, *Werner.*—Soudé carbonatée, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Combination, hemi-prismatic. Cleavage prismatic.

Description.—Its chief colours are grey, white, and yellow. Occurs in acicular crystals, in radiated and granular distinct concretions; also in loose earthy particles, and in crusts. Is more or less translucent.

Geognostic and Geographic Situations.—Occurs in crusts on rocks and soils of different kinds; and also in the waters of natron lakes and springs. It is particularly abundant in the natron lakes in Egypt.

Genus II.—GLAUBER SALT.

Prismatic. Taste, first cooling, then saline and bitter. Hardness, = 1.5, —2.0. Sp. gr. 1.4, —1.5.

1. *Prismatic Glauber Salt.*—Jameson.

Prismatisches Glauber Salz, *Mohs.*—Natürliches Glauber Salz, *Werner.*—Soude sulphatée, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown.

Combination, hemi-prismatic. $\frac{P}{2}$. Cleavage, $\overline{Pr} + \infty$

perfect. Less perfect, $\overline{Pr} + \infty$. (Fig. 29, 28.)

Description.—Colour white, sometimes inclining to yellow. Occurs in acicular crystals, granular con-

Mineralogy. cretions, stalactitic, in loose earthy particles, and in crusts. More or less translucent.

Geognostic and Geographic Situations.—Occurs on soils and rocks of different descriptions, in Scotland, England, and other countries.

Genus III.—NITRE.

Prismatic. Taste, cooling and saline. Hardness, =2.0. Sp. gr. 1.9, —2.0.

1. *Prismatic Nitre.*—Jameson.

Prismatisches Nitrum-Salz, *Mohs.*—Natürlicher Salpeter, *Werner.*—Potasse nitrâtée, *Haüy.*

Specific Character.—Prismatic. Pyramid =132° 22'; 91° 15'; 107° 43'. Cleavage, $P+\infty=120^\circ$.

More distinct, $Pr+\infty$. (Fig. 30, 29.)

Description.—Colour white, grey, and sometimes yellow. Occurs in acicular crystals, in crusts, and in fibrous concretions. More or less translucent.

Geognostic and Geographic Situations.—Occurs incrusting limestone, marl, sandstone, calc-tuff, chalk, and on soils of particular kinds; also incrusting the walls of limestone caves. Occurs in considerable abundance in limestone caves in Italy, in caves of various descriptions in America, and in abundance on the surface of the ground in many of the Tartarian plains.

Genus IV.—ROCK-SALT.

Tessular. Taste, saline. Hardness =2.0. Sp. gr. =2.2, —2.3.

1. *Hexahedral Rock-Salt.*—Jameson.

Hexædrisches Steinsalz, *Mohs.*

Specific Character.—Tessular. Cleavage, hexahedral.

Description.—Most frequent colours grey and white; sometimes also blue, red, yellow, and green. Occurs in granular, fibrous, radiated, and prismatic concretions; massive, dentiform, and stalactitic. Lustre between vitreous and resinous. More or less transparent and translucent.

Geognostic and Geographic Situations.—It occurs in beds, imbedded masses, and veins, associated with saliniferous clay, gypsum, limestone, sandstone, and anhydrite, in the *salt formation*; also, in layers and crusts on soils of particular kinds, and deposited on the shores of salt lakes, and in the vicinity of salt springs. Occurs abundantly in Cheshire, and also in other parts of England.

Genus V.—SAL AMMONIAC.

Tessular. Taste, pungent and urinous. Hardness =1.5, —2.0. Sp. gr. 1.5, —1.6.

1. *Octahedral Sal Ammoniac.*—Jameson.

Octædrisches Salmiac, *Mohs.*—Natürlicher Salmiac, *Werner.*—Ammoniaque Muriâtée, *Haüy.*

Specific Character.—Tessular. Cleavage, octahedral.

Description.—Colours white, grey, yellow, and sometimes green and bluish. Occurs in granular and fibrous concretions; also in efflorescences, in crusts, stalactitic, botryoidal, tuberosc, and corroded. More or less translucent.

VOL. V. PART II.

Geognostic and Geographic Situations.—Occurs in crusts in the fissures and on the surfaces of volcanic rocks, as in Vesuvius, Ætna, &c.

Genus VI.—VITRIOL.

Pyramidal, prismatic. Taste, astringent. Hardness =2.0, —2.5. Sp. gr. =1.9, —2.5.

1. *Hemi-prismatic Vitriol, or Green Vitriol.*—Jameson.

Hemiprismatisches Vitriol-Salz, *Mohs.*—Eisen Vitriol, *Werner.*—Fer Sulfatée, *Haüy.*

Specific Character.—Prismatic. Pyramid =161° 15'; 82° 20'; 103° 35', $P+\infty=24^\circ 25'$. Combination, hemi-prismatic $\frac{P}{2}=82^\circ 20'$. Cleavage, $\frac{P}{2}$.

More perfect, $Pr+\infty$. (Fig. 40.) The inclination of $\frac{P}{2}$ to $\frac{Pr}{2}+\infty=80^\circ 37'$. Green. Hardness, =2.0. Sp. gr. =1.9, —2.0.

Description.—Colour green. Occurs regularly crystallized, in fibrous concretions, massive, stalactitic, botryoidal, and reniform. More or less translucent and transparent.

Geognostic and Geographic Situations.—Occurs in coal and iron mines, both in Scotland and England.

2. *Prismatic Vitriol, or Blue Vitriol.*—Jameson.

Prismatisches Vitriol-Salz, *Mohs.*—Kupfervitriol *Werner.*—Cuivre Sulfatée, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Combination, tetartoprismatic. Cleavage, two faces, one more distinct than the other; incidence, 124° 2'. Hardness =2.5. Sp. gr. =2.2, —2.3.

Description.—Colour blue. Occurs distinctly crystallized, massive, stalactitic, and dentiform. More or less transparent and translucent.

Geognostic and Geographic Situations.—Occurs in copper mines in England and Ireland.

3. *Pyramidal Vitriol, or White Vitriol.*—Jameson.

Pyramidales Vitriol-Salz, *Mohs.*—Zink-vitriol, *Werner.*—Zinc sulfatée, *Haüy.*

Specific Character.—Pyramidal. Pyramid =120°; 90°. Cleavage unknown, and imperfect. White. Hardness unknown. Sp. gr. =2.0.

Geognostic and Geographic Situations.—Occurs in mines where blende is met with, both in Flintshire and Cornwall.

Genus VII.—EPSOM SALT.

Prismatic. Taste bitter and saline. Hardness unknown. Sp. gr. unknown.

1. *Prismatic Epsom Salt.*—Jameson.

Bittersalz, *Mohs.*—Natürlicher Bittersalz, *Werner.*—Magnesie Sulfatée, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage very imperfect prismatic.

Description.—Colours white and grey. Occurs in crusts, botryoidal, reniform, and crystallized. —varies from transparent to translucent.

Mineralogy. *Geognostic and Geographic Situations.*—Occurs along with natural alum at Hurler near Paisley.

Genus VIII.—ALUM.

Tessular. Taste sweetish, astringent, and acidulous. Hardness = 2.0, — 2.5. Sp. gr. = 1.7, — 1.8.

1. *Octahedral Alum.*—Jameson.

Octaedrisches Alaun, *Mohs.*—Natürlicher Alaun, *Werner.*

Specific Character.—Tessular. Cleavage octahedral.

Description.—Colours white. Occurs in farinaceous efflorescences, stalactitic, and in fibrous concretions,—more or less translucent.

Geognostic and Geographic Situations.—Generally occurs incrusting aluminous minerals, and in this situation it is met with in various parts of Scotland and England.

Genus IX.—BORAX.

Borax-Salz, *Mohs.*

Prismatic. Taste feebly sweetish and alkaline. Hardness = 2.0, — 2.5. Sp. gr. = 1.5, — 1.7.

1. *Prismatic Borax.*—Jameson.

Prismatisches Borax-Salz, *Mohs.*—Soude Boratée, *Haüy.*

Specific Character.—Prismatic. $P = 152^\circ 9'$; $120^\circ 23'$; $67^\circ 3'$. $P + \infty = 52^\circ 53'$. Combination, hemiprismatic, $\frac{P}{2} = 120^\circ 23'$. Cleavage $(Pr + \infty)^\circ = 88^\circ$

$9'$. More distinct $Pr + \infty$. (Fig. 32, 29.)

Description.—Colours white, grey, and green. Occurs crystallized, internally shining and resinous. Fracture, flat, conchoidal. Semitransparent.

Geognostic and Geographic Situations.—Occurs in the soil, and in the water of springs, in Thibet and Persia.

Genus X.—GLAUBERITE.

Brithyn-Salz, *Mohs.*

Prismatic. Taste feebly saline and astringent. Hardness = 2.5, — 3.0. Sp. gr. = 2.7, — 2.9.

1. *Prismatic Glauberite.*—Jameson.

Prismatisches Brithyn-Salz, *Mohs.*—Glauberite, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown.

Combination hemiprismatic. Cleavage $\frac{Pr}{2}$, perfect. Indistinct $P + \infty = 104^\circ 28'$. (Fig. 35, 30.)

Description.—Colours white and yellow. Occurs crystallized in oblique four-sided prisms. Shining lustre. Fracture conchoidal. Transparent. Brittle.

Geognostic and Geographic Situations.—Occurs in masses of rock-salt, associated with clay, at Villarubia near Ocanas, in the province of Toledo, in Spain.

CLASS II.

Specific gravity above 1.8. Insipid.

Order I.—HALOIDE.*

No metallic lustre. Streak white or grey. Hardness = 1.5, — 5.0. Sp. gr. = 2.2, — 3.3.

If pyramidal, or prismatic, the hardness = 4.0, and less. If tessular, the hardness = 4.0. If single highly perfect faces of cleavage, the Sp. gr. = 2.4, and less. If the hardness is under 2.5, the Sp. gr. = 2.4, and less. If the Sp. gr. = 2.4, and less, the hardness is under 2.5, and no resinous lustre.

Genus I.—GYPSUM.

Prismatic. Hardness = 1.5, — 3.5. Sp. gr. = 2.2, — 3.0.

If the Sp. gr. is above 2.5, there are cleavages in three directions, perpendicular to each other, and two are more distinct than the others.

1. *Prismatoidal Gypsum, or Common Gypsum.*—Jameson.

Prismatoidisches Gyps-Haloid, *Mohs.*—Chaux sulfatée, *Haüy.*

Specific Character.—Prismatic. Pyramid = $149^\circ 33'$; $135^\circ 32'$; $54^\circ 52'$. $P + \infty = 110^\circ 30'$. Combination. Hemiprismatic, $\frac{P}{2} = 149^\circ 33'$. Cleavage.

$Pr + \infty$, very perfect and distinct, $\frac{Pr}{2}$. $Pr + \infty$ (inclination to each other, = $113^\circ 6'$) (Fig. 41.) Hardness = 1.5, — 2.0. Sp. gr. = 2.2, — 2.4.

Description.—Most frequent colours white and grey; occurs also yellow, red, blue, green, brown, and even black. Occurs in regular crystals; in granular, scaly-granular, and fibrous distinct concretions; massive, disseminated, and dentiform. Lustre alternates from splendid to glimmering, and is pearly. Fracture splintery. Fragments indeterminate angular and blunt-edged. Alternates from transparent to translucent on the edges.

The transparent and highly crystallized varieties are named *selenite*; those in granular concretions, *foliated granular gypsum*; those disposed in fibrous concretion, *fibrous gypsum*; the splintery fracture characterizes the *compact gypsum*; while those varieties composed of scaly-granular concretions form the subspecies named *scaly-foliated gypsum*. Some varieties, composed of fine scaly or dusty and slightly cohering particles, are named *earthy gypsum*.

Geognostic and Geographic Situations.—*Selenite*, the purest subspecies, occurs most frequently in what are called the gypsum and salt formations of the secondary class of rocks; also in metalliferous veins of different descriptions, and in various alluvial clays and marls. The *foliated granular* subspecies occurs in beds, in transition, and secondary rocks,—being in the former intermixed with mica, in the latter with quartz, boracite, &c. The *compact variety*

* From $\alpha\lambda\varsigma$, salt; and $\eta\acute{o}\varsigma$, the appearance (habitus).

Mineralogy. occurs in considerable abundance along with the granular in the secondary gypsum formation, and the fibrous is disposed in veins, in the same formation, which also contains the *scaly foliated* and the *earthy kinds*.

The salt mines in England afford examples of nearly all the subspecies, and several of them are also met with in Scotland.

2. *Prismatic Gypsum, or Anhydrite.*—Jameson.

Prismatisches Gyps-Haloide, *Mohs.*—Muriacit, *Werner.*—Chaux Anhydro-Sulphatée, *Haüy.*

Specific Character.—Prismatic, Pyramid = $121^{\circ} 32'$; $108^{\circ} 35'$; $99^{\circ} 7'$. Cleavage, $P = \infty$. $P_r = \infty$. Less perfect $P = \infty$. Traces of $P + \infty = 100^{\circ} 8'$. (Fig. 29, 28, 27, 30.) Hardness = 3.0, —3.5. Sp. gr. = 2.7, —3.0.

Description.—Colours white, blue, red, and grey. Occurs crystallized; in granular, fibrous, and lamellar concretions; massive, and vermicularly convoluted or contorted. Lustre alternates from splendent to glistening, and is pearly. Fracture splintery and conchoidal. Alternates from transparent to translucent on the edges.

Geognostic and Geographic Situations.—Occurs massive, and in beds in the salt and secondary gypsum formations. Is frequently intermixed with rock salt, also with stinkstone, saliniferous clay, and occasionally with ores of different kinds. Some varieties are met with in transition and primitive rocks. Several of the varieties are found in the red sandstones of England and Scotland.

Genus II.—CRYOLITE.

Prismatic. Cleavage in three directions, perpendicular to each other, of which one is more perfect than the others. Hardness = 2.5, —3.0. Sp. gr. = 2.9, —3.0.

1. *Prismatic Cryolite.*—Jameson.

Kryolite, *Werner.*—Prismatisches Kryon-Haloide, *Mohs.*—Alumine fluatée alcaline, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P = \infty$. Less distinct, $P_r = \infty$. $P_r + \infty$. Traces of P . (Fig. 27, 29, 28.)

Description.—Colours white, brown, and red. Occurs massive, disseminated, and in lamellar concretions. Internally shining, and lustre vitreous, inclining to pearly. Fracture uneven. Fragments cubical. Translucent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—It has hitherto been found only in West Greenland, where it occurs in gneiss, and associated with iron pyrites and galena or lead-glance.

Genus III.—ALUMSTONE.

Alaun Haloide, *Mohs.*—Alaunstein, *Werner.*

Rhombohedral. Hardness = 5.0. Sp. gr. = 2.4, —2.6.

1. *Rhombohedral Alumstone.*—Jameson.

Rhomboedrisches Alaun Haloide, *Mohs.*

Specific Character.—Rhombohedral. Rhomboid unknown. Cleavage $R = \infty$. R .

Description.—Colours white, red, and rarely grey. **Mineralogy.** Occurs massive, porous, and vesicular. Lustre feebly glimmering. Fracture uneven. Feebly translucent on the edges. Brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in beds and large irregular masses in porphyry in Hungary, and in veins and drusy cavities in aluminous rocks at Tolfa, near to Civita Vecchia.

Genus IV.—FLUOR.

Tessular. Hardness = 4.0. Sp. gr. = 3.0, —3.3.

1. *Octahedral Fluor.*—Jameson.

Octaedrisches Flus Haloide, *Mohs.*—Chaux fluatée, *Haüy.*

Specific Character.—Tessular. Cleavage Octahedral.

Description.—Colours white, grey, black, blue, green, yellow, red, and brown. Occurs regularly crystallized, in granular, prismatic, and lamellar concretions, massive, and disseminated. Lustre from splendent to feebly glimmering, and vitreous. Fracture even, inclining to splintery and to conchoidal. More or less transparent and translucent. Brittle, and easily frangible.

The varieties, with even fracture and feeble lustre, are named *compact fluor*; those in which the cleavage is distinct are named *common* or *foliated fluor*; and some rare, dull, earthy, and loosely aggregated varieties, which occur, incrusting other minerals, are described under the name *earthy fluor*.

Geognostic and Geographic Situations.—It occurs in veins and beds in primitive gneiss, mica slate, and clay slate, in various remarkable metalliferous formations of cobalt, silver, tin, lead, copper, &c.; less frequently in transition rocks, and very abundantly in some secondary rocks, as limestone, and rarely in secondary porphyries. It is a rare mineral in Scotland, its principal localities being Monaltree, in Aberdeenshire, Banffshire, Papa Stour, in Shetland, and Gourock, in Renfrewshire. It is very abundant in several of the mining districts in England.

Genus V.—APATITE.

Rhombohedral. Hardness = 5.0. Sp. gr. = 3.0, 3.3

1. *Rhombohedral Apatite.*

Rhomboedrisches Flus-haloide, *Mohs.*—Apatit, *Werner.*—Chaux phosphatée, *Haüy.*

Specific Character.—Rhombohedral. $R = 88^{\circ} 51'$. Combination, di-rhombohedral. $2(R) = 131^{\circ} 11'$, $111^{\circ} 20'$, $(P + n)^m$ hemi-dirhombohedral, with parallel planes. Cleavage, $R = \infty$. $P + \infty$. $H = 5$. Sp. gr. = 3.0 —3.3.

Description.—Colours white, green, blue, red, yellow, and brown. Occurs regularly crystallized; in concretions which are granular, lamellar, and fibrous; massive and disseminated; lustre resinous, and varying from splendent to glimmering. Fracture conchoidal and uneven. Alternates from transparent to feebly translucent on the edges. Brittle, and easily frangible.

One set of varieties, in which the cleavage is very distinct, is named *foliated apatite*; another, in which

Mineralogy. the fracture is conchoidal, is named *conchoidal apatite*; and the varieties in which the fracture is uneven are named *phosphorite*.

Geognostic and Geographic Situations.—Occurs in gneiss, near Kincardine, in Ross-shire; in the same rock in the Shetland Islands; and in veins in greenstone, in the Island of Rùm. Several varieties are met with in Cornwall.

Genus VI.—LIMESTONE.

Kalk-Haloide.—Mohs.

Rhomboidal, prismatic. Cleavage, rhomboid-paratomous, prismatoidal. Hardness = 3.0, —4.5. Sp. gr. = 2.5, —3.2. If the hardness is above 4.0, the specific gravity = 2.8 and more.

1. Prismatic Limestone, or Arragonite.—Jameson.

Prismatisches Kalk-Haloide, Mohs—Arragon, Werner.

Specific Character.—Prismatic. Pyramid = $113^{\circ} 44'$; $93^{\circ} 13'$; $122^{\circ} 10'$. $P + \infty = 105^{\circ} 23'$. Cleavage, $Pr = 109^{\circ} 28'$. $(Pr + \infty)^2 = 61^{\circ} 4'$. More distinct $Pr + \infty$. Fig. 42. Hardness = 3.5, —4.0. Sp. gr. = 2.6, —3.0.

Description.—Colours white, grey, green, and violet-blue. Occurs regularly crystallized; also in prismatic concretions and massive. Lustre vitreous, inclining to resinous, and shining and glistening. Fracture conchoidal, passing into uneven. Translucent and transparent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs along with galena in the lead-mines of Leadhills, and in secondary trap-rocks in different parts of Scotland.

2. Rhomboidal Limestone.—Jameson.

Rhombödrisches Kalk-Haloide, Mohs.—Chaux carbonatée, Haüy.—Kalk-spath, Werner.

Specific Character.—Rhomboidal. Rhomboid = $105^{\circ} 5'$. Cleavage, R. Hardness = 3.0. Sp. gr. = 2.5, —2.8.

Description.—Colours very varied, but of all the tints, white and grey are the most frequent; besides these, the following kinds also occur, viz. red, blue, green, yellow, brown, and rarely black. Occurs regularly crystallized, and of all known minerals, exhibits the greatest number of varieties of the rhomboidal series of crystallization; also in granular, prismatic, tabular, and globular distinct concretions. Its other forms are massive, disseminated, globular, botryoidal, reniform, tuberoso, stalactitic, tubular, claviform, coralloidal, cellular, and curtain-shaped. Its lustre varies from splendid to dull, and is vitreous, inclining sometimes to pearly, sometimes to resinous. Fracture splintery, conchoidal, earthy, and uneven. Alternates from transparent to opaque. Generally brittle, and easily frangible.

Those varieties which are regularly crystallized, and possess high degrees of transparency, are named *calcareous-spar*; those in angulo-granular distinct concretions, with a lower lustre and transparency than the former, are the *foliated granular limestone*, or *crystalline marble* of authors; the varieties with

splintery or conchoidal fractures are named *compact limestone*; other varieties having a grey or brown colour, dull earthy fracture, and which, on rubbing, give out a sulphureo-bituminous smell, are named *stinkstone*; the black varieties in granular and prismatic concretions, or with a compact fracture, with a glimmering or shining lustre, and low degree of translucency on the edges or complete opacity, and which, on rubbing, yield a sulphureo-bituminous odour, are named *anthraconite*; those limestones which have the oolitic structure, or are composed of spherical granular concretions, set on a marly basis, are named *roestone* or *oolite*; the soft varieties with earthy fracture and white colour are named *chalk*; the varieties with dull fracture surface, in loosely cohering pieces and crusts, and so light as nearly to swim upon water, are named *aguric mineral*; the fibrous varieties are named *common fibrous limestone* or *satin-spar*, and *fibrous calc-sinter*, or calcareous alabaster; the earthy looking opaque varieties that occur in many particular external shapes, near calcareous springs, and on the borders of lakes, are named *calc-tuff*; while the varieties in spherical round granular concretions, and concentric lamellar concretions, found near hot springs, are named *pea stone*; the *slate-spar* of mineralogists is a variety in lamellar concretions, with a beautiful pearly lustre and feeble translucency; varieties with earthy fracture, more or less inclined to splintery and conchoidal, are named *marl*; and, lastly, the opaque dull black varieties, with slaty fracture, are named *bituminous marl-slate*.

Geognostic Situation.—This mineral is one of the most abundant and widely distributed with which we are acquainted. Calcareous spar, one of its principal kinds, occurs in every rock from granite to the newest member of the secondary series. It generally occurs in veins with numerous metalliferous minerals, and assists in an eminent degree in characterizing the vast host of mineral veins in primitive, transition, and secondary rocks. In the state of granular, foliated, and compact limestones, also in the form of oolite, chalk, and Lucullite, it forms beds, hills, mountains, and even ranges of mountains. The beautiful fibrous limestone or satin spar occurs in veins in clay slate, and in rocks of the coal formation, while all the beautiful forms of calc-sinter are met with ornamenting the walls and floors of caverns in limestone and other formations; calc tuff abounds around cold, and also warm springs, frequently incrusting organic bodies, forming the calcareous incrustations so well known to mineralogists. Pea-stone is also a production of warm springs. The white, porous, and nearly supernatant mineral aguric incrusts rocky cliffs, particularly in limestone hills, and the rare variety, named slate spar, has hitherto been found only in primitive limestone.

Geographic Situation.—England and Scotland abound in interesting varieties of calcareous spar, and the mountains, hills, and valleys of Great Britain afford numerous localities of many of the different kinds of marble, limestone, chalk, marl, Lucullite, and oolite, while its calcareous springs, and caves and caverns, exhibit numerous deposits of calc tuff and of calc sinter.

Mineralogy.

3. *Macrotypous** *Limestone*.—Jameson.

Macrotypes Kalk-haloid, *Mohs*—Braunspath, Rhombspath-Dolomite, *Werner*.—Chaux carbonatée ferrifère perlée, Chaux carbonatée magnésifère, *Hauy*.

Specific Character.—Rhomboidal. Rhomboid 106° 15'. Cleavage, rhomboidal. Hardness = 3.5, —4.0. Sp. gr. = 2.8, —2.95.

Description.—Colours white, grey, brown, red, and green. Occurs crystallized in rhomboids, in granular and prismatic concretions; massive, disseminated, globular, stalactitic, reniform, and with tabular and pyramidal impressions. Lustre varies from shining to glimmering, and is pearly, sometimes inclining to vitreous. Fracture splintery, conchoidal, and slaty. Varies from transparent to translucent on the edges. Brittle, and easily frangible.

The white varieties in small and fine granular concretions, which are sometimes so loosely aggregated, as to separate by the mere pressure of the finger, are the *dolomite-marble* of mineralogists; the *magnesian limestone* of England is a dolomite with brown colours, the green varieties are described under the name *Miemite*, from Miemo in Tuscany, where they were first found; the brown, red, reddish white, and pearl grey varieties, with very distinct pearly lustre, are arranged together, and described under the names *brown spar* and *pearl spar*.

Geognostic and Geographic Situations.—The dolomite marble occurs in the island of Iona; the brown dolomite constitutes a secondary limestone formation very abundant in England; the brown spar and pearl spar are not unfrequent in the lead-mines of Scotland and England.

4. *Brachytypous*† *Limestone or Rhomb-Spar*.—Jameson.

Brachytypes Kalk-haloid, *Mohs*. Rautenspath, *Werner*. Chaux carbonatée magnésifère, *Hauy*.

Specific Character.—Rhomboidal. Rhomboid = 107° 22'. Cleavage rhomboidal. Hardness = 4.0, —4.5. Sp. gr. = 3.0, —3.2.

Description.—Colours white, grey, and yellow. Occurs crystallized in rhombs; also massive and disseminated. Lustre splendid and vitreo-pearly. Fracture imperfect conchoidal. More or less translucent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs imbedded in chlorite-slate on the banks of Loch Lomond, and associated with galena, copper pyrites, and blende, near Newton Stewart, in Galloway.

Order II.—BARYTE.

No true metallic lustre. Streak, white and grey, or orange yellow. Hardness = 2.5, —5.0. Sp. gr. = 3.3, —7.3. If adamantine, or imperfect metallic lustre, the Sp. gr. = 6.0 and more. If the streak is orange-yellow, the Sp. gr. = 6 and more; and the hardness = 3.0 and less. If the Sp. gr. is under 4.0, and the hardness = 5.0, the cleavage is diprismatic.

Genus I.—SPARRY IRON.

Mineralogy.

Rhomboidal. Hardness = 3.5 —4.5. Sp. gr. = 3.6, —3.9.

1. *Rhomboidal Sparry Iron*.—Jameson.

Brachytypen Parachros Baryte, *Mohs*.—Spath Eisenstein, *Werner*.—Fer Oxyde Carbonaté, *Hauy*.

Specific Character.—Rhomboidal. Rhomboid = 107°. Cleavage, rhomboidal.

Description.—Colours yellow, white, brown, and black. Occurs crystallized in rhombs; also in granular concretions, massive and disseminated. Internally, lustre pearly, and varying from shining to glimmering, and even to splendid. Fracture sometimes splintery. Translucent on the edges. Rather brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in metalliferous veins, and in common veins, in primitive, transition, and secondary rocks in different parts of Great Britain and Ireland.

* *Sphaerosiderite*.

Fer oxyde carbonaté concretionné.

Colours brownish black, blackish brown, yellow, and grey. Occurs in stellular fibrous concretions, also globular, reniform, and small botryoidal. Lustre shining and resinous-pearly. Fracture uneven. Ranges from semitransparent to opaque. Occurs in drusy cavities in secondary trap rocks, along with calcareous spar, arragonite and calcedony, at Steinhilf near Hanau, in Germany.

Genus II.—RED MANGANESE.

Hardness = 3.5. Sp. gr. = 3.3, —3.6

1. *Rhomboidal Red Manganese*.—Jameson.

Macrotyper Parachros Baryte, *Mohs*. Rother Braunstein, *Werner*. Manganese Oxide Carbonaté, *Hauy*.

Specific Character.—Rhomboid = 106° 51'. Cleavage, rhomboidal.

Description.—Colours red and brown. Occurs in granular concretions, also in fibrous concretions which are scopiformly and stellularly arranged, massive, and reniform. Lustre varies from shining to glimmering, and pearly. Fracture splintery. More or less translucent on the edges; in some rare varieties translucent. Brittle, and rather easily frangible.

The varieties with distinct cleavage are named *foliated red manganese*; those in fibrous concretions *fibrous red manganese*; and the splintery varieties *compact red manganese*.

Geognostic and Geographic Situations.—Occurs in Fapnie, in Transylvania, and at Catharinenberg, in Siberia.

* *Manganese Spar*.—Jameson.

Rothstein. Manganèse Oxyde Silicifère.

Specific Character.—Colour bright rose-red. Occurs massive and disseminated. Lustre intermediate

* From μακρὸς, long; and τύπος, the type (fundamental form).

† From βραχύς, short, and τύπος, the type.

Mineralogy. between pearly and vitreous. Cleavage sometimes visible. Fracture conchoidal or splintery. Translucent on the edges. Hardness = 5.0, —5.5. Sp. gr. = 3.5, —3.7.

Geognostic and Geographic Situations.—Occurs in beds of magnetic iron-ore and iron-glance, in gneiss at Langbanshytta, in Wermeland in Sweden.

Genus III.—CALAMINE.

Zinc-Baryt, *Mohs.*

Rhomboidal. Prismatic. Hardness = 5.0. Sp. gr. = 3.3, —4.5. If rhomboidal, the Sp. gr. above 4.0.

1. *Prismatic Calamine, or Electric Calamine.*—Jameson.

Prismatischer Zink-Baryt, *Mohs.* Zink Oxyd, *Haüy.*

Specific Character.—Prismatic. Pyramid = $134^{\circ} 59'$; $99^{\circ} 56'$; $96^{\circ} 56'$. $P + \infty = 118^{\circ} 29'$. Cleavage, $P\bar{r} = 120^{\circ}$. More distinct, $(P\bar{r} + \infty)^3 = 80^{\circ} 4'$. (Fig. 43.) Hardness = 5.0. Sp. gr. = 3.3, —3.6.

Description.—Most frequent colours white and yellow; also green, grey, yellow, and brown; and with curved striped colour delineations. Occurs regularly crystallized, and in distinct concretions, which are scopiform radiated, and scopiform fibrous, granular, and curved lamellar. Massive, in crusts, stalactitic, reniform, botryoidal, and cellular. Internally alternates from glistening to dull, and lustre pearly, inclining to adamantine. Fracture small and fine-grained uneven. Varies from transparent to opaque.

Geognostic and Geographic Situations.—Occurs in veins of galena, in greywacke, and clay-slate, and in beds, and imbedded masses in secondary limestone. Is found in the lead mines of Wanlockhead, and in the mines of Flintshire and Leicestershire.

2. *Rhomboidal Calamine.*—Jameson.

Rhomboedrischer Zink-baryt, *Mohs.*—Galmei, *Werner.*—Zink carbonatée, *Haüy.*

Specific Character.—Rhomboidal. Rhomboid = 110° (nearly). Cleavage, rhomboidal. Hardness = 5.0. Sp. gr. = 4.2, —4.5.

Description.—Colours white, grey, green, yellow, and brown. Occurs regularly crystallized, and in distinct concretions, which are radiated, granular, and curved lamellar; massive, corroded, reniform, stalactitic, botryoidal, and cellular. Internally ranges from shining to dull, and is pearly. Fracture uneven, splintery, and flat conchoidal. Ranges from transparent to opaque.

Geognostic and Geographic Situations.—Occurs in beds, veins, nests, filling up or lining hollows, in transition limestone and in secondary limestone. Derbyshire, Somersetshire, Flintshire, and Durham, afford numerous localities of this mineral.

Genus IV.—TUNGSTEN, or SCHEELIUM.

Hardness = 4.0, —4.5. Sp. gr. = 6.0, —6.1.

1. *Pyramidal Tungsten.*—Jameson.

Pyramidaler Scheel-Baryt, *Mohs.*—Schwerstein, *Werner.*—Scheelin Calcaire, *Haüy.*

12

Specific Character.—Pyramidal. Pyramid = $107^{\circ} 26'$; $113^{\circ} 36'$. Combination hemi-pyramidal with parallel planes. Cleavage, $P. P + 1 = 100^{\circ} 8'$; $130^{\circ} 20' P = \infty$.

Description.—White is the principal colour; but other varieties, as brown and orange-yellow, occasionally occur. Sometimes crystallized, and also in distinct concretions, which are granular, prismatic, and curved lamellar. Occurs massive and disseminated. External lustre shining and splendid; internal lustre shining and resinous. Fracture uneven or conchoidal. More or less translucent, seldom transparent.

Geognostic and Geographic Situations.—Occurs along with tinstone, wolfram, magnetic iron-ore, and brown iron-ore, in primitive rocks, as in Cornwall.

Genus V. BARYTE.

Hardness = 3.0, —3.5. Sp. gr. 3.6, —4.6.

1. *Pyramido-Prismatic Baryte, or Strontianite.*

Pyramido-prismatischer Hal-Baryt, *Mohs.*—Strontian, *Werner.*—Strontiane Carbonatée, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown.

Cleavage, $P\bar{r}. P + \infty = 117^{\circ} 19'$. $P\bar{r} + \infty$. (Fig. 46.) Hardness = 3.5. Sp. gr. 3.6, —3.8.

Description.—Colours green and grey. Occurs regularly crystallized, and in distinct concretions, which are scopiform radiated, and scopiform fibrous. Lustre shining, glistening, and pearly. Fracture uneven. More or less translucent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs at Strontian in Scotland in veins of lead glance that traverse gneiss.

2. *Di-prismatic Baryte or Witherite.*—Jameson.

Di-prismatischer Hal-baryt, *Mohs.* Witherit, *Werner.* Baryte carbonatée, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P\bar{r}. P + \infty = 120^{\circ}$ (nearly). $P\bar{r} + \infty$. (Fig. 46.) Hardness = 3.0, —3.5. Sp. gr. = 4.2, —4.4.

Description.—Colours white, grey, and yellow. Occurs regularly crystallized, and also in distinct concretions, which are radiated and granular. Occurs massive, cellular, globular, botryoidal, reniform, and stalactitic. Lustre shining and resinous. Fracture uneven, inclining to splintery. Translucent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in galena veins, that traverse limestone and sandstone, in Cumberland and Durham.

3. *Prismatic Baryte, or Heavy-Spar.*—Jameson.

Prismatischer Hal-baryte, *Mohs.*—Schwerspath, *Werner.*—Baryte sulphatée, *Haüy.*

Specific Character.—Prismatic. Pyramid = $128^{\circ} 54'$; $91^{\circ} 20'$; $110^{\circ} 25'$. $P + \infty = 116^{\circ} 38'$. Cleavage $P\bar{r} = 78^{\circ} 28'$. $P\bar{r} + \infty$. Fig. 45. Less distinct, $P = \infty$. $P\bar{r} + \infty$. (Fig. 33, 29, 27, 28.) Hardness = 3.0, —3.5. Sp. gr. = 4.1, —4.6.

Description.—Colours white, grey, black, blue,

Mineralogy. green, yellow, red, and brown. Occurs regularly crystallized; also in granular, lamellar, fibrous, and prismatic distinct concretions; massive, disseminated, reniform, botryoidal, and globular. Lustre alternates from splendid to glimmering, and resinous or pearly, inclining to vitreous. Fracture uneven, splintery, and earthy. Alternates from transparent to opaque. Brittle, and very easily frangible.

The varieties with uneven and splintery fracture are named *compact h. spar*; those in fine granular concretion *granular h. spar*; the lamellar varieties are named *straight or curved lamellar h. spar*, according to the direction of the lamellar concretion; the fibrous varieties *fibrous h. spar*; the radiated varieties *radiated h. spar*; those in prismatic concretions *prismatic h. spar*; the varieties which, on rubbing, emit a hepatic smell, *fatid h. spar*, or *hepatite*; and those which occur in the earthy or powdery state, *earthy h. spar*.

Geognostic and Geographic Situations.—It occurs in veins, either alone or associated with various metalliferous formations of silver, copper, lead, cobalt, antimony, manganese, zinc, arsenic, iron, &c. in rocks of the primitive, transition, and secondary classes. Numerous localities of this mineral occur in Scotland, England, and Ireland.

4. *Prismatoidal Baryte, or Celestine.*—Jameson.

Prismatoidischer Hal-baryt, *Mohs.*—Celestin, *Werner.*—Strontiane sulphatée, *Haüy.*

Specific Character.—Prismatic. Pyramid = $128^{\circ} 14'$; $113^{\circ} 26'$; $90^{\circ} 57'$; $P+\infty=103^{\circ} 0'$. Cleavage, $Pr=104^{\circ} 48'$. More distinct, $Pr+\infty$. (Fig. 45.) Less distinct, $P-\infty$ $Pr+\infty$. (Fig. 33, 29, 27, 28.) Hardness = 2.0, —3.5. Sp. gr. = 3.6, —4.0.

Description.—Colours white, blue, and red. Occurs regularly crystallized; in granular, fibrous, and radiated distinct concretions; massive and stalactitic. Lustre alternates from splendid to glimmering, and is pearly. Ranges from transparent to translucent on the edges.

Geognostic and Geographic Situations.—Occurs in limestone, in red sandstone, and gypsum, where it is associated with sulphur, and in vesicular cavities in amygdaloid. It has been found in sandstone near Inverness; in the amygdaloid of the Calton Hill; in the neighbourhood of Bristol; and near Knaresborough, in Yorkshire.

Genus VI.—LEAD SPAR.

Blei-baryt, *Mohs.*

Rhombohedral, pyramidal, prismatic. Hardness = 2.5, —4.0. Sp. gr. = 6.0, —7.3. If the hardness is above 3.5, the sp. gr. = 6.5, and more.

1. *Di-prismatic Lead-Spar, or White Lead-Spar.*—Jameson.

Di-prismatischer Blei-baryt, *Mohs.*—Plomb carbonatée, *Haüy.*

Specific Character.—Prismatic. Pyramid = $130^{\circ} 0'$; $108^{\circ} 28'$; $92^{\circ} 19'$. $P+\infty=108^{\circ} 16'$. Cleavage, $Pr=117^{\circ} 13'$. ($Pr+\infty$) $^2=69^{\circ} 20'$. (Fig. 43.) Hardness = 3.0, —3.5. Sp. gr. = 6.3, —6.6.

Description.—Principal colour white, occurs also black, yellow, brown, and grey. Occurs regularly crystallized; massive and cellular. Lustre externally ranges from splendid to shining; internally from shining to glistening, and is adamantine, inclining more or less to resinous and imperfect metallic. Fracture uneven and conchoidal. Ranges from transparent to opaque. Streak greyish-white.

Geognostic and Geographic Situations.—Occurs in veins in granite, gneiss, mica slate, and clay slate; also in limestone, greywacke, and in various secondary formations. Well known localities are Leadhills and Wanlockhead.

2. *Rhombohedral Lead-Spar, or Green and Brown Lead-Spar.*—Jameson.

Rhomboedrischer Blei-Baryt, *Mohs.* Plomb Phosphaté, *Haüy.*

Specific Character.—Rhombohedral. Rhomboid = $117^{\circ} 23'$. Combination, di-rhombohedral. 2 (R)' = $134^{\circ} 15'$; $101^{\circ} 32'$. Cleavage, $P+1=141^{\circ} 47'$; $81^{\circ} 46'$. Hardness = 3.5, —4.0. Sp. gr. = 6.9, —7.3.

Description.—Colours green, brown, and sometimes yellow and white. Occurs regularly crystallized; also in granular, radiated, and curved lamellar concretions. Lustre externally shining, internally glistening, and resinous. Fracture uneven or splintery. Ranges from translucent to translucent on the edges. Streak white.

Geognostic and Geographic Situations.—Occurs in veins, and most abundantly in their upper part, in various rocks of the primitive, transition, and secondary classes, where it is associated with galena, white lead-spar, &c. Leadhills and Wanlockhead are well known localities.

3. *Hemi-Prismatic Lead-Spar, or Red Lead-Spar.*

Hemi-prismatischer Blei-Baryt, *Mohs.*—Roth Bleierz, *Werner.*—Plomb Chromaté, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Combination, hemi-prismatic. Cleavage, $P+\infty=90^{\circ}$ (nearly), $Pr+\infty$, $Pr+\infty$. (Fig. 30, 29, 28.) Hardness = 2.5. Sp. gr. = 6.0, —6.1.

Description.—Colour hyacinth red. Occurs regularly crystallized; also massive, and in flakes. Internally shining or splendid, and lustre adamantine. Fracture uneven, sometimes imperfect conchoidal. More or less translucent. Streak between lemon-yellow and orange-yellow. Nearly sectile, and easily frangible.

Geognostic and Geographic Situations.—Occurs in a granular quartz rock, associated with brown ironstone, iron-pyrites, green lead-spar, native gold, galena, and quartz, in Siberia; also in sandstone in the Brazils.

Green Chromate of Lead.

The green and liver-brown coloured mineral, in small reniform and stalactitic forms, which accompanies the red lead-spar of Siberia, and also that of Brazil, according to Berzelius, contains the following constituent parts: Oxide of lead, 60.87; oxide of copper, 10.80; chromic acid, 28.33 = 100;

4. *Pyramidal Lead-Spar, or Yellow Lead-Spar.*

Pyramidaler Blei-Baryt, *Mohs.*—Gelb Bleierz, *Werner.*—Plomb molybdate, *Haüy.*

Mineralogy *Specific Character*.—Pyramidal. Pyramid = $99^{\circ} 40'$; $131^{\circ} 35'$. Cleavage, $P-\infty$. P. Hardness = 3.0. Sp. gr. = 6.5, —6.9.

Description.—Colour yellow. Occurs crystallized; also massive, in crusts, and cellular. Externally generally splendid and shining; internally shining or glistening, and lustre resino-adamantine. Fracture uneven and conchoidal. Translucent, or translucent on the edges.

Geognostic and Geographic Situations.—Occurs in compact limestone, at Bleiberg in Carinthia; also in France and Saxony.

5. *Prismatic Lead-Spar, or Sulphate of Lead.*

Prismatischer Blei-Baryt, *Mohs*.—Vitriol Bleierz, *Werner*.—Plomb sulphaté, *Haüy*.

Specific Character.—Prismatic. Pyramid = $122^{\circ} 35'$; $94^{\circ} 25'$; $112^{\circ} 37'$. $P+\infty=109^{\circ} 28'$. Cleavage, $Pr=78^{\circ} 28'$. More distinct, $Pr+\infty$. (Fig. 45.) Hardness = 3.0. Sp. gr. = 6.2, —6.3.

Description.—Colour white, seldom green or wine yellow, or blue (owing to blue malachite). Occurs regularly crystallized; in granular distinct concretions; also massive and disseminated. Lustre adamantine, and ranging from splendid to shining. Fracture conchoidal. Transparent or translucent.

Geognostic and Geographic Situations.—Occurs in galena veins, at Leadhills and Wanlockhead; and also in the Pary's Mine in Anglesea.

1. *Corneous Lead Ore, or Muriat of Lead*.—This rare mineral, which has been hitherto found only in Derbyshire, has not been described in a satisfactory manner.

Appendix of undetermined Lead-Spars.

2. *Arseniate of Lead*.—This is a rare mineral, hitherto not well described. Is found in Cornwall, and in several mines in France and Spain.

3. *Plomb Gomme*.—This rare mineral is of a reddish or yellowish brown colour, and the colours are disposed in stripes. Occurs small reniform, and in fibrous concretions. It is shining and translucent. It is a compound of oxide of lead, alumina, and water, according to Berzelius. It has been hitherto found only in the lead mines of Huelgoet in France.

N. B.—It bears a striking resemblance to hyalite.

Order III.—KERATE.

No metallic lustre. Streak white or grey. No single distinct cleavage. Hardness = 1.0, —2.0. Sp. gr. = 5.5.

Genus I.—CORNEOUS SILVER.

Hardness = 1.0, —2.0. Sp. gr. = 5.5, 5.6.

1. *Hexahedral Corneous Silver*.—Jameson.

Hexedrisches Perl Kerat, *Mohs*.—Hornerz, *Werner*.—Argent Muriaté, *Haüy*.

Specific Character.—Tessular. Cleavage not visible. Malleable. Sectile.

Description.—Colour pearl-grey, which passes into white, blue, and green; on exposure to light becomes brown. Occurs crystallized; in prismatic and

granular concretions; massive and in flakes. Lustre ranges from shining to glistening, and is resinous. Fracture conchoidal. Translucent, or feebly translucent on the edges. Becomes shining in the streak.

Geognostic and Geographic Situations.—Occurs in silver-mines in Siberia, America, and has also been found in Cornwall.

Genus II.—CORNEOUS MERCURY.

Hardness = 1.0, 2.0. Sp. gr. unknown.

1. *Pyramidal Corneous Mercury*.—Jameson.

Pyramidales Perl Kerate, *Mohs*.—Quecksilber Hornerz, *Werner*.—Mercure, Muriaté, *Haüy*.

Specific Character.—Pyramidal. Pyramid unknown. Cleavage, $P+\infty$, imperfect. Sectile.

Description.—Colour grey. Occurs generally in very minute crystals in vesicular cavities. Lustre shining and adamantine. Faintly translucent.

Geognostic and Geographic Situations.—Occurs in the mercury-mines of Almaden, Idria, and Bohemia.

Order IV.—MALACHITE.

No metallic lustre. Colour blue, green, brown. No single distinct faces of cleavage. Hardness = 2.0, —5.0. Sp. gr. = 2.0, —4.6. If brown, in colour or in streak, the hardness = 3.0. and less; and the specific gravity above 2.5. If white in the streak, the specific gravity = 2.2, and less; and the hardness under 3.0.

Genus I.—COPPER GREEN.

Staphylin Malachit, *Mohs*

Uncleavable. Hardness = 2.0, —3.0. Sp. gr. = 2.0, —2.2.

1. *Uncleavable Copper Green*.—Jameson.

Untheilbarer Staphylin-Malachit, *Mohs*. Kupfergrün, *Werner*. Cuivre Carbonaté, *Haüy*.

Specific Character.—Reniform, botryoidal. No cleavage.

Description.—Colour green. Occurs massive, disseminated, in crusts, reniform, and botryoidal. Lustre shining, glistening, and resinous. Fracture small, conchoidal. Ranges from translucent to translucent on the edges. Colour does not change in the streak.

Geognostic and Geographic Situations.—Occurs in copper-mines in Cornwall.

Genus II.—LIRICONITE.*

Lirikon-Malachit, *Mohs*.

Tessular, prismatic. Hardness = 2.5. Sp. gr. = 2.8, —3.0.

1. *Prismatic Liriconite, or Lenticular Arseniate of Copper*.—Jameson.

Prismatischer Lirikon-Malachit, *Mohs*.—Linsen-nerz, *Werner*.—Cuivre arseniaté, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, Pr . $P+\infty$. (Fig. 35, 30.) Streak pale verdigris-green, ... Sky-blue. Hardness = 2.5. Sp. gr. = 2.8, —3.0.

Description.—Colour blue, inclining more or less to verdigris-green. Occurs regularly crystallized. Lustre shining, glistening, and pearly, passing to vitreous. Fracture uneven. Translucent. Brittle, and uncommonly easily frangible.

Geognostic and Geographic Situations.—Occurs in the copper-mines of Cornwall.

2. Hexahedral Liviconite, or Cubical Arseniate of Iron.—Jameson.

Hexaedrischer Livicon-Malachit, *Mohs.*—Wurfelierz, *Werner.*—Fer Arseniaté, *Haüy.*

Specific Character.—Tessular. Combination, semi-tessular, with inclined planes. Cleavage, hexahedral. Streak pale olive-green, ... brown. Hardness = 2.5. Sp. gr. = 2.9, — 3.0.

Description.—Colour green. Occurs regularly crystallized, and massive. Lustre glistening and vitreo-resinous. Translucent, or translucent on the edges.

Geognostic and Geographic Situations.—Occurs in the copper-mines of Cornwall.

Genus III.—OLIVENITE.

Oliven-Malachit, *Mohs.*

Prismatic. Colour or streak neither blue nor bright green. Hardness = 3.0, 4.0. Sp. gr. = 3.6, — 4.6.

1. Prismatic Olivenite, or Prismatic Arseniate of Copper.—Jameson.

Prismatischer Oliven-Malachit, *Mohs.*—Olivenierz, *Werner.*—Cuivre Arseniaté, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P + \epsilon$. (Fig. 30.) Streak olive-green, ... brown. Hardness = 3.0. Sp. gr. = 4.2, — 4.6.

Description.—Principal colour olive-green, also yellow, brown, and white. Occurs regularly crystallized; in concretions which are scopiform fibrous, angular-granular, and curved lamellar; massive and in drusy crusts. Lustre ranges from splendid to glimmering, and is resinous, inclining to pearly, or pearly. Ranges from transparent to opaque.

Geognostic and Geographic Situations.—Occurs in the copper-mines of Cornwall.

2. Diprismatic Olivenite.—Jameson.

Diprismatischer Oliven-Malachit, *Mohs.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage unknown. Streak olive-green. Hardness = 4.0. Sp. gr. = 3.6, — 3.8.

Description.—Colours grass, olive, leek, and pistachio green. Occurs regularly crystallized. Lustre vitreous and pearly. Fracture conchoidal. Ranges from semi-transparent to translucent.

Geognostic and Geographic Situations.—Occurs in drusy cavities in micaceous clay-slate, with quartz and tile-ore; sometimes also with copper pyrites, at Libethen, in Hungary.

Genus IV.—BLUE MALACHITE, or BLUE COPPER.

Lazur Malachit, *Mohs.*

Prismatic. Blue. Hardness = 3.5. — 4. Sp. gr. = 3.5, — 3.7.

1. Prismatic Blue Malachite

Prismatischer Lazur Malachit, *Mohs.*—Kupferlazur, *Werner.*—Cuivre Carbonaté Bleu, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Combination, hemi-prismatic. Cleavage prismatic. Streak blue.

Description.—Colours blue. Occurs regularly crystallized; in concretions which are scopiform and stellular, radiated, and also curved lamellar; massive, globular, botryoidal, reniform, stalactitic, and cellular. Lustre ranges from shining to glimmering, and is vitreo-resinous. Fracture conchoidal. Ranges from transparent to translucent on the edges.

A variety, in dull and fine dusty particles, is named *earthy blue malachite*, while the other varieties are denominated *radiated blue malachite*.

Geognostic and Geographic Situations.—Occurs in mineral veins and in beds in gneiss, mica slate, greywacke, limestone, and red sandstone. It occurs in the Lead Hills, and in various English copper and lead mines.

* Velvet Blue Copper.

Kupfer-ammterz, *Werner.*

Description.—Occurs in bright blue, short capillary crystals. Lustre glistening and silky.

Geognostic and Geographic Situations.—It is a rare mineral; its only known locality is the Bannat, where it is associated with green malachite and brown iron-ore.

Genus V.—EMERALD MALACHITE.

Smaragd-Malachite, *Mohs.*

Hardness = 5.0. Sp. gr. = 3.2, — 3.4.

1. Rhomboidal Emerald Malachite.—Jameson.

Rhomboedrischer Smaragd-Malachit, *Mohs.*—Kupferschmaragd, *Werner.*—Cuivre Diopase, *Haüy.*

Specific Character.—Rhomboidal. Rhomboid = $123^{\circ}58'$. Cleavage rhomboidal. Streak green.

Description.—Colour emerald-green. Occurs regularly crystallized. Internally shining and pearly. Fracture conchoidal. Translucent, passing into semitransparent.

Geognostic and Geographic Situations.—Is a very rare mineral, and has hitherto been found only in the land of the Kirgies in Tartary.

Genus VI.—GREEN MALACHITE.

Habronem-Malachit, *Mohs.*

Prismatic. Colour or streak bright-green. Hardness = 3.5, — 5. Sp. gr. = 3.5, — 4.3.

1. Prismatic Green Malachite, or Phosphat of Copper.—Jameson.

Prismatischer Habronem-Malachit, *Mohs.*—Phospher Kupfererz, *Werner.*—Cuivre Phosphaté, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P + \epsilon$ = 110° (nearly.) (Fig. 30.) Streak emerald-green. Hardness = 5.0. Sp. gr. = 4.0, — 4.3.

Description.—Colours emerald-green, externally with a blackish tarnish, or spotted black. Occurs regularly crystallized; in scopiform fibrous concretions; massive, reniform, botryoidal. Lustre ranges

Mineralogy. from shining to glimmering and is resino-pearly.
Fracture uneven. Opaque.

Geognostic and Geographic Situations.—Occurs at Virneberg, near Rheinbreitenbach, where it is disposed in veins in greywacke.

2. *Diprismatic Green Malachite*, or *Common Malachite*.—Jameson.

Diprismatischer Habronem-Malachit, *Mohs.*—Malachit, *Werner.*—Cuivre Carbonaté Vert, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage, Pr. $P + \infty = 103^\circ$ (nearly). (Fig. 33, 30.) Streak grass or apple green. Hardness = 3.5, ... 4.0. Sp. gr. = 3.5, ... 3.7.

Description.—Colour green. Occurs regularly crystallized; in distinct concretions, which are scopiform, fibrous, angulo granular, and wedge-shaped; also massive, disseminated, tuberoso, stalactitic, reniform, botryoidal, fruticose, and cellular. Lustre ranges from shining to glimmering, and is silky. Fracture uneven, conchoidal, and even. Ranges from translucent to opaque.

Geognostic and Geographic Situations.—Occurs in veins that traverse primitive, transition, and secondary rocks; also in beds, and disseminated through rocks of different kinds. The copper-mine of Sandlodge, in Shetland, formerly afforded fine specimens of the fibrous varieties; and fine masses are sometimes found in the copper-mines of Cornwall.

* ATACAMITE.

Streak leek, ... grass green, 2.5. Sp. gr. = 4.4.

1. *Prismatic Atacamite*, or *Muriat of Copper*.—Jameson.

Cuivre Muriaté, *Haüy.*

Specific Character.—Prismatic. Cleavage very perfectly prismatic.

Description.—Colour green. Occurs regularly crystallized; in radiated and granular concretions; massive, disseminated, and in scaly particles. Lustre shining, glistening, and pearly. Translucent on the edges.

Geognostic and Geographic Situations.—Occurs in veins along with ores of copper in Chili, in the form of grains and scales in alluvial sand in the Desert of Atacama in Peru. Is also found in fissures of some Vesuvian lavas.

Order V.—MICA.

Cleavage monomous and very distinct. Hardness = 1.0, ... 4.5. Sp. gr. = 1.8, ... 5.6.

If metallic lustre, the sp. gr. is under 2.2. If no metallic lustre, the sp. gr. is above 2.2. If the streak is yellow, the sp. gr. is under 3.2.

If the hardness is above 2.5, it is rhomboidal. If the sp. gr. is under 2.5, it is metallic. If above 4.4, the streak is white or grey.

Genus I.—COPPER MICA.

Streak green. Hardness = 2. Sp. gr. = 2.5, ... 2.6.

1. *Rhomboidal Copper Mica*, or *Micaceous Arseniate of Copper*.—Jameson.

Rhomboedrischer Euchlor-glimmer, *Mohs.*—Kupferglimmer, *Werner.*—Cuivre Arseniaté, *Haüy.*

Specific Character.—Rhomboidal. Rhomboid unknown. Cleavage R— ∞ . Streak emerald, ... apple-green.

Description.—Colour green. Occurs regularly crystallized; in granular concretions; massive, and disseminated. Internally splendid and pearly. Fracture uneven. Translucent and transparent. Sectile.

Geognostic and Geographic Situations.—Occurs in the copper-mines of Cornwall.

Genus II.—URAN-MICA, or URANITE.

Streak green, ... yellow. Hardness = 2.0, ... 2.5. Sp. gr. = 3.0, ... 3.2.

1. *Pyramidal Uran Mica*.—Jameson.

Pyramidaler Euchlor-glimmer, *Mohs.*—Uranglimmer, *Werner.*—Uran Oxydé, *Haüy.*

Specific Character.—Pyramidal. Pyramid = $95^\circ 13'$; $144^\circ 56'$. Cleavage, P— ∞ .

Description.—Colours green and yellow. Occurs regularly crystallized; seldom massive, in scales, and in angulo-granular concretions. Lustre ranges from splendid to glistening, and is pearly. Transparent and translucent. Sectile. Not flexible. Easily frangible.

Geognostic and Geographic Situations.—Occurs in the copper and tin-mines of Cornwall.

* *Uran Ochre.*—This is the yellow or reddish coloured, soft, earthy looking, opaque mineral, occasionally associated with uran-mica, and also with uran-ore.

Genus III.—COBALT MICA, or RED COBALT.

Kobalt Glimmer, *Mohs.*

Prismatic. Hardness = 2.5. Sp. gr. = 4.0, ... 4.3.

1. *Prismatic Cobalt Mica*, or *Red Cobalt*.—Jameson.

Prismatischer Kobalt Glimmer, *Mohs.*—Rother Erd Kobalt, *Werner.*—Cobalt Arseniaté, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown.

Combination hemi-prismatic, $\frac{\bar{P}}{2}$ Cleavage, Pr + ∞ .

(Fig. 29.) Streak red, ... green.

Description.—Colours red, rarely grey, green, and brown. Occurs regularly crystallized; in stellular and scopiform fibrous concretions; massive, disseminated, in crusts, reniform, and botryoidal. Lustre ranges from shining to dull, and is pearly and resinous. Fracture earthy and conchoidal. Sectile. Ranges from translucent to opaque.

Geognostic and Geographic Situations.—Occurs in veins in primitive and secondary rocks, and is met with in the coal-field around Edinburgh, and in the old lead-mines of Tyndrum in Perthshire.

* *Cobalt Ochre.*—There are three kinds of this mineral, which we shall now describe.

1. *Black Cobalt Ochre.*—Schwarz Erd Kobalt, *Werner.*

Colours black and occasionally brown. Occurs botryoidal, reniform, and in crusts. Lustre glimmering or dull. Fracture earthy and conchoidal. Opaque. Streak shining and resinous. Very soft, and sometimes friable.

Mineralogy. It is a compound of black oxide of cobalt, with arsenic and oxide of iron.

It occurs at Alderly Edge, Cheshire, in red sandstone.

2. *Brown and Yellow Cobalt Ochre.*—These differ from the preceding principally in colour, the tints being yellow and brown.

Genus IV.—ANTIMONY MICA, or WHITE ANTIMONY.

Antimon-glimmer, *Mohs.*

Hardness = 1.5,—2.0. Sp. gr. = 5.0,—5.6.

1. *Prismatic White Antimony.*—Jameson.

Prismatisches Antimon glimmer, *Mohs.*—Weiss-spieß-glaserz, *Werner.*—Antimoine Oxydè, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage prismatoidal. Streak, white or grey.

Description.—Colours white and grey. Occurs regularly crystallized; in concretions which are scopiform and stellular radiated, and also granular. Lustre shining and pearly-adamantine. Translucent.

Geognostic and Geographic Situations.—It occurs in veins in primitive rocks, along with galena and grey and red antimony, in Bohemia, France, and Hungary.

* *Antimony Ochre.*—Spiesglanzocker, *Werner.*

Colours yellow, brown, and green. Occurs massive, disseminated, and in crusts. Dull. Earthy. Opaque. Very soft.

It always occurs in veins along with grey, and occasionally with red antimony, as in Cornwall.

Genus V.—BLUE IRON, or IRON MICA.

Eisen Glimmer, *Mohs.*

Prismatic. Streak white, grey, ... blue. Hardness = 2.0. Sp. gr. = 2.6.—2.7.

1. *Prismatic Blue Iron, or Phosphat of Iron.*—Jameson.

Prismatisches Eisen Glimmer, *Mohs.*—Vivianit, *Werner.*—Fer Phosphate, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown.

Combination hemiprismatic, $\frac{P}{2}$. Cleavage, $Pr + \infty$.

(Fig. 29.)

Description.—Colours blue and green. Occurs regularly crystallized; in scopiform and promiscuous fibrous concretions; massive, disseminated, and thinly coating. Lustre ranges from splendid to dull, and is pearly, inclining to adamantine. Ranges from transparent to opaque.

It sometimes occurs in a friable, or loosely cohering state, and is then composed of dull dusty particles, forming *earthy blue iron*.

Geognostic and Geographic Situations.—The crystallized varieties are found in Cornwall, those in fibrous concretions in Greenland, and the earthy and friable in our peat mosses.

Genus VI.—GRAPHITE.

Graphite Glimmer, *Mohs.*

Rhombohedral. Hardness = 1.0,—2.0. Sp. gr. = 1.8,—2.1.

1. *Rhombohedral Graphite.*—Jameson.

Rhomboedrischer Graphit-glimmer, *Mohs.*—Gra-phit, *Werner.*—Graphite, *Haüy.*

Specific Character.—Rhombohedral. Rhomboid unknown. Combination dirhombohedral. Cleavage, $R = \infty$. Metallic aspect. Streak black.

Description.—Colour dark steel-grey, inclining to iron-black. Occurs regularly crystallized; in granular concretions; massive and disseminated. Lustre ranges from splendid to glimmering, and is metallic. Fracture scaly foliated, uneven, conchoidal, and slaty. Opaque. Sectile.

Geognostic and Geographic Situations.—It occurs in beds and imbedded masses, in primitive, transition, and secondary rocks. In Scotland it occurs in gneiss, in Glen Strath Farrar, in Inverness-shire; in the coal-formation in Ayrshire; and in England, in transition rocks near Borrodale in Cumberland.

Genus VII.—TALC-MICA.

Talc-Glimmer, *Mohs.*

Rhombohedral. Prismatic. Streak white, grey, green. Hardness = 1.0,—2.5. Sp. gr. = 2.7,—3.0.

1. *Prismatic Talc-Mica, or Talc.*—Jameson.

Prismatischer Talc-glimmer, *Mohs.*

Specific Character.—Prismatic. Pyramid unknown. $P + \infty = 120^\circ$ (nearly.) Cleavage, $P - \infty$. (Fig. 27.) Flexible. Hardness = 1.0,—1.5. Sp. gr. = 2.7,—2.8.

Description.—Colours green, sometimes passing into greenish black, also greenish white, grey, and rarely blue. Occurs regularly crystallized; in granular, fibrous, and prismatic concretions; massive, disseminated, and in amygdaloidal pieces. Lustre ranges from splendid to dull, and is pearly or resinous. Fracture slaty, scaly foliated, earthy, and uneven. Ranges from translucent to opaque.

The dark green varieties, which are generally opaque, are named *chlorite*; of those the regularly crystallized are named *foliated chlorite*; the slaty, *chlorite slate*; the massive, scaly foliated, *common chlorite*; the massive in scaly foliated feebly cohering particles, *earthy chlorite*; and the dull earthy varieties met with in vesicular cavities in amygdaloid, *compact chlorite* or *green earth*. The white and paler green varieties are named *talc*; of these the most translucent, and possessing the highest degree of lustre, are denominated *common talc*; while the grey and green varieties, with slaty fracture and inferior lustre, and inferior translucency, are named *talc slate* or *indurated talc*.

Geognostic and Geographic Situations.—Occurs principally in primitive mountains, sometimes forming whole beds, as is the case with the varieties named *chlorite slate*, and *talc-slate*; other kinds, as *common* and *earthy chlorite*, occur disseminated, in veins, or dispersed through other minerals, as rock crystal, felspar, &c. while the *compact chlorite*, or *green earth*, appears principally in secondary amygdaloid. The most beautiful variety of the species, the *common talc*, occurs only in primitive rocks of limestone, mica slate, &c. Examples of all the varieties are met with in the mountainous districts of Scotland and England.

1. *Native Magnesia, or Hydrate of Magnesia.*—

Mineralogy.

Mineralogy. Colours snow white, greenish white, and also grey. Occurs in prismatic concretions that point to the regular six-sided prism, also in granular concretions, and massive. Cleavage probably rhomboidal. Lustre shining and pearly. Semitransparent in the mass, and transparent in single folia. Streak white, and affords on paper a polished pearly trace. Hardness, 1.5. Slightly elastic. Sp. gr. 2.13, *Brucé*. 2.336, *Brewster*. It is a pure hydrate of magnesia, the proportion of the constituent parts being magnesia 70. Water 30. Occurs in veins in serpentine, in the Shetland Islands and Portsoy.

2. *Ophite*, or Precious Serpentine.—Colours pure leek green, seldomer grass and oil green. Occurs massive and disseminated. Glistening and resinous lustre. Fracture flat conchoidal, inclining to splintery. Translucent, or translucent on the edges. Hardness 3.5. Sp. gr. =2.5,—3.0.

3. *Pikrolite*.—Colour leek green. Massive, and in scopiform fibrous concretions. Lustre glimmering, or dull and silky. Fracture splintery or even. Translucent on the edges. Scratches calc-spar, and is scratched by felspar.

It occurs in small veins in beds of magnetic iron ore, subordinate to gneiss, and also in serpentine, in Sweden.

4. *Nephrite*.—Colours green, grey, and white. Massive, and in rolled pieces. Dull or glimmering. Fracture splintery. Strongly translucent. Difficultly frangible. Hardness =7.0. Sp. gr. =2.9,—3.1.

It occurs imbedded in various primitive rocks in Persia, Egypt, and Germany.

5. *Scatite* or *Soapstone*.—Colours white, red, and yellow, with frequent dendritic markings of black. Occurs massive, in crusts, and in false crystals. Fracture splintery and uneven. Dull or glimmering. Translucent on the edges. Sectile. Soft. Feels very greasy. It occurs principally in serpentine, as in that of the Shetland Islands and Cornwall.

N.B. The *Pimelite* of authors appears to be steatite coloured with nickel or chrome.

6. *Figure-stone* or *Algalmatolite*.—Colours grey, green, white, red, and brown. Massive. Dull or glimmering. Fracture conchoidal, or splintery, and slaty combined. Translucent. Resinous in streak. Feels rather greasy. The finest varieties are brought to Europe from China.

7. *Magnesite*.—Colours white, grey, and cream-yellow. Occurs massive, tuberosc, reniform, vesicular. Dull. Fracture conchoidal. Opaque. Hardness =3.3. Sp. gr. =2.881. Occurs in serpentine in Moravia, and in the Shetland Islands.

8. *Meerschaum*.—Colour white. Massive. Dull. Fracture earthy and conchoidal. Opaque or translucent on the edges. Very soft. Sectile. Adheres strongly to the tongue. Sp. gr. =0.988,—1.279. Occurs in serpentine in Cornwall, Shetland Islands, &c.

9. *Lithomarge*.—Colours white, grey, blue, green, red, and yellow, and these are sometimes disposed in a veined, spotted, clouded or striped manner. Occurs massive, disseminated, globular, and amygdaloid. Dull. Fracture earthy and flat conchoidal. Opaque. Shining in the streak. Soft. Sectile. Adheres strongly to the tongue. Feels fine and greasy. Sp. gr. =2.4.

It occurs in trap, porphyry, and serpentine rocks, in Scotland and other countries.

10. *Mountain Soap*.—Colour blackish-brown. Massive. Dull. Fracture earthy. Opaque. Shining in the streak. Writes. Soft. Sectile. Adheres strongly to the tongue. Feels greasy. Occurs in secondary trap rock, in the Island of Skye.

11. *Bole*.—Colours brown, yellow, red, and black. Sometimes spotted and dendritic. Massive, and disseminated. Lustre glimmering. Fracture conchoidal. Feebly translucent. Soft. Feels greasy. Shining streak. Adheres to the tongue. Sp. gr. =1.922. Occurs imbedded in secondary trap-rocks in Scotland.

2. *Rhomboidal Talk-Mica*, or *Common Mica*.—Jameson.

Rhomboedrischer Talk-glimmer, *Mohs*.

Specific Character.—Rhomboidal. Rhomboid unknown. Combination dirhomboidal. Cleavage, R =∞. Elastic. Hardness =2.0,—2.5. Sp. gr. =2.8,—3.0.

Description.—Colours grey, white, brown, black, red, and blue. Occurs regularly crystallized; in granular and prismatic concretions; massive and disseminated. Lustre ranges from splendid to shining; generally pearly, and sometimes semi-metallic. Fracture coarse, splintery, and scaly foliated. Ranges from transparent to feebly translucent. Sectile. Streak grey and dull.

The red and blue varieties, and which exhibit the splintery and scaly-foliated fractures, are described under the name *Lepidolite*.

Geognostic and Geographic Situations.—It occurs in all the primitive formations, and in most of those belonging to the transition and secondary classes, and therefore is an abundant mineral in this island. The *lepidolite* variety is rare; Dalmally may be mentioned as a British locality.

* *Pimite*.—Colours green, more or less deeply iron-shot. Occurs crystallized in six-sided prisms, in lamellar and granular concretions, and massive. Lustre glistening, glimmering, and resinous. Fracture uneven. Opaque. Soft. Sectile, not flexible. Feels rather greasy. Sp. gr. =2.914. Occurs imbedded in porphyry in Ben Glloe, and other mountains in Scotland.

Genus VIII.—PEARL-MICA.

Perl-glimmer, *Mohs*.

Rhomboidal. Hardness, =3.5,—4.5. Sp. gr. =3.0,—3.1.

1. *Rhomboidal Pearl-Mica*.—Jameson.

Rhomboedrischer Perl-glimmer, *Mohs*.

Specific Character.—Rhomboidal. Rhomboid unknown. Combination dirhomboidal. Cleavage, R =∞. Streak, white or grey.

Order VI.—SPAR.

No metallic lustre. Streak white or grey, . . . and brown. Hardness, =3.5,—7.0. Sp. gr. =2.0,—3.7. If rhomboidal, the sp. gr. =2.2, and less, or the hardness =6.0. If hardness =4.0, the clea-

Mineralogy. vage is montomous. If hardness above 6.0, the sp. gr. is under 2.5, or above 2.8; and the lustre is pearly. If sp. gr. above 3.3, the combination is hemi or tetarto-prismatic, or the hardness = 6.0; and no adamantine lustre. If sp. gr. = 2.4, and less, there are traces of form and cleavage.

Genus I.—SCHILLER-SPAR.

Schiller-Spath, *Mohs*.

Prismatic. Cleavage montomous. Hardness = 3.6, —6.0. Sp. gr. = 3.6, —3.4. If hardness = 6.0, the lustre is metallic-pearly.

1. *Diatomous*, * or *Common Schiller-Spar*.—Jameson.

Diatomer Schiller-spath, *Mohs*.—Schiller-stein, *Werner*.—Diallage Metalloide, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage prismatic. Metallic pearly lustre. Hardness = 3.5, —4.0. Sp. gr. = 2.6, —2.8.

Description.—Colours green, grey, and brown. Occurs in granular concretions; disseminated, and seldom massive. Lustre shining or splendid, and metallic-pearly. Translucent on the edges, or opaque. Dull streak.

Geognostic and Geographic Situations.—Occurs imbedded in serpentine in the Shetland Islands, and in secondary trap-rocks in the middle district of Scotland.

2. *Axotomous* † *Schiller-Spar*, or *Green Diallage*.—Jameson.

Axentheiler Schiller-spath, *Mohs*.—Korniger Strahlstein, *Werner*.—Diallage Verte, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P = \infty$. (Fig. 27.) Common pearly lustre. Hardness = 4.5, —5.5. Sp. gr. = 3.0, —3.2.

Description.—Colour green; massive and disseminated. Internally shining and glistening. Translucent on the edges, or translucent.

Geognostic and Geographic Situations.—Occurs in primitive rocks in Shetland Islands, and Mainland of Scotland.

3. *Hemi-prismatic Schiller-Spar*, or *Bronzite*.—Jameson.

Hemiprismatischer Schiller-Spath, *Mohs*.—Blättriger Anthophyllit, *Werner*.—Diallage Metalloide, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Combination hemiprismatic. Cleavage,

P . $Pr = \infty$. Less perfect, $\frac{Pr}{2}$. $Pr = \infty$. (Fig. 29, 35, 28.) Lustre metallic-pearly. Hardness = 4.0, —5.0. Sp. gr. = 3.0, —3.3.

Description.—Colours brown and grey. Occurs in granular concretions. Lustre shining. Cleavage

Mineralogy. sometimes appears fibrous. Translucent on the edges. Streak white.

Geognostic and Geographic Situations.—Occurs in serpentine in Shetland; in greenstone in the Island of Skye, and near Portsoy; and in other parts of Scotland.

4. *Prismatoid Schiller-Spar*, or *Hypersthene*.—Jameson.

Prismatoidischer Schiller-Spath, *Mohs*.—Paulit, *Werner*.—Hypersthene, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $Pr = \infty$. Less perfect, $P + \alpha = 100$ (nearly). $Pr + \alpha$. (Fig. 29, 30, 28.) Lustre metallic-pearly. Hardness = 6.0. Sp. gr. = 3.3, —3.4.

Description.—Colours greenish and greyish black; also copper-red and brown. Occurs in granular and lamellar concretions, and massive. Lustre shining. Opaque or feebly translucent.

Geognostic and Geographic Situations.—Occurs in greenstone in the Island of Skye; also in Banffshire and the Shetland Islands.

5. *Prismatic Schiller-Spar*, or *Anthophyllite*.—Jameson.

Prismatischer Schiller-Spath, *Mohs*.—Strahliger Anthophyllit, *Werner*.—Anthophyllite, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $Pr = \infty$. Rather less perfect, $P + \alpha = 106^\circ$ (nearly). $Pr + \alpha$. (Fig. 28, 30, 29.) Lustre almost metallic-pearly. Hardness = 5.0—5.5. Sp. gr. = 3.0, —3.3.

Description.—Colours yellowish grey and yellowish brown. Occurs crystallized in reed-like crystals; in scopiform and promiscuous radiated concretions, also massive. Translucent on the edges.

Geognostic and Geographic Situations.—Occurs in primitive rocks, near Drumnadrochit, in Inverness-shire.

Genus II.—KYANITE.

Disthen Spath, *Mohs*.

Prismatic. Hardness = 5.0, —7.0. Sp. gr. = 3.6, —3.7.

1. *Prismatic Kyanite*.—Jameson.

Disthen Spath, *Mohs*.—Kyanite and Rhatizit, *Werner*.—Disthene, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Combination, tetarto-prismatic. Cleavage, two faces, the one more distinct than the other. Incidence = $102^\circ 50'$.

Description.—Colours blue and bluish green. Occurs regularly crystallized; in distinct concretions, which are granular and radiated, which latter are sometimes scopiform and stellular; also massive and

* From *δια*, through; and *τεμνω*, I cut; easily cleavable in one direction.

† From *αξων*, the axis; and *τεμνω*, I cut; cleavable perpendicular to the axis.

Mineralogy. disseminated. Lustre splendid and pearly. Translucent and transparent.

Geognostic and Geographic Situations.—It occurs in primitive rocks in the Shetland Islands; also in Banffshire and Aberdeenshire.

Genus III.—SPODUMENE.

Hardness = 6.5, —7.0. Sp. gr. = 3.0, —3.1.

1. *Prismatic Spodumene*.—Jameson.

Spodumen, Werner.—Triphane, Haüy.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P+\infty=100^\circ$ (nearly). Somewhat more distinct, P_r+8 . Not blue. (Fig. 30, 29.)

Description.—Colours greenish white and green. Occurs massive, and in large granular concretions. Lustre shining, glistening, and pearly. Fracture uneven. Translucent. Uncommonly easily frangible.

Geognostic and Geographic Situations.—Occurs in primitive rocks in Sweden and in Ireland.

Genus IV.—PREHNITE.

Axotomer Triphan-Spath, Mohs.—Prehnite, Werner and Haüy.

Hardness = 6, —7. Sp. gr. = 2.8, —3.0. Not blue.

1. *Axotomous Prehnite*.—Jameson.

Specific Character.—Prismatic. Pyramid unknown. Cleavage $P+\infty=103^\circ$ (nearly). More distinct $P-\infty$. (Fig. 30, 27.)

Description.—Colours green, grey, and white. Occurs crystallized; in granular and in scopiform and stellular fibrous distinct concretions; massive and reniform. Lustre shining, glistening, and pearly. Fracture uneven. Ranges from transparent to translucent.

Geognostic and Geographic Situations.—The more highly crystallized varieties have hitherto been found principally in primitive rocks, while the fibrous or less perfectly crystallized varieties occur principally in secondary trap-rocks. The secondary trap-rocks of Scotland afford many localities of this mineral.

• *Karpholite*.—The colour of this rare mineral is yellow. It occurs in fine prismatic concretions. Its hardness is unknown, but its sp. gr. = 2.935. It has hitherto been found only at Schlackenwalde in Bohemia.

Genus V.—DATOLITE.

Dystom-Spath, Mohs.

Prismatic. Internally, lustre resinous. Colour not blue. Hardness = 5.0, —5.5. Sp. gr. = 2.9, —3.0.

1. *Prismatic Datolite*.—Jameson.

Prismatischer Dystom-Spath, Mohs.—Chaux Boratée Siliceuse, Haüy.

Specific Character.—Prismatic. Pyramid = $129^\circ 1'$; $105^\circ 2'$; $69^\circ 23'$. Combination hemiprismatic. $P = 129^\circ 1'$. Cleavage, $P+\infty=109^\circ 28'$ imperfect. (Fig. 30.)

Description.—Most frequent colours white and grey, seldom red, green, and yellow. Occurs regularly crystallized; in granular, scopiform, and stellular, fibrous, and curved lamellar concretions; massive, reniform, and botryoidal. Lustre ranges from shining to dull, and is resinous or pearly. Fracture conchoidal, uneven, and earthy. Ranges from transparent to opaque.

The reniform and botryoidal varieties in fibrous concretions are named *Botryolite*; the earthy-looking and botryoidal *Earthy Botryoidal Datolite*; all the others *Common Datolite*.

Geognostic and Geographic Situations.—Occurs in beds of magnetic iron-ore, subordinate to gneiss, near Arendal in Norway, and rarely in other parts of Europe.

Genus VI.—ZEOLITE.

Kouphon-Spath, Mohs.

Tessular, rhomboidal, pyramidal, prismatic. Hardness = 3.5, —6.0. Sp. gr. = 2.0—2.5. If the most distinct cleavage be parallel to a rectangular prism, the sp. gr. = 2.4, and less.

1. *Trapezoidal Zeolite, or Leucite*.—Jameson.

Trapezoidaler Kuphon-Spath, Mohs.—Leuzit, Werner.—Amphigène, Haüy.

Specific Character.—Tessular. Cleavage hexahedral, dodecahedral, imperfect. Hardness = 5.5, —6.0. Sp. gr. = 2.4, —2.5.

Description.—Colours white and grey. Occurs regularly crystallized; in granular concretions, and in roundish grains. Lustre shining or glistening, and vitreo-resinous. Fracture flat conchoidal. Ranges from transparent to opaque.

Geognostic and Geographic Situations.—Occurs in imbedded grains and crystals in older lavas, and associated with garnet, hornblende, quartz, glassy felspar, in the ejected masses of Monte Somma, and the extinct volcanoes on the Rhine, afford examples of leucite in both situations.

2. *Dodecahedral Zeolite, or Sodalite*.—Jameson.

Dodecaedrischer Kuphon-Spath, Mohs.—Sodalite, Thomson.

Specific Character.—Tessular. Cleavage dodecahedral, and perfect. Hardness = 5.5, —6.0. Sp. gr. = 2.2, —2.4.

Description.—Colour green. Occurs in rhomboidal dodecahedrons, and massive. Lustre shining or glistening, and vitreo-resinous. Fracture conchoidal. Translucent.

Geognostic and Geographic Situations.—Occurs in mica-slate in West Greenland.

3. *Hexahedral Zeolite, or Analcime*.—Jameson.

Hexaedrischer Kuphon-Spath, Mohs.—Analcime, Haüy.—Kubizit, Werner.

Specific Character.—Tessular. Cleavage hexahedral, imperfect. Hardness = 5.5. Sp. gr. = 2.0, —2.2.

Description.—Colours white and red. Occurs regularly crystallized; in angulo-granular concretions, and massive. Lustre shining, glistening and vitreo-pearly. Fracture uneven, or conchoidal. Ranges from transparent to translucent.

Mineralogy. *Geognostic and Geographic Situations.*—Occurs in secondary greenstone rocks in Fifeshire, Salisbury Crag, near Edinburgh, and in the same rock in many other parts of Scotland.

4. *Paratomous Zeolite, or Cross-stone.*—Jameson.

Paratomer Kuphon-spath, *Mohs.*—Kreutzstein, *Werner*—Harmotome, *Hauy*

Specific Character.—Prismatic. Pyramid unknown.

Cleavage $P. Pr + \infty. Pr + \infty.$ (Fig. 29, 28.) Hardness = 4.5. Sp. gr. = 2.3, —2.4.

Description.—Colours white and grey, sometimes also yellow and red. Most frequently in regular crystals, seldom massive. Lustre shining, glistening, and vitreo-pearly. Fracture conchoidal and uneven. Translucent.

Geognostic and Geographic Situations.—Occurs in galena veins in the mines of Strontian in Argyleshire, and in secondary trap-rocks in Dumbartonshire, and other parts of Scotland.

5. *Rhomboidal Zeolite, or Chabasite.*—Jameson.

Rhomboedrischer Kuphon-Spath, *Mohs.*—Chabasie, *Hauy*.—Schabasit, *Werner*.

Specific Character.—Rhomboidal. Rhomboid, = $93^\circ 48'$. Cleavage rhomboidal. Hardness = 4.0, —4.5. Sp. gr. = 2.0, —2.1.

Description.—Colour white. Occurs regularly crystallized, seldom massive. Externally splendent, internally glistening and vitreous. Fracture conchoidal and uneven. Translucent.

Geognostic and Geographic Situations.—Occurs in various secondary trap-rocks, especially amygdaloid, and is not unfrequent in the trap-rocks of Scotland.

6. *Diatomous Zeolite, or Laumonite.*—Jameson.

Diatomer Kuphon-spath, *Mohs.*—Laumonite, *Werner*, *Hauy*.

Specific Character.—Prismatic. Pyramid = $129^\circ 7'$; $120^\circ 48'$; $81^\circ 6'$. $P + \infty = 98^\circ 13'$. Combination hemi-prismatic, $\frac{P}{2} = 120^\circ 48'$. Cleavage,

$Pr + \infty.$ More perfect, $Pr + \infty.$ (Fig. 28, 29.) Hardness unknown. Sp. gr. = 2.3, —2.4.

Description.—Colour white. Occurs regularly crystallized, and in granular distinct concretions. Lustre shining, glistening, and pearly. When fresh is transparent; but on exposure to the atmosphere it very soon becomes opaque, and so soft as to yield to the pressure of the finger. Uncommonly easily frangible.

Geognostic and Geographic Situations.—This mineral occurs in secondary trap-rocks in various parts of Scotland and Ireland.

7. *Prismatic Zeolite, or Mesotype.*—Jameson.

Prismatischer Kuphon-spath, *Mohs.*—Mesotype, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P + \infty = 91^\circ 25'$. (Fig. 30.) Hardness = 5.0, —5.5. Sp. gr. = 2.0, —2.3.

Description.—Colours white, red, yellow, and yellowish-brown. Occurs regularly crystallized; in distinct concretions which are scopiform and stellar

fibrous, granular, and curved lamellar; reniform, coralloidal, in plates and crusts. Lustre ranging from shining to dull, and is pearly. Fracture, in some varieties, coarse earthy. Ranges from nearly transparent to opaque.

The yellow and brown varieties, with striped colour delineations, and in which the fibrous and granular concretions are intersected by lamellar, are named *Natrolite*; those with earthy fracture and very soft, *Pearly zeolite*; while the other varieties are named *Fibrous zeolite*.

Geognostic and Geographic Situations.—Occurs principally in drusy cavities, or in veins in secondary trap-rocks in many places in Scotland. The natrolite is the rarest variety in Scotland.

8. *Prismatoid Zeolite, or Stilbite.*—Jameson.

Prismatoidischer Kuphon-spath, *Mohs.*—Stilbit, *Hauy*.—Strahl-zeolith, *Werner*.

Specific Character.—Prismatic. Pyramid = $123^\circ 33'$; $112^\circ 16'$; $93^\circ 7'$. $P + \infty = 89^\circ 22'$. Cleavage, $Pr + \infty$, very perfect. (Fig. 29.) Hardness = 3.5, —4.0. Sp. gr. = 2.0, —2.2.

Description.—Colour white, sometimes grey, yellow, and red. Occurs regularly crystallized; in granular, and in scopiform, and stellar prismatic concretions; also massive and globular. Externally splendent. Internally shining and pearly. Alternates from transparent to translucent.

Geognostic and Geographic Situations.—Occurs abundantly in secondary trap-rocks in many districts in Scotland.

9. *Hemi-prismatic Zeolite.*—Jameson.

Hemi-prismatischer Kuphon-spath, *Mohs.* Blätter Zeolith, *Werner*. Stilbite, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown. Combination, hemiprismatic $\frac{P}{2}$. Cleavage, $Pr + \infty$, very perfect. (Fig. 29.) Hardness = 3.5, —4.0. Sp. gr. = 2.0, —2.2.

Description.—Colours white, grey, red, and brown. Occurs regularly crystallized; in granular and lamellar distinct concretions. Fracture conchoidal. Externally, lustre splendent, shining, and vitreous; internally, shining and pearly. Ranges from transparent to translucent on the edges.

Geognostic and Geographic Situations.—Occurs in drusy cavities in secondary trap-rocks in the Hebrides and Mainland of Scotland.

10. *Pyramidal Zeolite, or Apophyllite.*—Jameson.

Pyramidaler Kuphon-spath, *Mohs.* Albin, *Werner*. Mesotype épointée, *Hauy*.

Specific Character.—Pyramidal. Pyramid unknown. Cleavage, $P - \infty$, very perfect. [$P + \infty$] imperfect. Hardness = 4.5, —5.0. Sp. gr. = 2.2, —2.5.

Description.—Colour white. Occurs regularly crystallized; in straight and curved lamellar distinct concretions; massive and disseminated. Surface of the cleavage strongly iridescent. Externally splendent, but only the terminal planes of the prism pearly.

Mineralogy. ly; internally glistening and vitreous. Ranges from transparent to translucent.

Geognostic and Geographic Situations.—Occurs in secondary trap-rocks in the Hebrides and other parts of Scotland.

11. *Axotomous Zeolite*, or *Ichthyophthalmite*.

Axotomer Kuphon-spath, *Mohs*. Ichthyophthalm, *Werner*. Apophyllite, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P=\infty$, very distinct. Less distinct $Pr+\infty$. $Pr+\infty$. (Fig. 27, 29, 28.) Hardness = 4.5, —5.0. Sp. gr. = 2.2, —2.5.

Geognostic and Geographic Situations.—Occurs in secondary trap-rocks in Scotland.

Genus VI.—PETALITE.

Petalin-spath, *Mohs*.

Prismatic. Hardness = 6.0, —6.5. Sp. gr. = 2.4, —2.5.

1. *Prismatic Petalite*.—Jameson.

Prismatischer Petalin-spath, *Mohs*.

Specific Character.—Prismatic. Pyramid unknown.

Cleavage, $P+\infty=137^{\circ} 8'$. $Pr+\infty$.

Description.—Colours red and white. Occurs massive; internally glistening, shining, and nearly pearly. Translucent. Brittle, and rather easily frangible.

Geognostic and Geographic Situations.—It has hitherto been found only in the island of Uton in Sudermania, in large masses, containing spodumene, felspar, quartz, mica, tourmaline, and ores of iron, arsenic, and silver.

Genus VII.—FELSPAR.

Rhomboidal, pyramidal, prismatic. Cleavage not very perfect. Axotomous. Hardness = 5.0, —6.0. Sp. gr. = 2.5, —2.8. If Sp. gr. = 2.7, and more, the cleavage planes are perpendicular to each other.

1. *Rhomboidal Felspar*, or *Nepheline*.—Jameson.

Rhomboedrischer feldspath, *Mohs*. Nepheline, *Haüy* and *Werner*.

Specific Character.—Rhomboidal. $R=131^{\circ} 49'$. Combination, di-rhomboidal. $2(R)=152^{\circ} 44'$; $56^{\circ} 15'$. Cleavage, $R=\infty$. $R+\infty$. Hardness = 6.0. Sp. gr. = 2.5, —2.6.

Description.—Colours white and grey. Occurs regularly crystallized, and massive. Externally splendid, internally shining and vitreous. Fracture conchoidal. Translucent, passing into transparent.

Geognostic and Geographic Situations.—Occurs in drusy cavities in granular foliated limestone, with meionite, Vesuvian, pleonaste, rhomboidal garnet, mica, &c. in the ejected masses on Monte Somma, near Naples.

2. *Prismatic Felspar*, or *Common Felspar*.—Jameson.

Prismatischer Feldspath, *Mohs*.

Prismatic. Pyramid = $134^{\circ} 26'$; $126^{\circ} 52'$; $72^{\circ} 32'$. $P+\infty=81^{\circ} 47'$. Combination $\frac{P}{\infty}=126^{\circ} 52'$.

Cleavage, $\frac{Pr}{2}$. $Pr+\infty$. Both very perfect. Less

Mineralogy.

distinct, $(Pr+\infty)^2=120^{\circ}$. Sometimes only one of the faces. (Fig. 44.) Hardness = 6.0. Sp. gr. = 2.5, —2.8.

Description.—Colours white, grey, green, blue, red, and brown; and sometimes with pearly opalescence, and beautiful changeability of colour. Occurs regularly crystallized; in distinct concretions, which are angulo-granular and lamellar; massive and disseminated. Lustre ranges from splendid to glistening, and even to dull, and is vitreo-pearly, or vitreous. Fracture conchoidal, splintery, slaty, and earthy. Ranges from transparent to opaque.

The transparent and translucent white-coloured varieties, with the silvery or pearly opalescence, are named *adularia*; the white and grey transparent varieties usually in small crystals, which are traversed by numerous rents, are named *glassy felspar*; the translucent varieties, with various shades of colour, such as white and red, and rarely blue and green, are the most abundant, and hence are named *common felspar*; the dark-grey varieties, with the beautiful changeability of colour, are named *Labrador felspar*, from the country where they were first found; the feebly translucent compact varieties, with splintery fracture, are named *compact felspar*; the slaty varieties, with feeble lustre and translucency, are named *slaty felspar* or *clinkstone*; the varieties, in a comparatively loose state of aggregation, and without lustre and transparency, according to their degrees of compactness, are named *porcelain earth*, *earthy felspar*, and *claystone*.

Geognostic and Geographic Situations.—Felspar is one of the most abundant minerals in nature, as it occurs in most of the principal rock formations. It abounds in the Alpine districts of Scotland, England, and Ireland, in granite, syenite, gneiss, porphyry, trap, and quartz rocks.

3. *Pyramidal Felspar*, or *Scapolite*.—Jameson

Pyramidaler Feldspath, *Mohs*.—Meionite, Scapolith, Schmelzstein, *Werner*.—Paranthine, Meionite, *Wernerite*, *Dipyre*, *Haüy*.

Specific Character.—Pyramidal. Pyramid = $136^{\circ} 7'$; $63^{\circ} 48'$. Cleavage, $P=\infty$. More perfect, $P+\infty$. $[P+\infty]$. Hardness = 5.0, —5.5. Sp. gr. = 2.5, —2.8.

Description.—Colours white, grey, green, red, and black. Occurs regularly crystallized; in distinct concretions, which are scopiform, fibrous, or radiated, and angulo-granular; massive and disseminated. Lustre ranges from splendid to glimmering, and is pearly, resino-vitreous, and resino-pearly. Fracture conchoidal, uneven. Ranges from transparent to opaque.

The white and more transparent and highly crystallized varieties are named *Meionite*, while the others have received the names *Scapolite*, *Paranthine*, *Wernerite*, *Dipyre*, and *Schmelzstein*.

Geognostic and Geographic Situations.—The meionite varieties are found in drusy cavities in granular foliated limestone, along with nepheline, augite, mica, pleonaste, garnet, and calcareous spar, on

Mineralogy. Monte Somma, near Naples; the scapolite varieties occur in beds of magnetic ironstone and iron pyrites, in gneiss, along with quartz, felspar, mica, hornblende, epidote, garnet, augite, &c. at Arendal, in Norway; also in Sweden, Finland, Saxony, Pyrenees, &c.

* *Eläolite*.—Muschlicher Wernerite, Feltstein, Werner. Lythodes, Karsten. Purre grasse, Haüy.

Specific Character.—Prismatic. Cleavage, $P = \infty$. $Pr + \infty$. Less distinct, $P + \infty$. Hardness, = 5.5, —6.0. Sp. gr. = 2.546, —2.618.

Description.—Colours muddy flesh-red and greenish-grey, inclining to blue. Occurs massive. Lustre glistening and resinous. Fracture flat conchoidal, inclining to splintery and uneven. Translucent.

Geognostic and Geographic Situations.—Occurs imbedded in syenite, along with titanite, zircon, and molybdena, at Laurwig, and Friedrichsivarn, in Norway.

Genus VIII.—Augite.

Prismatic. Lustre not metallic-pearly. Hardness = 4.5, —7.0. Sp. gr. = 2.7, —3.5. If the hardness is above 6.0, the sp. gr. = 3.2, and more. If the sp. gr. is under 3.0, the cleavage is very perfect, and in the direction of oblique-angular prisms.

1. *Paratomous Augite*.—Jameson.

Paratome Augit, Mohs.—Augit, Werner.—Pyroxene, Haüy.

Specific Character.—Prismatic. Pyramid = $152^\circ 12'$; 120° ; $61^\circ 2'$. $P + \infty = 51^\circ 19'$. Combination hemi-prismatic. $\frac{P}{2} = 120^\circ$. Cleavage, $(Pr + \infty)^3 =$

$87^\circ 12'$, $Pr + \infty$. $Pr + \infty$. Sometimes $\frac{P}{2}$. (Fig. 32, 29, 28, 38.) Hardness = 5.0, —6.0. Sp. gr. = 3.2, —3.5.

Description.—Colours green, black, and brown; also grey and white. Occurs regularly crystallized; in granular and fibrous concretions; massive and disseminated. Lustre ranges from splendent to glimmering, and is vitreo-resinous, resino-pearly, and resinous. Fracture conchoidal and uneven. Ranges from transparent to translucent on the edges.

Those varieties in which the colours are white and pale green, generally crystallized, with a vitreous external, and pearly internal lustre, and translucent, are named *Diopside*, *Musite*, *Alalite*, and by some *Baikalite*; those, again, in which the colours are darker green and muddy grey, less frequently crystallized, but disposed in straight, lamellar, and granular concretions, with a shining, vitreous, or pearly lustre, and translucent on the edges, are named *Sahlite*, *Pyrogome*, *Fassaite*, *Malacolite*, and by some *Baikalite*; other varieties, in which the colours are black and dark green, with conchoidal and uneven fracture, resinous lustre, and opaque or faintly translucent on the edges, are named *Conchoidal Augite* and *Common Augite*; those varieties in which the colours are principally leek-green and greenish-black, generally in loosely aggregated angulo-granular concretions, with a shining vitreo-resinous lustre,

uneven fracture, and ranging from translucent to opaque, are named *Coccolite* and *Granular Augite*; and, lastly, the fibrous varieties have been described as *Amianthus*.

Geognostic and Geographic Situations.—The diopside varieties are found imbedded in serpentine, and associated with magnetic iron-ore in Piedmont; the sahlite in beds of primitive trap, limestone, and magnetic iron-ore, subordinate to gneiss and mica slate in Scotland, Ireland, and Scandinavia; the conchoidal augite and common augite occur principally in secondary trap rocks; and the coccolite and granular augite in the iron mines of Arendal, in Norway, in gneiss.

2. *Hemi-prismatic Augite*, or *Hornblende*.—Jameson.

Hemi-prismatischer Augit-spath, Mohs.—Hornblende, &c. Werner.—Amphibole, Haüy.

Specific Character.—Prismatic. Pyramid = $151^\circ 8'$; $148^\circ 39'$; $42^\circ 22'$. $P + \infty = 87^\circ 11'$. Combination, hemi-prismatic, $\frac{P}{2} = 148^\circ 39'$. Cleavage,

$(Pr + \infty)^3 = 124^\circ 34'$. Less distinct, $Pr + \infty$. $Pr + \infty$. (Fig. 32, 29, 28.) Hardness = 5.0, —6.0. Sp. gr. = 2.7, —3.2.

Description.—Colours green, white, black, grey, blue, and brown. Occurs regularly crystallized; in fibrous, radiated, and granular distinct concretions. Lustre ranges from splendent to feebly glimmering, and lustre vitreo-pearly, pearly, or vitreous, and vitreo-resinous. Fracture conchoidal, uneven, and slaty. Alternates from transparent to opaque.

The varieties with dark green and black colours, in granular and fibrous concretions, and in which the lustre ranges from splendent to shining, and is pearly or pearly-vitreous, and the transparency from transparent to translucent on the edges, are named *Hornblende* and *Carinthine*; the varieties with light green, and also greenish-grey, and sometimes brown and yellow colours, rarely crystallized (and then generally in reed-like crystals), more frequently massive, and in radiated, fibrous, and granular concretions, with a pearly or vitreous, splendent, shining, or glistening lustre, and transparency varying from transparent to opaque, are named *Actynolite* and *Calamite*; the white and blue varieties, disposed in fibrous, radiated, and granular concretions, with a lustre which is shining, or glistening and pearly, or vitreo-pearly, and ranging from translucent to translucent on the edges, are named *Tremolite*; other varieties, in which the colours are white, green, yellow, blue, and brown, and disposed in flexible, shining, silky, fibrous concretions, are named *Flexible Asbestos*, or *Amianthus*; others, which are of a white colour, or grey colour, and disposed in minute promiscuous fibrous concretions, and so light as to swim in masses in water, are named *Mountain Cork*; those in which the colours are generally green, and disposed in straight, shining, pearly, rigid, fibrous concretions, are named *Rigid*, or *Common Asbestos*; and, lastly, those varieties in which the colour is wood-brown, and in general aspect much resembling fossil wood, are named *Rock-wood*, or *Ligneous Asbestos*.

Mineralogy.

Geognostic and Geographic Situations.—The hornblende varieties abound in primitive and transition rocks, and are also met with in those of the secondary class; those named actinolite and tremolite scarcely occur in secondary rocks, being confined principally to those of the primitive class; while the asbestine varieties are principally met with in the serpentine rocks of primitive and transition mountains. Numerous localities of this species occur in Scotland, England, and Ireland.

3. *Prismatoidal Augite, or Epidote.*—Jameson.

Prismatoidischer Augit-spath, *Mohs.*—Epidote, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Combination hemi-prismatic. Cleavage, two faces, of which one is more distinct than the other. Incidence = $114^{\circ} 37'$. Hardness = 6.0, —7.0. Sp. gr. = 3.2, —3.5.

Description.—Colours green and grey. Occurs regularly crystallized; in granular, fibrous, and prismatic concretions. Lustre ranges from splendid to glimmering, and is resinous-pearly. Fracture conchoidal, uneven, splintery, and sometimes nearly earthy. Ranges from transparent to translucent on the edges. Brittle, and easily frangible.

The green varieties are named simply epidote, or *pistacite*; while the grey and less perfectly crystallized varieties are named *zoisite*.

Geognostic and Geographic Situations.—It occurs principally in primitive rocks, such as gneiss, mica-slate, syenite, &c. Inverness-shire, Ross-shire, the Shetland Islands, and other parts of Scotland, afford many varieties of it.

4. *Prismatic Augite, or Tabular-Spar.*—Jameson.

Prismatischer Augit spath, *Mohs.*—Schaalstein, *Werner.*—Spath en Tables, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown.

Cleavage, $P + \infty = 105^{\circ}$ (nearly). $Pr + \infty$. $Pr + \infty$. Sp. gr. = 2.7, —2.9.

Description.—Colour white. Occurs in granular and lamellar concretions; also massive and disseminated. Lustre ranges from shining to glistering, and is pearly-vitreous. Fracture splintery. Translucent. Brittle.

Geognostic and Geographic Situations.—Occurs in primitive rocks in the Bannat, and in rocks of the same description in the island of Ceylon.

Genus IX.—AZURE-SPAR.

Colour blue. Hardness = 5.0, —6.0. Sp. gr. = 3.0, —3.1.

1. *Prismatic Azure-Spar.*—Jameson.

Lazulit, *Werner.*—Lazulite, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage $P + \infty$. (Fig. 30.) Colour lively. Hardness = 5.0, —5.5.

Description.—Colour blue. Occurs massive. Fracture uneven. Opaque. Very feebly translucent on the edges. Easily frangible.

Geognostic and Geographic Situations.—Occurs

imbedded in quartz, in the district of Vorau, in *Mineralogy.* Styria.

2. *Prismatoidal Azure-Spar.*—Jameson.

Blauspath, *Werner.*—Feldspath, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage prismatoidal. Colour pale. Hardness = 5.5, —6.0.

Description.—Colour blue. Occurs massive and disseminated. Lustre glistening. Fracture splintery. Feebly translucent. Yields a greyish-white streak.

Geognostic and Geographic Situations.—Occurs in primitive rocks in Styria.

• 1. *Azure-Stone, or Lapis Lazuli.*

Lazurstein, *Werner.*

Tessular. Form dodecahedral. Cleavage unknown, imperfect. Azure blue. Hardness = 5.5, —6.0. Sp. gr. = 2.767, —2.959.

Colour blue. Occurs massive, with disseminated marble and iron pyrites. Lustre glistening and glimmering. Fracture uneven. Feebly translucent on the edges.

Geognostic and Geographic Situations.—Occurs in rocks of limestone in Persia and China.

2. *Haüyne-Lazulite.*—Haüy.

Prismatic. Cleavage P . More distinct $P - \infty$, Blue. Scratches glass. Sp. gr. = 2.687, *Gmelin.* 3.333, *Gismondi.*

3. *Calaité or Mineral Turquoise.*

Form unknown. Massive. Blue...green. Streak white. Hardness = 6. Sp. gr. = 2.830...3.0.

4. *Amblygonite.*—Breithaupt and *Mohs.*

Prismatic. $P + \infty = 106^{\circ} 10'$. Cleavage, $P + \infty$. Hardness = 6. Sp. gr. = 3.0.

5. *Diaspore.* Diaspore.—*Haüy and Mohs.*

Prismatic. Cleavage, $P + \infty = 130^{\circ}$ nearly. More distinct $Pr + \infty$. Scratches glass. Sp. gr. = 3.433.

6. *Gehlenite.* Gehlenit.—*Mohs and Haüy.*

Pyramidal, or prismatic. Cleavage unknown, or very imperfect. Hardness = 5.5. —6. Sp. gr. = 2.0, —3.1.

Order VII.—GEM.

No metallic lustre. Streak white or grey. Hardness = 5.5, —10.0. Sp. gr. = 1.9, —4.7. If hardness = 6.0, and less, the sp. gr. = 2.4, and less, and no traces of form or cleavage. If sp. gr. is less than 3.8, there is no pearly lustre.

Genus I.—ANDALUSITE.

Prismatic. Cleavage, not prismatoidal. Hardness = 7.5. Sp. gr. = 3.0, —3.2.

1. *Prismatic Andalusite.*—Jameson.

Prismatischer Andalusit, *Mohs.*—Andalusit, *Werner.*—Feldspath apyre, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P + \infty$. $Pr + \infty$. $Pr + \infty$. (Fig. 30, 29, 28.)

Description.—Colours red and grey. Occurs re-

Mineralogy. gularly crystallized and massive. Lustre shining, glistening, and vitreous. Fracture uneven. Feebly translucent.

Geognostic and Geographic Situations.—Occurs in gneiss in Shetland Islands, and in Aberdeenshire.

* *Fibrolite.*—Bournon.

Prismatic. $P + \infty = 100^\circ$. Cleavage imperfect. Hardness more considerable than quartz, and sp. gr. = 3.214. Occurs in the Carnatic.

* *Chiasolite.* Hohlspath, Werner.—Macle, Haüy.

Prismatic. $P + \infty = 84^\circ 48'$. $Pr = 120$ nearly. Cleavage, $P - \infty$. $Pr + \infty$. $Pr - \infty$. All of them imperfect. Hardness = 5, — 5.5. Sp. gr. = 2.9, — 3.0. Occurs in clay-slate near Keswick in Cumberland, and near Balahulish in Argyllshire.

Genus II.—CORUNDUM.

Tessular, rhomboidal, prismatic. Hardness = 8.0. — 9.0. Sp. gr. = 3.5, — 4.3. If prismatic, the sp. gr. = 3.7, and more, and hardness = 8.5. If colour red, and sp. gr. = 3.7, and more, the hardness = 9.0.

1. Dodecahedral Corundum.—Jameson.

Dodecaedrischer Corund, Mohs.—Spinel and Zeilanit, Werner.—Spinelle, Haüy.

Specific Character.—Tessular. Cleavage, octahedral, but obtained with difficulty. Hardness = 8.0. Sp. gr. 3.5, — 3.8.

Description.—Colours red, and sometimes green, black, blue, yellow, brown, and white. Occurs regularly crystallized. Lustre splendid and vitreous. Fracture conchoidal. Ranges from transparent to translucent on the edges.

The dark green and black varieties, which are only translucent on the edges, are named *ceylanite*; and all the others *spinel* or *spinel-ruby*.

Geognostic and Geographic Situations.—The ceylanite varieties occur in the sand of rivers in Ceylon; the others also in Ceylon, Pegu, and other countries.

2. Octahedral Corundum or Automalite.—Jameson.

Octaedrischer Corund, Mohs.—Automalite, Werner.—Spinelle Zincifere, Haüy.

Specific Character.—Tessular. Cleavage, octahedral, and easily obtained. Hardness = 8. Sp. gr. = 4.1, — 4.3.

Description.—Colour green. Occurs regularly crystallized. External lustre pearly, inclining to semi-metallic, internally shining and resinous. Fracture conchoidal. Opaque or faintly translucent on the edges.

Geognostic and Geographic Situations.—Occurs imbedded in talc, and associated with lead-glance at Fahlun in Sweden.

3. Rhomboidal Corundum.—Jameson.

Rhomboedrischer Corund, Mohs.

Specific Character.—Rhomboidal. Rhomboid = $86^\circ 6'$. Cleavage R— ∞ . More perfect R. Hardness = 9.0. Sp. gr. = 3.8, — 4.3.

Description.—Colours blue, red, grey, white, green, yellow, brown, and black. Occurs regularly cry-

stallized and massive. Lustre ranges from splendid to glimmering, and vitreous, or vitreous sometimes inclining to adamantine. Fracture conchoidal and uneven. Ranges from transparent to feebly translucent on the edges.

The transparent blue varieties are named *sapphire*; the transparent red varieties, *oriental ruby*; the massive, nearly opaque, grey and black varieties, *emery*; the translucent, massive, and crystallized varieties, *common corundum*; and the brown faintly translucent varieties, *adamantine spar*.

Geognostic and Geographic Situations.—The finest sapphires and oriental rubies are found in alluvial soil in Ceylon and Pegu, and other countries; the emery occurs in primitive talc-slate in Saxony; the common corundum and adamantine spar in granite, syenite, and other rocks in India and China.

4. Prismatic Corundum, or Chrysoberyl.—Jameson.

Prismatischer Corund, Mohs.—Krysoberyll, Werner.—Cymophane, Haüy.

Specific Character.—Prismatic. Pyramid = $139^\circ 53'$; $86^\circ 16'$; $107^\circ 29'$. $P + \infty = 128^\circ 35'$. Cleavage = $Pr + \infty$. Less perfect $Pr + \infty$. (Fig. 29, 28.) Hardness = 8.5. Sp. gr. = 3.7, — 3.8.

Description.—Colour green, and often exhibits a milk-white opalescence. Occurs regularly crystallized, and in blunt edged pieces. Lustre splendid and resino-vitreous. Fracture conchoidal. Semi-transparent and transparent.

Geognostic and Geographic Situations.—Occurs imbedded in granite veins in America, and in alluvial soil in Ceylon.

Genus III.—DIAMOND.

Tessular. Hardness = 10. Sp. gr. = 3.4, — 3.6.

1. Octahedral Diamond.—Jameson.

Specific Character.—Tessular. Cleavage octahedral.

Description.—Its colours are more numerous than that of most other minerals, and of the various tints the grey and white are the most frequent; and it exhibits beautiful red, yellow, and blue varieties. Occurs regularly crystallized, and in roundish grains. The lustre splendid and adamantine. Fracture conchoidal. Transparent and semi-transparent.

Geognostic and Geographic Situations.—It has hitherto been found principally loose in alluvial soil, in the warmer regions of the earth, as Brazil, Borneo, and the Peninsula of India.

Genus IV.—TOPAZ.

Prismatic. Cleavage axotomous. Hardness = 8. Sp. gr. = 3.4, — 3.6.

1. Prismatic Topaz.—Jameson.

Prismatischer Topaz, Mohs.—Topaz. Physalit. Piktin, Werner.—Silice Fluatée Alumineuse, Haüy.

Specific Character.—Prismatic. Pyramid = $141^\circ 7'$; $101^\circ 52'$; $90^\circ 55'$. $P + \infty = 124^\circ 19'$. Combination, sometimes with different planes on opposite ends. Cleavage, $P + \infty$. (Fig. 27.)

Description.—Colours yellow, green, blue, red,

Mineralogy. grey, white. Occurs regularly crystallized; also in prismatic and granular concretions, and massive. Lustre ranges from splendid to glistening, and is vitreous and resinous. Fracture conchoidal and uneven. Ranges from transparent to translucent on the edges. Easily and uncommonly easily frangible.

The highly crystallized and transparent varieties are named *precious topaz*; those in prismatic distinct concretions, with a slight degree of translucency on the edges, and which are uncommonly easily frangible, *schorlous topaz*; and those in coarse granular concretions, with a low degree of lustre, and feeble translucency on the edges, *physalite*.

Geognostic and Geographic Situations.—Precious topaz occurs in alluvial soil in the upper parts of Aberdeenshire, and in primitive rocks in Cornwall; *schorlous topaz* is said also to occur in Aberdeenshire; and the *physalite* in granite, at Finbo in Sweden.

Genus V.—EMERALD.

Rhombohedral. Prismatic. Cleavage rhomboidal-axotomous and peritomous, or prismatoidal. Hardness = 7.5, 8.0. Sp. gr. = 2.6, —3.2.

1. *Prismatic Emerald, or Euclase*.—Jameson.

Euclase, *Werner*.—Prismatischer Smaragd, *Mohs*.—Euclase, *Hay*.

Specific Character.—Prismatic. Pyramid unknown. $P + \infty = 133^\circ 26'$. Combination, hemiprismatic. $\frac{P}{2}$. Cleavage, $P + \infty$. Very distinct.

Hardness = 7.5. Sp. gr. = 2.9, —3.2.

Description.—Colours green, white, and blue. Occurs regularly crystallized. Lustre splendid. Fracture conchoidal. Transparent and translucent. Very easily frangible.

Geognostic and Geographic Situations.—This beautiful and rare mineral has been hitherto found only in Peru and Brazil.

2. *Rhombohedral Emerald*.—Jameson.

Rhomboedrischer Smaragd, *Mohs*.—Emeraude, *Hay*.

Specific Character.—Rhombohedral, $R = 104^\circ 28'$. Combination di-rhombohedral. $2(R) = 138^\circ 35'$: 90. Cleavage, $R = \infty$. Less perfect, $P + \infty$. Hardness = 7.5, —8.0. Sp. gr. = 2.6, —2.8.

Description.—Colours green, blue, yellow, and grey. Occurs regularly crystallized, and in thin prismatic concretions. Lateral planes longitudinally streaked or smooth. Lustre ranges from splendid to glistening, and is vitreous. Fracture conchoidal. Ranges from transparent to translucent on the edges. Easily frangible.

The varieties, with emerald-green colours, and, in short, smooth, transparent, and translucent prisms, with rough terminal planes, are named *precious emerald*, while the others, in which the colours are green, blue, yellow, and grey, and crystallized in long longitudinally streaked prisms, are named *beryl*, or *common emerald*.

Geognostic and Geographic Situations.—The precious emerald is found in mica-slate, and clay-slate.

Mineralogy. and the finest varieties are those imported from Peru. The beryl, or common emerald, occurs in Aberdeenshire; but nearly all the varieties, met with in trade, are brought from Russia.

Genus VI.—QUARTZ.

Rhombohedral, prismatic. Cleavage not axotomous. Hardness = 5.5, —7.5. Sp. gr. = 1.9, —2.7.

1. *Prismatic Quartz, or Iolite*.—Jameson.

Prismatischer Quarz, *Mohs*.—Iolith, *Pellom*, *Werner*.—Iolithe, *Hay*.—Dichroite. Steinheilite, *Auct*.

Specific Character.—Prismatic. Pyramid unknown.

Cleavage, $P + \infty = 120^\circ$ (nearly). $Pr + \infty$ (Fig. 30, 29.) Hardness = 7.0, —7.5. Sp. gr. = 2.5, —2.6.

Description.—Colour blue. Of an indigo blue colour, when viewed in the direction of the axis, but viewed perpendicular to the axis, is brownish yellow. Occurs rarely crystallized, generally massive and disseminated. Lustre shining and vitreous. Fracture uneven and conchoidal. Translucent in the direction of the axis, and transparent at right-angles to it.

Geognostic and Geographic Situations.—Occurs in granite, gneiss, and it is said also in volcanic tuffa; Abo in Finland, Arendal in Norway, St Gothard in Switzerland, and Granatillo in Spain, are localities of this mineral.

2. *Rhombohedral Quartz*.—Jameson.

Quartz, *Werner*.—Rhomboedrischer Quarz, *Mohs*.

Specific Character.—Rhombohedral. Rhomboid = $75^\circ 47'$. Combination, hemi-rhombohedral and hemidirhombohedral. $R + n$ and $(P + n')$, with inclined planes, and $P + n''$ with parallel planes. Cleavage, $P = 133^\circ 38'$; $103^\circ 53'$. $P + \infty$. Hardness = 7.0. Sp. gr. = 2.5, —2.7.

Description.—Colours white, grey, rarely black, blue, green, yellow, red, and brown. Occurs regularly crystallized; in granular, fibrous, prismatic, and lamellar concretions; also massive, disseminated, in plates, stalactitic, reniform, botryoidal, globular, specular, vesicular, and cellular. Lustre ranges from splendid to glimmering, and is vitreous. Fracture conchoidal, even, uneven, and splintery. Ranges from transparent to opaque. Brittle, and easily frangible.

The transparent and highly crystallized varieties are named *rock crystal*. The pyramidal, translucent, and transparent varieties, having generally a violet blue colour, and disposed in prismatic, fibrous, and lamellar concretions, are named *amethyst*. The massive, strongly translucent, rose-red, and milk-white varieties, are named *rose quartz*. Those varieties which have generally grey or white colours, the pyramidal form, and occur massive, disseminated, and in the various particular external forms enumerated above, with a low degree of lustre and translucency, are named *common quartz*. The leek-green translucent varieties, with a resino-vitreous lustre, and conchoidal-splintery fracture, are named *prase*. The *cat's eye* is a variety, with a beautiful opalescence, like the light of the eye of the cat. Those opaque varieties, in which the colours are red, brown, and yellow, and the lustre shining externally, and glist-

Mineralogy. ening internally, and vitreo-resinous, and fracture small conchoidal, are named *iron-flint*. Those varieties which exhibit grey, yellow, brown, red, and green, generally muddy colours, and which occur massive and in extraneous external shapes, with a splintery, or conchoidal, and dull, or glimmering fracture, and are opaque or translucent on the edges, are named *horn-stone*. The grey, brown, and black varieties which generally occur massive, and in various particular and extraneous external forms, and exhibit a glimmering lustre, conchoidal fracture, and feeble translucency, are named *flint*. The semi-transparent and translucent varieties, in massive and various particular external forms, with an even and dull fracture surface, are named *common calcedony*. The beautiful apple-green strongly translucent varieties are named *chrysoprase*. The grass-green varieties, with glimmering lustre, conchoidal fracture, and strong translucency, are named *plasma*. The semi-transparent and strongly translucent varieties, with glistening or shining vitreous lustre and conchoidal fracture, and with various tints of red, brown, yellow, green, and white, are named *carnelian*. The beautiful variety, named *heliotrope*, is well characterized, on a general view, by its green colour, and disseminated spots of red and yellow jasper. Those varieties, in which the colours are red, brown, and black, and seldomer yellow or green, which occur massive and disseminated, with a fracture ranging from conchoidal to earthy, and lustre from glistening to dull, and are opaque, are named *jasper*. And, lastly, the white and grey varieties, which are so porous and light, as to swim on the surface of water, are named *spongiform quartz*, or *floatstone*.

Geognostic and Geographic Situations.—Quartz is very universally distributed, and, as far as we know at present, is the most abundant mineral in nature. It occurs in every rock, from granite to the newest secondary formation; and every country, every district in the world, afford examples of this mineral.

3. Uncleavable Quartz.—Jameson.

Untheilbarer Quartz, *Mohs*.

Specific Character.—Reniform....Massive. No cleavage. Hardness = 5.5, —6.5. Sp. gr. = 1.9, —2.2.

Description.—Colours white and grey, also green, yellow, brown, red, and black, and sometimes displays a beautiful play of colour. Occurs massive, and in various particular external forms. Lustre ranges from splendent to glistening, and is vitreous, or vitreo-resinous. Ranges from transparent to opaque.

The grey and white varieties, with glistening and shining pearly lustre, and translucent on the edges, or translucent in the mass, are named *quartz sinter*, or *pearl sinter*. The yellowish and greyish white varieties with the botryoidal and other particular external forms, conchoidal fracture and vitreous lustre, and which are strongly translucent, are named *hyalite*. The milk-white varieties, with the beautiful play of various rich and pure colours, are named *precious opal*. The transparent varieties, with the beautiful carmine-red and apple-green iridescence, are named *fire opal*. Those varieties which are milk-white, and frequently dendritic, with a pearly, shining, or glistening lustre,

conchoidal fracture, and complete opacity, are named *mother-of-pearl opal*, or *cacholong*. The common *opal* differs from the precious, principally in wanting the play of colour. The feebly translucent varieties, with conchoidal fracture, and glistening vitreo-resinous lustre, and white, grey, and brown colours, are named *semi-opal*. Those varieties, in which the colours are red, yellow, and grey, with a shining vitreo-resinous lustre, conchoidal fracture, and opacity, are named *jasper-opal*. Those varieties which occur in various vegetable forms, and are really vegetables impregnated, or petrified with opal, are named *wood-opal*. And, lastly, the brown and yellowish grey tuberoso varieties are named *menilite*.

Geognostic and Geographic Situations.—This species has a comparatively limited geognostic and geographic distribution. The quartz sinter occurs in the vicinity of hot-springs, as in Iceland and other countries; the hyalite in secondary trap-rocks in Scotland, Germany; and the various opals are found principally in secondary trap, and in porphyry rocks in Hungary, Germany, Scotland, and other countries.

4. Fusible Quartz.—Jameson.

Empyrodox Quartz, *Mohs*.

Specific Character.—In grains....Massive. No cleavage. Hardness = 6.0, —7.0. Sp. gr. = 2.2, —2.4.

Description.—Colours black, green, and grey; also brown, blue, red, yellow, and white. Occurs in globular, lamellar, and prismatic concretions; massive, vesicular, and porous. Lustre ranges from splendent to glimmering, and is vitreous, resinous and pearly. Ranges from transparent to opaque.

The varieties, with splendent and vitreous lustre, conchoidal fracture, and ranging from transparent to translucent on the edges, are named *obsidian*; those again in which the lustre is shining and resinous, and translucent on the edges, are named *pitchstone*; the beautiful varieties in globular and concentric lamellar, shining, pearly, translucent concretions, are named *pearlstone*; and lastly, the white and grey varieties, which are vesicular and fibrous, with a vitreous or pearly lustre, and often so light as to swim on water, are named *pumice*.

Geognostic and Geographic Situations.—All the minerals of this series are, by some, said to be of volcanic origin, by others to have a double origin, in some cases being volcanic, in others of Neptunian formation. The pitchstone abounds in Scotland, in the Island of Arran, also in the Isle of Egg, in Ruin, Skye, and other quarters; pearlstone occurs in great beauty in Hungary and Iceland, and both pumice and obsidian are productions of Iceland, the Lipari Islands, and of other districts, said to be of volcanic origin.

Genus VII.—AXINITE.

Perfect vitreous lustre. Hardness = 6.5, —7.0. Specific gravity = 3.0, —3.3.

1. Prismatic Axinite.—Jameson.

Prismatischer Axinit, *Mohs*.—Thunerstein, *Werner*.—Axinite, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown.

Mineralogy. Combination, tetarto-prismatic. Cleavage, two faces, the one more distinct than the other. Incidence = $101^{\circ} 30'$.

Description.—Colours brown, blue, and sometimes grey and black. Occurs regularly crystallized; in curved lamellar concretions, and massive. Lustre externally splendid, internally glistening, or shining, and vitreous. Ranges from transparent to feebly translucent. Brittle, and very easily frangible.

Geognostic and Geographic Situations.—Occurs in beds and veins in gneiss, mica-slate, clay-slate, and hornblende-slate. It occurs in small quantities in Cornwall, but no where else in Great Britain.

Genus VIII.—CHRYSLITE.

Perfect vitreous lustre. Hardness = 6.5, —7.0. Sp. gr. = 3.3, —3.5.

1. Prismatic Chrysolite.—Jameson.

Prismatischer Krisolith, *Mohs.*—Peridot, *Haüy.*

Specific Character.—Prismatic. Pyramid = $107^{\circ} 46'$; $101^{\circ} 31'$; $119^{\circ} 41'$. $P + \infty = 94^{\circ} 3'$. Cleavage, $Pr + \infty$. Less distinct $Pr + \infty$. (Fig. 29, 28.)

Description.—Colour green. Occurs regularly crystallized. Lustre splendid and vitreous. Fracture conchoidal. Transparent.

The varieties in granular distinct concretions, and which have a lower degree of transparency and lustre than the more highly crystallized kinds, are those generally described under the name *olivine*.

Geognostic and Geographic Situations.—The mineral occurs principally in secondary trap-rocks, and in alluvial strata. The olivine variety is not unfrequent in some of the middle and western districts of Scotland. The chrysolites of commerce are brought from the Brazils and Upper Egypt.

Genus IX.—BORACITE.

Tessular. Hardness = 7. Sp. gr. = 2.8, —3.0.

1. Octahedral Boracite.—Jameson.

Octaedrischer Borazit, *Mohs.*—Borazit, *Werner.*—Magnesie Boratée, *Haüy.*

Specific Character.—Tessular. Combination, semi-tessular of inclined planes. Cleavage, imperfect.

Description.—Colours white and grey. Occurs regularly crystallized. Internally shining and adamantine. Fracture conchoidal. Translucent and transparent.

Geognostic and Geographic Situations.—Occurs imbedded in secondary gypsum, in Hanover and Holstein.

Genus X.—TOURMALINE.

Rhombohedral. Hardness = 7.0, —7.5. Sp. gr. = 3.0, —3.2.

1. Rhombohedral Tourmaline.—Jameson.

Rhomboedrischer Turmaline, *Mohs.*—Tourmaline, *Haüy.*

Specific Character.—Rhombohedral. Rhomboid = $133^{\circ} 26'$. Combination, with different planes on opposite extremities. Cleavage, R. $P + \infty$.

Description.—Colours black, brown, green, blue,

red, and white. Occurs regularly crystallized; in prismatic and granular distinct concretions, massive and disseminated. Lustre ranges from splendid to glistening, and is vitreous. Fracture conchoidal and uneven. Ranges from transparent to opaque. Brittle and easily frangible.

The black coloured opaque varieties, with uneven fracture, are named *schorl*; all the others are ranged under the title *tourmaline*.

Geognostic and Geographic Situations.—It occurs imbedded in granite, gneiss, mica-slate, talc-slate, chlorite slate, dolomite, topaz-rock, and quartz-rock; also in felspar, mica, talc, &c. and in alluvial strata. The schorl varieties occur in various primitive rocks in the Alpine districts of Scotland, and the purer varieties, or tourmaline, properly so called, are met with in Siberia, Spain, and many other countries.

Genus XI.—GARNET.

Tessular, pyramidal, prismatic. Lustre not pure vitreous. Hardness = 6.0, —7.5. Sp. gr. = 3.0, —4.3. If colour red, the sp. gr. = 3.7, and more. If black, sp. gr. = 3.9, and less. If hardness, 7.5, the colour is red or brown.

1. Pyramidal Garnet, or Vesuvian.—Jameson.

Pyramidaler Granat, *Mohs.*—Vesuvian, and Egeran, *Werner.*—Idocrase, *Haüy.*

Specific Character.—Pyramidal. Pyramid = $129^{\circ} 29'$; $74^{\circ} 14'$. Cleavage, $P - \infty$. $P + \infty$. [$P + \infty$]. Hardness = 6.5. Sp. gr. = 3.3, —3.4.

Description.—Colours green and brown, and rarely blue. Occurs regularly crystallized; in granular distinct concretions, massive, and disseminated. Externally splendid, and internally feebly shining and vitreo-resinous. Fracture uneven, inclining to small conchoidal. Ranges from transparent to translucent in the edges.

Geognostic and Geographic Situations.—Occurs in primitive rocks in Ireland, also in Scotland; and on the continent of Europe the most beautiful varieties are there found in the unaltered ejected masses in Somma, near Naples, where they are associated with granular limestone, garnet, hornblende, mica, chlorite, augite, meionite, nepheline, magnetic iron-ore, &c.

2. Tetrahedral Garnet, or Helvine.—Jameson.

Helvin, *Werner.*—Tetraedrischer Granat, *Mohs.*

Specific Character.—Tessular. Combination, semi-tessular of inclined planes. Cleavage, octahedral, but imperfect. Hardness = 6.0, —6.5. Sp. gr. = 3.1, —3.3.

Description.—Colours yellow, green, and brown. Occurs regularly crystallized, and in granular distinct concretions. Lustre ranges from splendid to glistening and vitreo-resinous. Fracture uneven. Translucent.

Geognostic and Geographic Situations.—Occurs in a bed in gneiss, associated with fluor-spar, slate-spar, chlorite, quartz, blende, and copper-pyrites, near Schwarzenberg, in Saxony.

3. Dodecahedral Garnet.—Jameson.

Specific Character.—Tessular. Cleavage dodeca-

Mineralogy. bedral imperfect. Hardness = 6.5,—7.5. Sp. gr. = 3.5,—4.3.

Description.—Colours red, brown, green, black, grey, and yellow. Occurs regularly crystallized; in angular granular concretions, and massive. Lustre ranges from splendid to glimmering, and is vitreous inclining to resinous, resino-vitreous, and resino-adamantine. Fracture conchoidal, splintery, uneven. Ranges from transparent to opaque.

The asparagus-green varieties in leucite formed crystals are named *grossularæ*; the greyish-black dodecahedral opaque varieties, which externally have a metallic-like aspect, *pyreneite*; the velvet-black, dodecahedral, opaque varieties, *melanite*; the green, brown, and grey massive varieties, with glimmering lustre, and feeble translucency on the edges, *allochroite*; the brown and red varieties in granular concretions, with resino-adamantine lustre, *colophonite*; the red highly crystallized transparent varieties, *precious garnet*; the yellow nearly transparent varieties *tupazolite* or *yellow garnet*; the brown and green varieties, in crystals often rounded on the edges, in granular concretions, and translucent, or translucent on the edges, *common garnet*; and lastly, the deep blood-red variety in roundish and angular grains, and completely transparent, *pyrope*.

Geognostic and Geographic Situations.—This mineral occurs principally in primitive rocks, either disseminated through them, or forming any ingredient in the composition of subordinate beds; it is comparatively rare in transition rocks, and is still less frequently met with in secondary formations. In Scotland the precious garnet is common in several Highland districts in Perthshire, Aberdeenshire, &c.; and the pyrope variety occurs in secondary trap-rocks in Fifeshire.

4. Prismatic Garnet, or Cinnamon-Stone.—Jameson.

Prismatischer Garnet, *Mohs.*—Kaneelstein, *Werner.*—Essonite, *Haüy.*

Specific Character.—Prismatic. (Fig. 30.) Pyramid unknown. Cleavage, $P+\infty=102^{\circ}40'$, indistinct. Hardness = 7.0,—7.5. Sp. gr. = 3.5,—3.7.

Description.—Colour intermediate between hyacinth-red and orange-yellow. Occurs in granular distinct concretions, and massive. Lustre shining and resino-vitreous. Fracture conchoidal. Transparent and translucent.

Geognostic and Geographic Situations.—Occurs in gneiss in Kincardineshire; the finer varieties are imported from Ceylon, where they are found in the beds rivers, and also associated with gneiss.

5. Prismatoidal Garnet, or Grenatite.—Jameson.

Prismatoidischer Granat, *Mohs.*—Granatit, *Werner.*—Staurotide, *Haüy.*

Specific Character.—Prismatic. Pyramid = $131^{\circ}54'$; $80^{\circ}48'$; $124^{\circ}48'$. $P+\infty=129^{\circ}30'$. Cleavage, $P+\infty$, perfect. (Fig. 29.) Hardness = 7.0,—7.5. Sp. gr. = 3.3,—3.9.

Description.—Colour reddish brown. Occurs regularly crystallized. Internally the cleavage is shining and splendid; fracture glistening and glimmering,

and resino-vitreous, Fracture uneven. Ranges from semi-transparent to opaque.

Geognostic and Geographic Situations.—Occurs in primitive rocks in the Shetland Islands and in Aberdeenshire, and other parts of Scotland.

* *Aplome.*—Colour dark brown. Tessular. Cleavage, hexahedral. Hardness = 7. Sp. gr. = 3.446.

** *Eudialite.*—Colour brownish red. Rhomboidal, $R=62^{\circ}$. Cleavage, $R-\infty$. Less distinct, $P+\infty$. Hardness = 5.0,—5.5. Sp. gr. = 2.8,—3.0. Its native country is West Greenland.

Genus XII.—ZIRCON.

Pyramidal. Hardness = 7.5. Sp. gr. = 4.5,—4.7.

1. Pyramidal Zircon.—Jameson.

Pyramidaler Zircon, *Mohs.*

Specific Character.—Pyramidal. Pyramid = $123^{\circ}19'$; $84^{\circ}20'$. Cleavage, $P, P+\infty$.

Description.—Colours grey and hyacinth red; also white, green, brown, and rarely yellow, blue, and red. Occurs regularly crystallized. Lustre splendid, shining, and adamantine-resinous and resino-vitreous. Fracture conchoidal. Ranges from transparent to opaque.

Those varieties in which the cleavage is very distinct, and which have frequently a hyacinth red colour, are named *hyacinth*, the other varieties *common zircon*.

Geognostic and Geographic Situations.—Occurs in syenite, granite, gneiss, primitive trap, in secondary trap, and unaltered ejected masses of Somma. The syenite rocks of Galloway, the gneiss rocks of Inverness-shire and of the Shetland Islands, afford examples of this mineral.

Genus XIII.—GADOLINITE.

Prismatic. Colour black. Hardness = 6.5,—7.0. Sp. gr. = 4.0,—4.3.

1. Prismatic Gadolinite.—Jameson.

Prismatischer Gadolinit, *Mohs.*

Specific Character.—Prismatic. Pyramid unknown. $P+\infty=110^{\circ}$ (nearly). Combination, hemiprismatic.

Description.—Colour black, and rarely hyacinth red. Occurs in granular and prismatic concretions, and massive. Internally shining, and lustre, resino-vitreous. Fracture conchoidal, seldom uneven. Opaque.

Geognostic and Geographic Situations.—Occurs in beds of felspar, in mica-slate at Ytterby, and in granite at Finbo, in Sweden.

Order VIII.—ORE.

Hardness = 2.5, 7. Sp. gr. = 3.4,—7.4. If the lustre is metallic, the colour is black. If the lustre is not metallic, it is adamantine or imperfect, or semi-metallic lustre. If the streak is yellow or red, the hardness = 3.5, and more, and the sp. gr. = 4.8, and more. If the streak is brown or black, the hardness = 5.0, and more, or the cleavage montomous. If the hardness = 4.5, and less, the streak is yellow, red, or black. If hardness = 6.5, and more, the streak is white or grey, and the sp. gr. = 6.5, and more.

Genus I.—TITANIUM-ORE.

Pyramidal, prismatic. Hardness = 5.0, —6.5. Sp. gr. = 3.4, —4.4. If sp. gr. less than 4.2, the streak is white or grey.

1. *Prismatic Titanium-Ore, or Sphene*.—Jameson.

Prismatisches Titan-erz, *Mohs*.—Titane Siliceo-calcaire, *Hauy*.

Specific Character.—Prismatic. Pyramid = $111^\circ 12'$; $88^\circ 47'$; $131^\circ 16'$. $P + \infty = 103^\circ 20'$. Combination, hemiprismatic. $\frac{P}{2} = 111^\circ 12'$. Cleavage, $\frac{P}{2}$. (Fig. 37.) Streak white or grey. Hardness =

5.0, —5.5. Sp. gr. = 3.4, —3.6.

Description.—Colours brown, yellow, green, grey, and white. Occurs regularly crystallized; in granular and lamellar distinct concretions, and massive. Lustre ranges from splendid to glistening, and is adamantine. Fracture conchoidal. Ranges from transparent to opaque.

One set of varieties, in which brown is the predominating colour, is named *common sphene*, or *brown titanium-ore*; and another, in which the principal colours are yellow, and the cleavage distinct, is named *yellow titanium-ore*, or *foliated sphene*.

Geognostic and Geographic Situations.—This mineral occurs imbedded in syenite in Inverness-shire, Perthshire, Galloway, and many other quarters of Scotland; it also occurs in syenite rocks in England.

2. *Peritomous Titanium-Ore, or Rutile*.—Jameson.

Peritomes Titan-erz, *Mohs*.—Titan-oxyd \acute{e} , *Hauy*.—Rutil, *Werner*.

Specific Character.—Pyramidal. Pyramid = $117^\circ 2'$; $95^\circ 13'$. Cleavage, $P + \infty$. [$P + \infty$]. Streak brown. Hardness = 6.0, —6.5. Sp. gr. = 4.2, —4.4.

Description.—Colours brown, red, yellow, and sometimes nearly velvet black. Occurs regularly crystallized, massive, disseminated, in angular grains and in flakes. Lustre metallo-adamantine and adamantine, and ranges from splendid to glistening. Fracture conchoidal. Ranges from transparent to opaque.

The dark-brown and black opaque varieties are named *nigrine*; the others *rutile*.

Geognostic and Geographic Situations.—The rutile varieties occur in the granite of Cairngorm; at Killin, and in Ben-Gloe, in quartz rock. The nigrine varieties are met with at Ely, in Fifeshire, and also in Bohemia and Transylvania.

3. *Pyramidal Titanium, or Octahedrite*.—Jameson.

Pyramidales Titan-erz, *Mohs*.—Octaedrit, *Werner*.—Titane, Anatase, *Hauy*.

Specific Character.—Pyramidal. Pyramid = $97^\circ 38'$; $137^\circ 10'$. Cleavage, $P - \infty$. P . Streak white. Hardness = 5.5, —6.0. Sp. gr. = 3.8, —3.9.

Description.—Colours blue and brown. Occurs regularly crystallized. Lustre splendid and adamantine, inclining to semi-metallic. Translucent and transparent.

Geognostic and Geographic Situations.—Occurs in veins in primitive rocks in Saxony and in Norway.

Genus II.—ZINC-ORE.

Prismatic. Hardness = 4.0, 4.5. Sp. gr. = 6.2, —6.3.

1. *Prismatic Zinc-Ore*.—Jameson.

Specific Character.—Prismatic. Pyramid unknown.

Cleavage $P + \infty = 125^\circ$ (nearly). Traces of $P_r + \infty$. (Fig. 30, 29.) Streak orange-yellow.

Description.—Colour red. Occurs massive, and disseminated. Internally shining. Fracture conchoidal. Translucent on the edges, or opaque.

Geognostic and Geographic Situations.—Occurs imbedded in primitive limestone and magnetic iron-ore in Sussex county, and New Jersey, in North America.

Genus III.—RED COPPER-ORE.

Tessular. Hardness = 3.5, —4.0. Sp. gr. = 5.6, —6.0.

1. *Octahedral Red Copper-Ore*.—Jameson.

Octaedrisches Kupfererz, *Mohs*.—Roth Kupfererz, *Werner*.—Chivre oxydul \acute{e} , *Hauy*.

Specific Character.—Tessular. Cleavage octahedral. Streak red.

Description.—Colours red. Occurs regularly crystallized, and in granular distinct concretions; massive, disseminated, and in flakes. Lustre ranges from shining to glimmering, and is adamantine, inclining to semi-metallic. Fracture uneven. Ranges from translucent to opaque.

The varieties with cleavage are named *foliated red copper-ore*; those which are massive, glistening, and opaque, *compact red copper-ore*; and the varieties in capillary crystals, *capillary red copper-ore*.

Geognostic and Geographic Situations.—Occurs in veins in gneiss, mica-slate, clay-slate, and grey-wacke; and in veins and beds in secondary rocks. The copper mines of Cornwall afford fine examples of this beautiful ore.

Genus IV.—TIN-ORE.

Zinnerz, *Mohs*.

Pyramidal. Streak not black. Hardness = 6.0, —7.0. Sp. gr. = 6.3, —7.0.

1. *Pyramidal Tin-Ore*.—Jameson.

Pyramidales Zinnerz, *Mohs*.

Specific Character.—Pyramidal. Pyramid = $133^\circ 25'$; $67^\circ 59'$. Cleavage $P + \infty$. [$P + \infty$]. Streak white, grey, and brown.

Description.—Colours brown, black, green, white, yellow, and red. Occurs regularly crystallized; also reniform, botryoidal, and globular, and in delicate fibrous concretions. Externally splendid; internally ranges from splendid to glimmering, and is adamantine, inclining to resinous. Fracture uneven. Ranges from semi-transparent to opaque.

The varieties in fibrous concretions are named *wood-tin*, the others *common tinstone*.

Geognostic and Geographic Situations.—Occurs in granite, gneiss, mica-slate, clay-slate, porphyry, and in alluvial depositions. The mines of Cornwall afford all its varieties.

Genus V.—WOLFRAM-ORE.

Scheel-erz, *Mohs.*

Prismatic. Hardness = 5.0, — 5.5. Sp. gr. = 7.1, — 7.4.

1. *Prismatic Wolfram*.—Jameson.

Prismatisches Scheel-erz, *Mohs.*—Wolfram, *Werner*.—Scheelin ferrugine, *Haüy.*

Specific Character.—Prismatic. Pyramid = $115^{\circ} 23'$; $98^{\circ} 12'$; $115^{\circ} 23'$. $P + \infty = 98^{\circ} 12'$. Combination hemi-prismatic, $\frac{P}{2} = 115^{\circ} 23'$. Cleavage, $P + \infty$, perfect. (Fig. 29.) Streak dark reddish-brown.

Description.—Colour brownish-black. Occurs regularly crystallized, and massive. Lustre ranges from splendid to glistening, and is adamantine, inclining to resinous. Fracture uneven. Opaque.

Geognostic and Geographic Situations.—Occurs in primitive rocks in the Island of Ronø, one of the Hebrides, and in Cornwall.

Genus VI.—TANTALUM-ORE.

Tantal-erz, *Mohs.*

Prismatic. Streak brownish-black. Hardness = 6.0. Sp. gr. = 6.0, — 6.3.

1. *Prismatic Tantalum-Ore*.—Jameson.

Prismatisches Tantal-erz, *Mohs.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage unknown.

Description.—Colour black. Occurs regularly crystallized; massive and disseminated. Lustre shining and glistening, and semi-metallic-adamantine. Fracture uneven, or conchoidal. Opaque.

Geognostic and Geographic Situations.—Occurs in granite in Finland; in granite, along with beryl, iolite, uran-mica, and iron pyrites, at Bodenmais, in Bavaria.

Genus VII.—URANIUM-ORE.

Uran-erz, *Mohs.*

Form unknown. Streak black. Hardness = 5.5. Sp. gr. 6.4, — 6.6.

1. *Uncleavable Uranium-Ore*.—Jameson.

Untheilbares Uran-erz, *Mohs.*—Uran-pecherz, *Werner*.—Uran oxydulé, *Haüy.*

Specific Character.—Uncleavable, reniform, and massive. No cleavage.

Description.—Colour black. Occurs in granular, lamellar, and prismatic concretions; also massive, and reniform. Lustre shining, and adamantine, inclining to semi-metallic. Fracture conchoidal, passing into uneven. Opaque.

Geognostic and Geographic Situations.—Occurs in veins in primitive rocks, along with native silver, red silver, iron and copper pyrites, galena, blende, and brown-spar. The only British locality is Cornwall.

Genus VIII.—CERIUM-ORE.

Cerer-erz, *Mohs.*

Form unknown. Streak white. Hardness = 5.5. Sp. gr. = 4.6, — 5.0.

1. *Uncleavable Cerium-Ore*.—Jameson.

Untheilbares Cerer-erz, *Mohs.*—Cerer-erz, *Werner*.—Cerium oxyde silicifère, *Haüy.*

Specific Character.—Massive. No cleavage.

Description.—Colours red and brown. Occurs massive and disseminated. Internally glimmering, and adamantine. Fracture splintery. Opaque.

Geognostic and Geographic Situations.—Occurs in a bed of copper pyrites in gneiss, near Ridderhyttan, in Westmannland, in Sweden.

* *Allanite, or Prismatic Cerium Ore.*

Colour brownish-black. Prismatic. $P + \infty = 117^{\circ}$ (nearly.) Streak greenish-grey. Sp. gr. = 3.5, — 4.0. Found in West Greenland.

** *Cerin.*

Colour brownish-black. Prismatic. Cleavage prismatic. Streak yellowish grey...brown. Hardness = 5.5, — 6.0. Sp. gr. = 4.1, — 4.3. Found in Sweden.

Genus IX.—CHROME-ORE.

Chrom-erz, *Mohs.*

Prismatic. Streak brown. Hardness = 5.5. Sp. gr. = 4.4, — 4.5.

1. *Prismatic Chrome-Ore, or Chromat of Iron*.—Jameson.

Prismatisches Chrom-erz, *Mohs.*—Chrom-eisenstein, *Werner*.—Fer chromaté, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage prismatic.

Description.—Colour intermediate between steel-grey and iron-black, and sometimes passes into brownish-black. Occurs regularly crystallized; also in granular distinct concretions; massive and disseminated. Internally shining and glistening, and imperfect metallic. Fracture uneven. Opaque.

Geognostic and Geographic Situations.—Occurs in imbedded masses, and in veins in serpentine, porphyry, and secondary trap. In Scotland it occurs principally in serpentine rocks, and more abundantly in the Shetland Islands than in any other quarter.

Genus X.—IRON-ORE.

Eisen-erz, *Mohs.*

Tessular, rhomboidal, prismatic. Hardness = 5.0, — 6.5. Sp. gr. = 3.8, — 5.2. If the streak is brown, the sp. gr. is below 4.2, or above 4.8. If the streak is black, the sp. gr. is above 4.8.

1. *Octahedral Iron-Ore*.—Jameson.

Octaedrisches eisenerz, *Mohs.*—Fer oxydulé, *Haüy*.—Magnet-eisenstein, *Werner*.

Specific Character.—Tessular. Cleavage octahedral. Streak black. Hardness = 5.5, — 6.5. Sp. gr. 4.8, — 5.2.

Description.—Colour iron-black. Occurs regularly crystallized; in granular distinct concretions, and in loose grains; massive and disseminated. Lustre ranges from splendid to glistening, and is metallic. Fracture uneven, or conchoidal. Opaque.

The variety in grains is named *iron-sand*. The other varieties, *common magnetic iron ore*.

Geognostic and Geographic Situations.—Occurs in

Mineralogy. beds, often of vast thickness and great extent, in rocks of the older formations, as gneiss, mica-slate, hornblende-slate, clay-slate, and primitive greenstone, variously disposed in granite, syenite, serpentine, and chlorite-slate; less frequently in transition rocks, in veins, beds, and imbedded masses, as in transition porphyry; and still less frequently in secondary trap-rocks. The serpentine, chlorite, and gneiss rocks of the Shetland Islands afford examples of this ore; the same is the case on the Mainland of Scotland, both in primitive and secondary rocks.

2. Rhomboidal Iron-Ore.—Jameson.

Rhomboedrisches Eisen-erz, *Mohs*.—Fer oligiste, *Hauy*.

Specific Character.—Rhomboidal. Rhomboid = $85^{\circ} 58'$. Cleavage R. Sometimes R— ∞ . Streak red, ... reddish-brown. Hardness = 5.5, —6.5. Sp. gr. = 4.8, —5.2.

Description.—Colours dark steel-grey bordering on iron-black, iron-black and brownish-red. Occurs regularly crystallized; in granular, lamellar, and fibrous distinct concretions; massive, disseminated, reniform, botryoidal, stalactitic, and globular. Lustre ranges from splendid to dull, and is metallic and semi-metallic. Fracture conchoidal or earthy. Ranges from translucent to opaque.

The dark steel-grey and iron-black varieties, which are generally more or less regularly crystallized, are named *specular iron-ore*, or *iron-glance*; the red varieties are named *red iron-ore*.

Geognostic and Geographic Situations.—The specular iron-ore occurs in gneiss, granite, mica-slate, transition clay-slate, greywacke, and less frequently in secondary rocks. The Island of Elba affords the richest and most beautiful varieties of specular iron-ore, and specimens of considerable beauty are met with in Fifehead in Shetland, and near Dunkeld in Perthshire. The red iron-ore occurs also in primitive rocks, but less frequently than in those of the transition class, as greywacke and transition clay-slate; and considerable depositions of it are met with in secondary sandstone districts. Ulverstone in Lancashire and other parts of England afford beds and veins of this ore.

3. Prismatic Iron-Ore.—Jameson.

Prismatisches Eisen-erz, *Mohs*.—Braun Eisenstein, *Werner*.—Fer oxydé, *Hauy*.—Fer Hydraté, *Dau-buisson*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage prismatic. Streak yellowish-brown. Hardness = 5.0, —5.5. Sp. gr. = 3.8, —4.2.

Description.—Colours brown and yellow. Occurs regularly crystallized; in granular, fibrous, and lamellar distinct concretions; massive, stalactitic, coralloidal, reniform, botryoidal, tuberoso, cylindrical, and fruticose. Lustre glimmering and semi-metallic, inclining more or less to adamantine. Fracture uneven, even, conchoidal, or earthy. Translucent on the edges, or opaque.

Geognostic and Geographic Situations.—Occurs in veins, beds, lenticular masses, and mountain masses, in primitive, transition, and secondary rocks in Great Britain, Germany, and other countries.

* Bog Iron-Ore.—Jameson.

Mineralogy.

Raseneisenstein, *Werner*.

Description.—Colour brown. Occurs massive, vesicular, corroded, amorphous, and tuberoso. Some varieties are friable. Lustre ranges from glistening to dull, and is semi-metallic-resinous. Fracture earthy or conchoidal. Opaque. Yields a yellowish-grey streak. Brittle, and easily frangible. Sp. gr. = 2.944.

Geognostic and Geographic Situations.—It occurs in alluvial soil and in peat-mosses in various places of Scotland, and in the Orkney, Shetland, and Western Islands.

** Lievrite. Ienite. Ilvaite.

Fer Siliceo-calcaire, *Hauy*.

Specific Character.—Prismatic. Pyramid = 1398 57'; 117° 38'; 773 16'. Cleavage Pr = 113° 2'. P + ∞ = 112° 37'. Pr + ∞ . None distinct. Colour black. Streak black, inclining sometimes to green or brown. Hardness = 5.5, —6.0. Sp. gr. = 3.825, —4.061.

Description.—Colour black, blackish green. Occurs regularly crystallized; also in distinct concretions, which are scopiform radiated, or straight radiated. Lustre glistening and semi-metallic. Fracture uneven. Opaque.

Geognostic and Geographic Situations.—Occurs associated with epidote, garnet, magnetic iron ore, and arsenic pyrites, in limestone, in the Island of Elba; and has been found in Norway and West Greenland.

Genus XI.—MANGANESE-ORE.

Mangan-erz, *Mohs*.

Prismatic. Hardness = 2.5, —6.0. Sp. gr. = 4.3, —4.8.

1. Prismatic Manganese-Ore, or Black Manganese-Ore.—Jameson.

Prismatisches Mangan-erz, *Mohs*.—Schwarzer Braunstein and Schwarz-eisenstein, *Werner*.—Manganese oxydé, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage unknown, imperfect. Streak black, inclining to brown. Hardness = 5.0, —6.0.

Description.—Colours black and steel-grey. Occurs regularly crystallized; also in fibrous and lamellar distinct concretions; massive, tuberoso, fruticose, reniform, and botryoidal. Lustre glimmering, glistening, and imperfect metallic. Fracture conchoidal and uneven. Opaque.

Geognostic and Geographic Situations.—Occurs in veins in primitive, transition, and secondary rocks in Hanover, Saxony, &c.

* Scaly Brown Manganese-Ore.—Jameson.

Brauner Eisenrahm, *Werner*.

Description.—Colour between steel-grey and clove-brown. Occurs in crusts, massive, spumous, fruticose, and irregular dendritic. Friable, or friable passing into soft. Composed of scaly particles, which are glistening and metallic. Soils. Feels greasy. Occurs in the mines of Sandlodge, in Shetland.

Mineralogy. 2. *Prismatoidal Manganese-Ore, or Grey Manganese-Ore.*—Jameson.

Prismatoidisches mangan-erz, Mohs.—Graubraunsteinerz, Werner.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P \perp \infty = 100^\circ$ (nearly). More distinct, $Pr \perp \infty$. (Fig. 30, 29.) Streak black. Hardness $= 2.5, - 3.0$.

Description.—Colour dark steel-grey, inclining to iron-black. Occurs regularly crystallized; in granular, fibrous, and radiated distinct concretions. Lustre shining, glimmering, and metallic. Fracture conchoidal and earthy.

Geognostic and Geographic Situations.—Occurs in veins and imbedded masses in primitive, transition, and secondary rocks. In Aberdeenshire, it occurs in primitive rocks; in Devonshire, in the vicinity of those of the transition class; and in Cornwall, it is associated with clay-slate.

* *Earthy Grey and Brown Manganese-Ore, or Wad.*—Jameson.

Colours grey and brown. Occurs massive, botryoidal, and sometimes pulverulent. Internally dull, but the grey varieties are glimmering. Yields to the nail. It occurs along with the grey manganese-ore in Devonshire and Cornwall.

** *Phosphat of Manganese.*

Pitchy Iron-ore, Werner.—Manganese Phosphaté, Haüy.

Colour between pitch-black and clove-brown. Occurs massive, and crystallized in oblique prisms. Cleavage, three perpendicular faces, of which one is less perfect than the others. Lustre glistening and resinous. Fracture conchoidal, inclining to even and uneven. Translucent on the edges. Streak yellowish-grey, and brown. Hardness $= 5.0, - 5.5$. Sp. gr. $= 3.430$, Vauquelin. 3.775, Ullman. Occurs in disseminated masses in granite near Limoges, in France.

Order IX.—NATIVE METAL.

Lustre metallic. Not black. Hardness $= 0...5$. Sp. gr. $= 5.7, - 20$. If grey, it is malleable, and the sp. gr. $= 7.4$, and more. If the hardness $= 4.0$, it is malleable.

Genus I.—ARSENIC.

Form unknown. Tin-white, inclining to lead-grey. Hardness $= 3.5$. Sp. gr. $= 5.7, - 5.8$.

1. *Native Arsenic.*—Jameson.

Gediegen Arsenik, Werner and Mohs.—Arsenic natif, Haüy.

Specific Character.—Regular form unknown. Cleavage unknown.

Description.—Colour tin-white, which soon tarnishes black on exposure. Occurs massive, in plates, reniform, botryoidal, reticulated, and with impressions. Lustre glistening, glimmering, and metallic. Fracture uneven. Emits, when struck, a ringing sound, and an arsenical odour.

Geognostic and Geographic Situations.—It occurs in metalliferous veins, particularly where they cross

each other, in gneiss, mica-slate, clay-slate, and porphyry; seldomer in transition and secondary rocks; rarely in beds, and never in large quantity. The mines of Germany, Norway, Franco, and Russia, afford examples of this mineral.

Genus II.—TELLURIUM.

Form unknown. Tin-white. Hardness $= 2.0, - 2.5$. Sp. gr. $= 6.1, - 6.2$.

1. *Native Tellurium.*—Jameson.

Gediegenes Tellur, Mohs.—Gediegen Sylvan, Werner.—Tellur natif, Haüy.

Specific Character.—Regular form unknown. Cleavage unknown.

Description.—Colour tin-white. Occurs in granular distinct concretions, massive, and disseminated. Lustre shining and metallic. Rather brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in greywacke, in Transylvania, and also in Tellemark, in Norway.

Genus III.—ANTIMONY.

Tessular, prismatic. Not ductile. White. Hardness $= 3.0, - 3.5$. Sp. gr. $= 6.5, - 10.0$.

1. *Dodecahedral Antimony, or Native Antimony.*—Jameson.

Dodecaedrisches Antimon, Mohs.—Gediegen Spiesglas, Werner.—Antimoine natif, Haüy.

Specific Character.—Tessular. Cleavage octahedral. Dodecahedral.

Description.—Colour tin-white. Occurs regularly crystallized; in granular and lamellar concretions; massive, disseminated, and reniform. Lustre splendid and metallic.

Geognostic and Geographic Situations.—Occurs in metalliferous veins in primitive rocks in Sweden, and in the mountains of Hanover, Dauphiny, Hungary, and Brazil.

2. *Prismatic Antimony, or Antimonial Silver.*—Jameson.

Prismatisches Antimon, Mohs.—Spiesglas Silber, Werner.—Argent Antimonial, Haüy.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P \perp \infty$. Pr. Less distinct, $P \perp \infty$. (Fig. 27, 34, 30.) Hardness $= 3.5$. Sp. gr. $= 8.9, - 10.0$.

Description.—Colour between silver and tin-white. Occurs regularly crystallized, and massive. Lustre splendid and metallic. Sectile.

Geognostic and Geographic Situations.—Occurs in veins in primitive and transition rocks in Furstenberg, Salzburg, Hartz, and Spain.

Genus IV.—BISMUTH.

Tessular. Silver-white, inclining to red. Hardness $= 2.0, - 2.5$. Sp. gr. $= 8.5, - 9.0$.

1. *Octahedral Bismuth.*—Jameson.

Octaedrisches Wismuth, Mohs.—Gediegen Wismuth, Werner.—Bismuth natif, Haüy.

Specific Character.—Tessular. Cleavage, octahedral.

Mineralogy. *Description.*—Colour silver-white. Occurs regularly crystallized; massive, disseminated, dentiform, and in leaves with a plumose streaked surface. Lustre splendid and metallic. Malleable.

Geognostic and Geographic Situations.—Occurs in veins in primitive rocks, as gneiss, granite, mica-slate, and clay-slate, in Cornwall, Germany, France, Norway, &c.

Genus V.—MERCURY.

Tessular, liquid. Not malleable. White. Hardness = 0.0, —3.0. Sp. gr. = 10.5, —15.0.

1. Liquid Native Mercury.—Jameson.

Flüssiges Mercur, *Mohs.*—Gediegen Quecksilber, *Werner.*—Mercur Natif, *Hauy.*

Specific Character.—Liquid. Tin-white. Hardness = 0. Sp. gr. = 12.0, —15.0.

Description.—Colour tin-white. Liquid. Splendid and metallic. Opaque.

Geognostic and Geographic Situations.—Rarely in primitive and transition rocks. More frequently in rocks of the coal formation. Deux-Ponts, Idria, and other European mining districts, afford examples of this metal.

2. Dodecahedral Mercury, or Native Amalgam.—Jameson.

Dodecaedrisches Mercur, *Mohs.*—Natürlich Amalgam, *Werner.*—Mercur Argentat, *Hauy.*

Specific Character.—Tessular. No cleavage. Silver-white. Hardness = 1.0, —3.0. Sp. gr. = 10.5, —12.5.

Description.—Colour silver-white. Occurs regularly crystallized. Lustre shining and metallic. Fracture uneven. When pressed between the fingers, or cut with a knife, it emits a creaking sound, like artificial amalgam.

Geognostic and Geographic Situations.—Occurs in Deux-Ponts, and other mercury mines, along with cinnabar.

Genus VI.—SILVER.

Tessular. Ductile. Silver-white. Hardness = 2.5, —3.0. Sp. gr. 10.0, —10.5.

1. Hexahedral Silver.—Jameson.

Hexaedrisches Silber, *Mohs.*—Argent Natif, *Hauy.*

Specific Character.—Tessular. No cleavage.

Description.—Colour silver-white, and silver-white inclining to brass-yellow. Occurs regularly crystallized, massive, disseminated, dentiform, filiform, reticulated, and in leaves. Lustre metallic, and ranges from splendid to glimmering. Fracture hackly, Opaque.

The yellow varieties are named *auriferous native silver*, from their containing a portion of gold; the other varieties *common native silver*.

Geognostic and Geographic Situations.—Common native silver occurs in veins, generally occupying their middle or upper parts; and those veins traverse granite, gneiss, mica-slate, clay-slate, hornblende-slate, syenite, and porphyry in primitive mountains, and greywacke in transition mountains. It rarely occurs in secondary rocks, as in sandstone. The mines of Cornwall, Saxony, Hungary, Mexico, afford this mi-

neral in all its forms. The auriferous native silver was formerly found in the mines of Königsberg in Norway; and, at present, in those of Schlangenberg in Siberia.

Genus VII.—GOLD.

Tessular. Yellow. Hardness = 2.0, —2.5. Sp. gr. = 12.0, —20.0.

1. Hexahedral Gold.—Jameson.

Hexaedrisches Gediegen Gold, *Mohs.*—Gediegen Gold, *Werner.*—Or Natif, *Hauy.*

Specific Character.—Tessular. No cleavage.

Description.—Colours gold-yellow and brass-yellow. Occurs regularly crystallized, massive, disseminated, in flakes, in leaves, reticulated, capillary, dentiform, and in grains. Lustre shining, glistening, and metallic. Fracture hackly. Opaque.

The gold-yellow varieties are named *gold-yellow gold*; the brass-yellow varieties, *brass-yellow gold*; those varieties, in which the brass-yellow verges on steel-grey, are named *greyish-yellow gold*; and, lastly, the pale brass-yellow, inclining to silver-white, varieties are named *electrum*, or *argentiferous gold*.

Geognostic and Geographic Situations.—Occurs in veins, and disseminated in granite, syenite, gneiss, mica-slate, hornblende-slate, porphyry, greywacke, clay-slate, &c.; also in various alluvial deposits. The mines of Germany, Hungary, and America, afford examples of the various mineralogical and geological relations of this important mineral.

Genus VIII.—PLATINA.

Form unknown. Steel-grey. Hardness = 4.0, —4.5. Sp. gr. = 16.0, —20.0.

1. Native Platina.—Jameson.

Gediegen Platin, *Werner, Mohs.*—Platin Natif, *Hauy.*

Specific Character.—Form unknown. No Cleavage.

Description.—Colour pale steel-grey, approaching to silver-white. Occurs in flat grains and rolled pieces. Lustre shining and metallic.

Geognostic and Geographic Situations.—Occurs in alluvial soil, along with grains and loose crystals of chrome-ore, magnetic iron-ore, iron and copper pyrites, osmium, iridium, zircon, spinel, quartz, and native gold, in New Grenada, and Brazil in South America.

* *Osmium-Iridium.*—Colour steel-grey, slightly inclining to silver-white. Occurs in six-sided prisms, and in grains. Lustre shining and metallic. Harder than platina. Not malleable. Sp. gr. = 19.5.

Geognostic and Geographic Situations.—Occurs in the same districts in South America, and in the same alluvial formation as affords the platina.

** *Native Palladium.*—Colour steel-grey, inclining to silver-white. Occurs in loose grains. Lustre shining and metallic. Sp. gr. = 11.8, —12.14.

Geognostic and Geographic Situations.—Occurs along with platina in alluvial districts in Brazil.

Genus IX.—IRON.

Tessular. Pale steel-grey. Hardness 4.5. Sp. gr. = 7.4, —7.8.

1. *Octahedral Iron*.—Jameson.

Octaedrisches Eisen, Mohs.—Gediegen Eisen, *Werner*.—Fer Natif, *Haüy*.

Specific Character.—Tessular. No cleavage.

Description.—Colour pale steel-grey. Occurs ramose, and disseminated in meteoric stones. Lustre glimmering, glistening, and metallic. Fracture hackly.

Geographic Situation.—It is a meteoric production, and has been observed to fall from fireballs in Europe, Asia, and America.

N.B.—Native iron is mentioned as having been met with imbedded in graphite in the State of New York in America, and in metallic sulphurets in South America; and *native steel* is enumerated amongst the pseudo-volcanic productions of the department of Allier in France.

Genus X.—COPPER.

Tessular. Copper-red. Hardness = 2.5, — 3.0. Sp. gr. = 8.4, — 8.9.

1. *Octahedral Copper*.—Jameson.

Octaedrisches Kupfer, Mohs.—Gediegen Kupfer, *Werner*.

Specific Character.—Tessular. No cleavage.

Description.—Colour copper-red. Occurs regularly crystallized; massive, dendritic, capillary, botryoidal, and ramose. Lustre glistening and metallic. Fracture hackly.

Geognostic and Geographic Situations.—Occurs in granite, gneiss, mica-slate, clay-slate, primitive limestone, syenite, serpentine, greywacke, secondary limestone, sandstone, and generally in small veins; also in grains, and sometimes in blocks many pounds weight, in alluvial districts. It occurs in serpentine in Shetland, and in the copper mines of Cornwall. Large masses are met with in alluvial districts in the northern parts of North America.

Order X.—PYRITES.

Metallic lustre. Hardness = 3.5, — 6.5. Sp. gr. = 4.1, — 7.7. If hardness = 4.5, and less, the specific gravity is less than 5.0. If sp. gr. = 5.3, and less, the colour is yellow or red.

Genus I.—NICKEL PYRITES, or COPPER-NICKEL.

Prismatic. Hardness = 5.0, — 5.5. Sp. gr. = 7.5, — 7.7.

1. *Prismatic Nickel Pyrites*.—Jameson.

Prismatischer Nickel-kies, Mohs.—Kupfer-Nickel, *Werner*.—Nickel Arsenical, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage unknown. Copper-red.

Description.—Colour copper-red. Rarely crystallized; in granular distinct concretions; massive, disseminated, reticulated, dendritic, fruticose, globular, and botryoidal. Lustre shining and metallic. Fracture conchoidal. Brittle.

Geognostic and Geographic Situations.—Occurs in silver and cobalt veins in gneiss, mica-slate, clay-slate, and syenite; also in veins in secondary rocks, particularly bituminous marl-slate. In Scotland it is

met with at Leadhills and Wanlockhead, and in the coal-field of West Lothian.

* *Nickel Ochre*.—Colour apple-green. Occurs as a thin coating, seldom massive, and disseminated. Dull. Fracture uneven or earthy. Opaque, or translucent on the edges. Soft. Feels meagre. It occurs in mineral veins along with copper-nickel at Alva in Stirlingshire, in Linlithgowshire, and at Leadhills.

** *Black Nickel*.—Colour black. Occurs massive, disseminated, in crusts. Dull. Fracture earthy. Opaque. Soft. Shining in streak. Soils slightly. It occurs in veins in bituminous marl-slate at Riegelsdorf in Hesse.

Genus II.—ARSENIC PYRITES.

Prismatic. Hardness = 5.0, — 6.0. Sp. gr. = 5.7, — 7.4. If white, the sp. gr. = 6.2, and less. If grey, the sp. gr. above 6.8.

1. *Axotomous Arsenic Pyrites*.—Jameson.

Axentheilender Arsenik-kies, Mohs.—Arsenik-kies, *Werner*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage P = ∞. Less distinct P + ∞. (Fig 27, 30.) Pale steel-grey. Hardness = 5.0, — 5.5. Sp. gr. = 6.9, — 7.4.

Description.—Colour pale steel-grey. Occurs massive. Lustre metallic and shining.

Its locality unknown.

2. *Prismatic Arsenic Pyrites*.—Jameson.

Prismatischer Arsenik-kies, Mohs.—Arsenik-kies, *Werner*.—Fer Arsenical, *Haüy*.

Specific Character.—Prismatic. Pyramid = 154° 48'; 100° 34'; 84° 56'. P + ∞, 147° 3'. Cleavage P = ∞. (Pr + ∞)³ = 111° 19'. (Fig. 27, 32.) White, inclining to steel-grey. Hardness = 5.5, — 6.0. Sp. gr. = 5.7, — 6.2.

Description.—Colour silver-white. Occurs regularly crystallized; in prismatic concretions, massive and disseminated. Lustre ranges from splendid to glistening, and is metallic. Fracture uneven. Opaque. Brittle.

Geognostic and Geographic Situations.—This mineral occurs in a variety of metalliferous formations in primitive mountains, and also in those of the transition and secondary classes. In Scotland it occurs in secondary rocks in Stirlingshire, and in considerable quantity in the mines of Devon and Cornwall.

Genus III.—COBALT PYRITES.

Tessular. Hardness = 5.5. Sp. gr. = 6.0, — 6.6.

1. *Hexahedral Cobalt-Pyrites, or Silver-White Cobalt*.—Jameson.

Hexaedrischer Kobalt-kies, Mohs.—Glanz Kobold, *Werner*.—Cobalt gris, *Haüy*.

Specific Character.—Tessular. Combination semite ssular of parallel planes. Cleavage hexahedral and perfect. White, inclining to red. Hardness = 5.5. Sp. gr. = 6.1, — 6.3.

Description.—Colour silver-white, inclining to copper-red. Occurs regularly crystallized; in granular distinct concretions, massive, disseminated.

Mineralogy. and reticulated. Lustre shining, glistening, and metallic. Fracture conchoidal. Brittle. Easily frangible.

Geognostic and Geographic Situations.—Occurs in beds, in mica slate, associated with iron and copper-pyrites, magnetic iron-ore, anthophyllite, tourmaline, felspar, &c. in parish of Modum, in Norway, also at Tunaberg, in Sweden. In some transition districts it is found in veins along with various ores of iron and copper.

2. Octahedral Cobalt-Pyrites, or Tin-White Cobalt.—Jameson.

Octaedrischer Cobalt-kies, *Mohs.*—Weisser Speiskobald, *Werner.*—Cobalt Arsenical, *Haüy.*

Specific Character.—Tessular. Cleavage hexahedral, octahedral, dodecahedral, but very indistinct; sometimes the hexahedral is more distinct. Tin-white, inclining to steel-grey. Hardness = 5.5. Sp. gr. = 6.0, —6.6.

Description.—Colour tin-white, inclining to steel-grey. Occurs regularly crystallized; in lamellar and granular concretions; massive, disseminated, reticulated, fruticose, specular. Lustre shining, splendid, and metallic. Fracture uneven. Brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in veins in primitive and transition rocks; also in old red sandstone, and in copper-slate. Cornwall, Hesse, Thuringia, Hartz, &c. afford many localities of this mineral.

* Grey Cobalt Pyrites.—Jameson.

Grauer Speisskobalt, *Werner.*—Cobalt Arsenical Amorphe, *Haüy.*

On the fresh fracture is steel-grey, but on exposure becomes greyish-black. Occurs massive, tubiform, and specular. Lustre glimmering, glistening, and metallic, but the specular variety is splendid. Fracture uneven, conchoidal, or even. Brittle. Shining in streak. Same hardness as hexahedral cobalt-pyrites. Brittle. Sp. gr. = 7.0. Occurs in veins in primitive rocks in Cornwall.

** Cobalt-Kies.—Haussmann.

Colour pale steel-grey, which on exposure becomes nearly copper-red. Occurs massive, disseminated, and in cubes. Lustre shining and metallic. Fracture uneven or conchoidal. Semihard. Occurs in a bed of copper pyrites in gneiss, at Riddarhyttan, in Sweden.

*** Radiated Tin-white Cobalt Pyrites.—Jameson.

Strahliger Weisser Speisskobald, *Werner.*

Colour tin-white, passing into steel-grey. Occurs massive, disseminated, and reniform; also in scopiform and stellular radiated, and fibrous concretions. Lustre glistening and metallic. Fracture uneven. Softer than octahedral cobalt pyrites. Occurs in Saxony and Norway, but is a rare mineral.

Genus IV.—IRON PYRITES.

Tessular, rhomboidal, prismatic. Yellow. Hardness = 3.5, —6.5. Sp. gr. = 4.4, —5.0.

1. Hexahedral Iron-Pyrites.—Jameson.

Miscrology.

Hexaedrischer Eisen-Kies, *Mohs.*—Gemeiner Schwefel-Kies, *Werner.*—Fer Sulphure, *Haüy.*

Specific Character.—Tessular. Combination, semi-tessular of parallel planes. Bronze-yellow. Hardness = 6.0, —6.5. Sp. gr. = 4.7, —5.0.

Description.—Colour bronze-yellow, sometimes inclining to steel-grey. Occurs regularly crystallized; in granular concretions, massive, disseminated, globular, and cellular. Lustre ranges from shining to glimmering, and is metallic. Fracture uneven and conchoidal. Opaque. Brittle.

Geognostic and Geographic Situations.—The cellular varieties are rare, and hitherto have been met with principally in Saxony; while the others occur in all countries, and more or less extensively distributed through rocks of every description, from those of the oldest primitive, to the newest alluvial formations.

2. Prismatic Iron Pyrites.—Jameson.

Prismatischer Eisenkies, *Mohs.*—Fer Sulphure Blanc, *Haüy.*

Specific Character.—Prismatic. Pyramid = $115^{\circ} 58'$; $89^{\circ} 11'$; $125^{\circ} 16'$. Cleavage, $P + \infty = 106^{\circ} 36'$. (Fig. 30.) Colour bronze-yellow. Hardness = 6.0, —6.5. Sp. gr. = 4.7, —5.0.

Description.—Colour bronze-yellow, inclining sometimes to steel-grey, or to brass-yellow. Occurs regularly crystallized; in radiated, granular, and lamellar concretions; massive, dendritic, reniform, globular, stalactitic, botryoidal, fruticose, and with impressions. Lustre varies from glistening to glimmering, and is metallic. Opaque. Brittle. Easily frangible.

The varieties in radiated concretions are named *radiated pyrites*; those in which the colour inclines to brass-yellow, and which, on exposure to air, acquire a brown tarnish, are named *hepatic pyrites*; those in spear-shaped twin and triple crystals, *spear-pyrites*; and lastly, those in which the crystals are so aggregated as to have the form of the comb of the cock, are named *cockscorn-pyrites*.

Geognostic and Geographic Situations.—This species of iron-pyrites occurs more frequently and abundantly in newer than in older formations. The newest secondary formations, and those of the alluvial class, both in this island and on the continent of Europe, afford numerous localities of the radiated varieties. The spear-pyrites is met with in Bohemia and Saxony; and the cockscorn-pyrites in veins in Derbyshire, and in some mines in Saxony.

3. Rhomboidal Iron-Pyrites.—Jameson.

Rhomboedrischer Eisenkies, *Mohs.*—Magnetkies, *Werner.*—Fer Sulphuré Ferrifère, *Haüy.*

Specific Character.—Rhomboidal. Rhomboid unknown. Combination di-rhomboidal. Cleavage, $R = \infty$. Less distinct $P + \infty$. Colour bronze-yellow, inclining to copper-red. Hardness = 3.5, —4.5. Sp. gr. 4.4, —4.7.

Description.—Colours intermediate between bronze-yellow and copper-red. Occurs rarely crystallized; in granular concretions, also massive and dis-

Mineralogy.—seminated. Lustre ranges from splendid to glistening, and is metallic. Fracture conchoidal and uneven. Opaque. Brittle. Easily frangible.

Geognostic and Geographic Situations.—This mineral occurs disseminated in primitive and transition rocks, and also disposed in beds in rocks of the same classes, in Scotland, England, Saxony, &c.

Genus V.—COPPER PYRITES.

Pyramidal. Hardness = 3.5, —4.0. Sp. gr. = 4.1, —4.3.

1. *Pyramidal Copper-Pyrites, or Yellow Copper-Pyrites*.—Jameson.

Pyramidaler Kupfer-kies, *Mohs*.—Kupfer-kies, *Werner*.—Cuivre pyriteux, *Hauy*.

Specific Character.—Pyramidal. Pyramid 109° 53'; 108° 40'. Combination hemi-pyramidal, of inclined planes. Cleavage, $P+1=101^\circ 49'$; $126^\circ 11'$. Brass-yellow.

Description.—Colour brass-yellow. Occurs regularly crystallized; massive, disseminated, in flakes, dendritic, reniform, botryoidal, stalactitic, and specular. Internally shining, glimmering, and metallic. Fracture uneven and conchoidal. Brittle, and easily frangible.

Geognostic and Geographic Situations.—This species of pyrites is found in all the great classes of rocks, and not only in veins, but also in beds, and in vast imbedded masses. The copper mines in England afford it in great variety and abundance; and it occurs also in Scotland, but in smaller quantities.

UNDETERMINED PYRITES.

1. *Nickeliferous Grey Antimony*.

Antimoine Sulphure Nickelifer, *Hauy*.

Tessular. Cleavage, hexahedral, perfect. Metallic lustre. Colour steel-grey, somewhat inclining to silver-white. Hardness = 5.0, —5.5. Sp. gr. = 6.4, —6.6. Occurs in veins along with galena, sparry-iron, and copper-pyrites, in the principality of Nassau.

2. *Tin-Pyrites*.

Etain Sulphuré, *Hauy*.

Colour intermediate between steel-grey and brass-yellow. Occurs massive, and disseminated. Internally glistening, shining, and metallic. Fracture uneven, inclining to conchoidal. Brittle, and easily frangible. Hardness = 4.0. Sp. gr. = 4.350, *Klaproth*. Occurs in copper mines in Cornwall.

Order XI.—GLANCE.

Lustre metallic. Grey, black. Hardness = 1.0, —4.0. Sp. gr. = 4.0, —7.6. If sp. gr. under 5.0, and cleavage monotonous, the colour is lead-grey. If sp. gr. above 7.4, the colour is lead-grey.

Genus I.—COPPER-GLANCE.

Tessular, prismatic. Hardness = 2.5, 4.0. Sp. gr. = 4.4, —5.8. If sp. gr. above 5.0, the colour is blackish-lead-grey. If sp. gr. under 5.0, it is steel-grey, or black.

1. *Tetrahedral Copper-Glance*.—Jameson.

Tetraedrischer Kupfer-glanz, *Mohs*.—Fahlerz. Schwarzerz, *Werner*.—Cuivre gris, *Hauy*.

Specific Character.—Tessular. Combination semi-tessular of inclined planes. Cleavage, octahedral. Colour steel-grey, ... iron-black. Hardness = 3.0, —4.0. Sp. gr. = 4.4, —4.9.

Description.—Colour steel-grey, and iron-black. Occurs regularly crystallized, massive, and disseminated. Lustre externally splendid and metallic, internally shining, or glistening, and metallic. Fracture conchoidal or uneven. Opaque, brittle, and easily frangible.

The grey varieties are named *grey copper*; the black, *black copper*.

Geognostic and Geographic Situations.—The grey varieties occur in veins in transition granite, and syenite, at Fasseney Burn, in East-Lothian; at Airthrie, in Stirlingshire; in Ayrshire, and in Devonshire. The black varieties are found in transition rocks, at Claasthal, in the Hartz.

2. *Prismatoidal Copper-Glance*.—Jameson.

Prismatoidischer Kupfer-glanz, *Mohs*.—Prismatic Antimony Glance, *J*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $Pr+\infty$. (Fig. 29.) Blackish lead-grey. Brittle. Hardness = 3.0. Sp. gr. = 5.7, —5.8.

Description.—Colour blackish lead-grey. Crystals in oblique four-sided prisms. Lustre shining and metallic.

3. *Prismatic Copper-Glance, or Vitreous Copper*.—Jameson.

Prismatischer Kupfer-glanz, *Mohs*.—Kupferglas, *Werner*.—Cuivre Sulphuré, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P+\infty=120^\circ$ (nearly). $Pr+\infty$. (Fig. 30, 29.) Sectile in a high degree. Blackish lead-grey. Hardness = 2.5, —3.0. Sp. gr. = 5.5, —5.8.

Description.—Colour blackish lead-grey. Occurs regularly crystallized, also in granular concretions, and massive. Lustre glistening, glimmering, and metallic. Fracture conchoidal and uneven. Opaque. Sectile, and rather easily frangible.

Geognostic and Geographic Situations.—Occurs in veins at Fasseney Burn; in the rocks of Fair Isle; in Yorkshire, Caernarvonshire, and Cornwall.

* *Variegated Copper*.—Jameson.

Buntkupfererz, *Werner*.—Cuivre Pyriteux Hepatique, *Hauy*.

Colour between copper-red and pinchbeck-brown, but soon obtains a variegated tarnish. Occurs in cubes truncated on the angles, and massive. Lustre shining and metallic. Cleavage octahedral. Fracture conchoidal. Sp. gr. = 5.03.

Geognostic and Geographic Situations.—Occurs in veins in primitive, transition, and secondary rocks. Found in Cornwall and other mining districts.

** *Argentiferous Copper-Glance*.

Silber Kupfer-glanz, *Hausmann*.

Mineralogy.

Mineralogy. Colour blackish lead-grey. Massive, and disseminated. Internally shining or glistening, and metallic. Fracture flat, conchoidal. Lustre increased in the streak. Soft. Sectile. Rather difficultly frangible. Sp. gr. = 6.255, *Stromeyer*. Occurs along with copper-pyrites, calcareous spar, and hornstone, at Schlangenbergr, in Siberia.

*** *Plumbiferous Copper-Glance.*

Bleifahlerz, *Hausmann*.

Prismatic. Cleavage, P—∞. Less distinct, P+∞ = 95° (nearly). Pr+∞. Pr+∞. Metallic lustre. Steel-grey, inclining to lead-grey. Hardness = 2.5,—3.0. Sp. gr. = 5.7,—5.8. Occurs in veins that traverse clay-slate in the Hartz.

**** *Tennantite.*—*Phillips*.

Tessular. Cleavage, dodecahedral. Colour lead-grey, inclining to iron-black. Streak reddish-grey. Hardness = 4.0. Sp. gr. = 4.375, *Phillips*. Occurs in veins of copper-ore in Cornwall.

***** *Eukairite, or Seleniferous Copper-Glance.*—*Berzelius*.

Colour lead-grey. Occurs massive. Lustre shining and metallic. Fracture fine grained, uneven. Opaque. Soft. Can be cut with the knife, and receives an impression from the hammer. Streak shining. Powder of streak-grey. This remarkable copper-glance, which contains twenty-six parts of the new metal named Selenium, occurs in an old copper mine in Smaland, in Sweden.

Genus II.—SILVER GLANCE, or VITREOUS SILVER.

Silber-glanz, *Mohs*.

Tessular. Blackish lead-grey. Hardness = 2.0,—2.5. Sp. gr. = 6.9,—7.2.

1. *Hexahedral Silver-Glance.*—*Jameson*.

Hexaedrischer Silber-glanz, *Mohs*.—*Glaserz, Werner*.—*Argent Sulphuré, Haüy*.

Specific Character.—Tessular. Cleavage not discernible. Malleable.

Description.—Colour blackish lead-grey. Occurs regularly crystallized; massive, disseminated, in plates, dentiform, filiform, capillary, reticulated, dendritic, stalactitic, and with impressions. Lustre shining, glistening, and metallic. Fracture uneven or conchoidal. Completely malleable. Flexible, but not elastic.

Geognostic and Geographic Situations.—It is one of the most common of the ores of silver. It was formerly met with at Airthrie in Stirlingshire, and is still found in the mines of Cornwall.

Genus III.—GALENA, or LEAD-GLANCE.

Tessular. Pure lead-grey. Hardness = 2.5. Sp. gr. = 7.0,—7.6.

1. *Hexahedral Galena, or Lead-Glance.*—*Jameson*.

Hexaedrischer Bleiglanz, *Mohs*.—*Bleiglanz, Werner*.—*Plomb sulphuré, Haüy*.

Specific Character.—Tessular. Cleavage, hexahedral.

Description.—Colour lead-grey. Occurs regularly crystallized; in granular, prismatic, and lamellar concretions; massive, disseminated, specular, reticulated, botryoidal, and corroded. Lustre splendid to glimmering and metallic. Fracture even, or flat conchoidal. Fragments cubical. Sectile. Uncommonly easily frangible.

The variety with glimmering lustre, and even or conchoidal fracture, is named *compact galena*.

Geognostic and Geographic Situations.—This mineral, which is the species from which all the lead of commerce is obtained, occurs in every lead mine, whether in primitive, transition, or secondary rocks.

* *Blue Lead.*—*Jameson*.

Blau Bleierz, *Werner*.

Description.—Colour between dark indigo-blue and dark lead-grey. Occurs massive, and in six-sided prisms. Is glimmering and metallic. Fracture uneven, or small conchoidal. Opaque. Streak shining. Sectile, and easily frangible. Is rare, and hitherto has been found principally in lead mines in Saxony and France.

Genus IV.—TELLURIUM-GLANCE, or BLACK TELLURIUM.

Tellur-Glanz, *Mohs*.

Prismatic. Cleavage, montomous. Hardness = 1.0,—1.5. Sp. gr. = 7.0,—7.2.

1. *Prismatic Tellurium-Glance.*—*Jameson*.

Prismatischer Tellur-glanz, *Mohs*.—*Nagyagerz, Werner*.—*Tellure natif auro-plombifère, Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, axotomous, or prismatoidal, and very perfect. Blackish lead-grey. Iron black.

Description.—Colour blackish lead-grey, and iron-black. Occurs regularly crystallized; massive, disseminated, and in leaves. Lustre splendid and metallic. Sectile.

Geognostic and Geographic Situations.—Occurs in veins that traverse porphyry, in Transylvania.

Genus V.—MOLYBDENA, or MOLYBDENA-GLANCE.

Molybdän-Glanz, *Mohs*.

Rhombohedral. In thin leaves. Easily flexible. Hardness = 1.0,—1.5. Sp. gr. = 4.4,—4.6.

1. *Rhombohedral Molybdena.*—*Jameson*.

Rhomboedrischer Molybdän, *Mohs*.—*Wasserblei, Werner*.—*Molybdene sulphuré, Haüy*.

Specific Character.—Rhombohedral. Rhomboid unknown. Combination di-rhombohedral. Cleavage R—α, perfect. Pure lead-grey.

Description.—Colour fresh lead-grey. Occurs regularly crystallized; massive, disseminated, in plates, and in granular concretions. Lustre splendid or shining and metallic. Sectile, approaching to malleable.

Geognostic and Geographic Situations.—Occurs imbedded in granite and syenite at Peterhead; in chlorite-slate in Glenelg; in granite and syenite in Corybue, at the head of Loch Creran, and in various mines in Cornwall.

Mineralogy.

• *Molybdena Ochre*.—Jameson.

The sulphur yellow mineral which sometimes incrusts molybdena is named *molybdena ochre*.

Genus VI.—BISMUTH-GLANCE.

Prismatic. Pure lead-grey. Hardness = 2.0, — 2.5. Sp. gr. = 6.1, — 6.4.

1. *Prismatic Bismuth-Glance*.—Jameson.

Prismatischer Wismuth-Glanz, *Mohs*.—Wismuth-Glanz, *Werner*.—Bismuth sulphurè, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown.

Cleavage $P + \infty$. $Pr + \infty$. $Pr + \infty$. (Fig. 30, 29, 28.)

Description.—Colour pale lead-grey. Occurs regularly crystallized; in granular and radiated concretions; massive and disseminated. Internally splendid and metallic. Soils. Brittle, inclining to sectile. Easily frangible.

Geognostic and Geographic Situations.—Occurs in veins in Cornwall.

• *Bismuth Ochre*.—Jameson.

Wismuth-ocker, *Werner*.

The yellow, grey, or green mineral which sometimes accompanies bismuth-glance, is the bismuth ochre of mineralogists.

Genus VII.—ANTIMONY GLANCE.

Antimon-Glanz, *Mohs*.

Prismatic. Hardness = 1.5, — 2.5. Sp. gr. = 4.0, — 5.8. If Sp. gr. under 5.0, the hardness = 2.0, and if sp. gr. above 5.0, the colour is steel-grey.

1. *Prismatic Antimony-Glance*.—Jameson.

Prismatischer Antimon-glanz, *Mohs*.—Schrift-crz, *Werner*.—Tellure natif auro-argentifère, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $Pr + \infty$, perfect. Less distinct, $Pr + \infty$. (Fig. 29, 28.) Pure steel-grey. Hardness = 1.5, — 2.0. Sp. gr. = 5.7, — 5.8.

Description.—Colour steel-grey. Occurs regularly crystallized; massive, disseminated, and in leaves. Externally splendid, internally glistening, and metallic. Fracture uneven. Rather brittle.

Geognostic and Geographic Situations.—Occurs in porphyry veins in Transylvania.

2. *Prismatoidal Antimony-Glance, or Grey Antimony*.—Jameson.

Grau Spiesglaserz, *Werner*.—Prismatoidischer Antimon-Glanz, *Mohs*.—Antimoine sulphurè, *Hauy*.

Specific Character.—Prismatic. Pyramid 110° 58'; 107° 56'; 109° 24'. Cleavage, $Pr + \infty$, perfect. Less distinct, $P - \infty$. $P + \infty = 92^\circ 10'$. $Pr + \infty$. (Fig. 29, 27, 30, 28.) Lead-grey. Hardness = 2.0. Sp. gr. = 4.0, — 4.6.

Description.—Colour lead-grey. Occurs regularly crystallized, in radiated, fibrous, and granular distinct concretions. Lustre ranges from glistening to splendid, and is metallic. Fracture even and uneven. Rather brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in

veins that traverse greywacke, at Westerhall, in Dumfries-shire, and in Banffshire in primitive rocks.

3. *Azotomous Antimony-Glance, or Bournonite*.—Jameson.

Axentheilender Antimon-Glanz, *Mohs*.—Triple Sulphurè d'Antimoine, Plomb et Cuivre; Endellionc, Bournon.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P - \infty$, very perfect. (Fig. 27.) Steel-grey. Hardness = 2.0, — 2.5. Sp. gr. = 5.5, — 5.8.

Description.—Colour steel-grey. Occurs regularly crystallized, and massive. Lustre externally shining, internally glistening, and metallic. Fracture uneven or conchoidal. Opaque. Very brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in veins in clay-slate in Cornwall.

Genus VIII.—MELANE-GLANCE.

Prismatic. Black, partly inclining to lead-grey. Hardness = 2.0, — 3.0. Sp. gr. = 5.9, — 6.6.

1. *Diprismatic Melane-Glance, or Black Antimony-Ore*.—Werner, Jameson.

Diprismatischer Melan-Glanz, *Mohs*.—Schwarz Spiesglaserz, *Werner*.—Plomb Sulphurè-Antimoni-fère, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $Pr + \infty$. $Pr + \infty$, the latter somewhat more discernible, but both imperfect. (Fig. 28, 29.) Iron-black, inclining to lead-grey. Hardness = 2.5, — 3.0. Sp. gr. = 6.4, — 6.6.

Description.—Colour iron-black, inclining more or less to steel-grey. Occurs regularly crystallized, and massive. Lustre shining, splendid, and metallic. Fracture conchoidal. Rather brittle, and easily frangible.

Geognostic and Geographic Situations.—Occurs in veins in primitive and transition rocks, in Transylvania and Saxony.

2. *Prismatic Melane-Glance, or Brittle Silver-Glance*.—Jameson.

Prismatischer Melan-Glanz, *Mohs*.—Sprödglasserz, *Werner*.—Argent Antimoine-Sulphurè Noire, *Hauy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage, $P + \infty = 124^\circ$ (nearly). $Pr + \infty$, imperfect. (Fig. 30, 29.) Iron-black. Hardness = 2.0, — 2.5. Sp. gr. = 5.9, — 6.4.

Description.—Colour between iron-black and dark lead-grey. Occurs regularly crystallized and disseminated. Lustre externally splendid, internally shining, and metallic. Fracture conchoidal and uneven.

Geognostic and Geographic Situations.—Occurs in veins in primitive rocks in Hungary.

Order XII.—BLENDE.

Hardness = 1.0, — 4.0. Sp. gr. = 3.9, — 8.2. If the lustre is metallic, the colour is black. If the lustre is not metallic, it is adamantine. If the streak is brown, white, or grey, the sp. gr. is between 4.0,

Mineralogy. and 4.2, and the form tessular. If the streak is red, the sp. gr. = 4.5, and more; and the hardness = 2.5, and less. If the sp. gr. = 4.3, and more, the streak is red.

Genus I.—MANGANESE-BLENDE.

Glanz-Blende, *Mohs*.—Mangan-Blende, *Werner*.

Prismatic. Streak green. Hardness = 3.5, —4.0. Sp. gr. = 3.9, —4.0.

1. Prismatic Manganese-Blende.—Jameson.

Prismatisches Glanz-Blende, *Mohs*.—Manganese Sulphuré, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage prismatic. Metallic aspect.

Description.—Colour iron-black, which, on exposure, becomes brownish-black. Occurs regularly crystallized, in granular concretions, massive, and disseminated. Lustre splendid, shining, and metallic, inclining to imperfect metallic. Opaque. Streak greenish-grey.

Geognostic and Geographic Situations.—Occurs in Cornwall and in Transylvania in primitive and transition rocks.

Genus II.—ZINC-BLENDE, or GARNET-BLENDE.

Granat-Blende, *Mohs*.

Tessular. Streak grey, white, reddish brown. Hardness = 3.5, —4.0. Sp. gr. = 4.0, —4.2.

1. Dodecahedral Zinc-Blende.—Jameson.

Dodecaedrische Granat-Blende, *Mohs*.—Blende, *Werner*.—Zinc Sulphuré, *Haüy*.

Specific Character.—Tessular. Combination, semi-tessular of inclined planes. Cleavage dodecahedral.

Description.—Colours brown, yellow, grey, green, red, and black. Occurs regularly crystallized, also in granular and fibrous distinct concretions, massive, and disseminated. Lustre ranges from specular splendid to glimmering, and is adamantine. Ranges from transparent to opaque. Brittle, and easily frangible.

The varieties in which the yellow colours predominate are named *yellow zinc-blende*; those in which the brown colour predominate *brown zinc-blende*; and, lastly, those in which black is the characteristic colour are named *black zinc-blende*.

Geognostic and Geographic Situations.—Beautiful yellow varieties are met with in the old lead mines of Tyndrum in Perthshire; the brown, or common blende, in every lead mine in England and Scotland; while the black variety, which is the rarest, occurs in small quantity in Saxony, and some other mining countries on the Continent of Europe.

Genus III.—ANTIMONY-BLENDE, or RED ANTIMONY.

Purpur-Blende, *Mohs*.

Prismatic. Hardness = 1.0, —1.5. Sp. gr. = 4.5, —4.6.

1. Prismatic Antimony-Blende, or Red Antimony.

Prismatische Purpur-Blende, *Mohs*.—Roth Spiesglas-erz, *Werner*.—Antimoine Oxydé Sulphuré, *Haüy*.

Specific Character.—Prismatic. Pyramid unknown. Cleavage prismatoidal. Streak cherry-red.

Description.—Colour cherry-red, and frequently with a tempered-steel tarnish. Occurs regularly crystallized; in granular, and scopiform, and stellate fibrous concretions. Lustre shining and adamantine. Opaque, or translucent on the edges.

Geognostic and Geographic Situations.—Occurs in small quantity in primitive rocks, in Saxony, France, and Ilungary.

Genus IV.—RUBY-BLENDE.

Rubin-Blende, *Mohs*.

Rhombohedral. Hardness = 2.0, —2.5. Sp. gr. = 5.2, —8.2.

1. Rhombohedral Ruby-Blende, or Red Silver.—Jameson.

Romboedrische Rubin-Blende, *Mohs*.—Rothgiltigerz, *Werner*.—Argent Antimoine Sulphuré, *Haüy*.

Specific Character.—Rhombohedral. Rhomboid = 109° 28'. Combination sometimes with different planes on opposite extremities. Cleavage, rhombohedral. Streak cochineal-red. Hardness = 2.5. Sp. gr. = 5.2, —5.8.

Description.—Colour between cochineal-red and dark lead-grey, and sometimes inclines to carmine-red. Occurs regularly crystallized; massive and disseminated. Lustre ranges from splendid to glimmering, and is adamantine. Fracture uneven or conchoidal. Ranges from opaque to transparent.

Geognostic and Geographic Situations.—In some silver mines it is an abundant ore, and in this country has been hitherto found only in Cornwall.

2. Peritomous Ruby-Blende, or Cinnabar.—Jameson

Rubin-Blende, *Mohs*.—Mercure Sulphuré, *Haüy*.

Specific Character.—Rhombohedral. Rhomboid = 71° 48'. Cleavage, $R + \infty$, perfect. Streak scarlet-red. Hardness = 2.0, —2.5. Sp. gr. = 6.7, —8.2.

Description.—Colours cochineal and scarlet-red, and sometimes inclines to dark steel-grey. Occurs regularly crystallized; in granular and globular concretions; massive, disseminated, and dendritic. Lustre ranges from splendid to glimmering, and is adamantine, verging on semi-metallic. Fracture uneven, conchoidal, and earthy. Ranges from transparent to opaque. Sectile, and easily frangible.

The dark-coloured varieties, inclining to steel-grey, are named *hepatic cinnabar*, the others *common cinnabar*.

Geognostic and Geographic Situations.—Common cinnabar and hepatic cinnabar are the minerals that afford all the mercury of commerce. The first occurs in beds, and imbedded in porphyry rocks and those of the coal formation, while the other appears to be entirely confined to those of the coal formation. The mercury mines of Idria, Almadin, and of Deux-Ponts, afford all the known varieties of this important metalliferous mineral.

Order XIII.—SULPHUR.

No metallic lustre. Colour yellow, red or brown. Prismatic. Hardness = 1.0, —2.5. Sp. gr. = 1.9,

Mineralogy. 3.6. If sp. gr. above 2.1, the streak is yellow or red.

Genus I.—SULPHUR.

Prismatic. Hardness = 1.5, —2.5. Sp. gr. = 1.9, —3.6.

1. *Prismatoidal Sulphur, or Yellow Orpiment.*—Jameson.

Prismatoidischer Schwefel, *Mohs.*—Gelb-Rausch gelb, *Werner.*—Arsenic Sulphur, *Haüy.*

Specific Character.—Prismatic. Pyramid unknown. Cleavage, distinctly prismatoidal. Streak lemon-yellow. Hardness = 1.5, —2.0. Sp. gr. = 3.4, —3.6.

Description.—Colour lemon-yellow. Occurs regularly crystallized; in granular and concentric lamellar concretions; massive, disseminated, stalactitic, reniform, botryoidal, and in crusts. Lustre splendid, between adamantine and semi-metallic. Translucent. Sectile. Flexible, but not elastic.

Geognostic and Geographic Situations.—Occurs in veins in various metalliferous formations in primitive and secondary rocks in Hungary and Germany.

2. *Hemi-prismatic Sulphur, or Red Orpiment.*—Jameson.

Hemiprismatischer Schwefel, *Mohs.*—Roth-Rausch gelb, *Werner.*—Arsenic Sulphur, *Haüy.*

Specific Character.—Prismatic. Pyramid = $138^{\circ} 15'$; $121^{\circ} 35'$; $74^{\circ} 21'$. Combination hemi-prismatic.

$\frac{P}{2} = 121^{\circ} 35'$. Cleavage, $\frac{Pr}{2}$. Less distinct, $P + \infty = 72^{\circ} 17'$. $Pr + \infty$. (Inclination of $\frac{Pr}{2}$ to $Pr + \infty = 114^{\circ} 6'$) (Fig. 36, 30, 28.)

Streak orange-yellow . . . morning-red. Hardness = 1.5, —2.0. Sp. gr. = 3.3, —3.4.

Description.—Colour aurora-red, inclining sometimes to orange-yellow. Occurs regularly crystallized; massive, disseminated, and in flakes. Lustre shining, and adamantine. Fracture uneven. Translucent and semi-transparent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—Generally occurs in veins in primitive rocks, and sometimes also in those of secondary formations in Germany and other countries.

3. *Prismatic Sulphur, or Common Sulphur.*—Jameson.

Prismatischer Schwefel, *Mohs.*—Naturlicher Schwefel, *Werner.*—Soufre, *Haüy.*

Specific Character.—Prismatic. Pyramid = $107^{\circ} 19'$; $84^{\circ} 24'$; $143^{\circ} 8'$. Cleavage, $P.P + \infty = 102^{\circ} 41'$. (Fig. 30.) Streak white or sulphur-yellow. Hardness = 1.5, —2.5. Sp. gr. = 1.9, —2.1.

Description.—Colours yellow, brown, and grey. Occurs regularly crystallized; in granular distinct concretions; massive, disseminated, stalactitic, vesicular, and corroded. Lustre ranges from shining to glimmering, and is between adamantine and resinous. Fracture uneven, splintery, or conchoidal.

Translucent and transparent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—This mineral occurs in considerable quantities, along with gypsum, in secondary rocks in Spain and other countries; also in alluvial formations in the vicinity of sulphureous springs, and is very abundantly formed in some active volcanoes in Italy and Iceland.

CLASS III.

Specific gravity under 1.8. If liquid, the smell is bituminous. If solid, is tasteless.

Order I.—RESIN.

Hardness = 0, —2.5. Sp. gr. = 0.7, —1.6. If sp. gr. = 1.2, and more, the streak is white or grey.

Genus I.—MELLITE, or HONEY-STONE.

Melichron-Resin, *Mohs.*

Pyramidal. Hardness = 2.0, —2.5. Sp. gr. = 1.4, —1.6.

1. *Pyramidal Mellite, or Honey-Stone.*—Jameson.

Pyramidales Melichron-Resin, *Mohs.*—Honigstein, *Werner.*—Mellite, *Haüy.*

Specific Character.—Pyramidal. Pyramid = $118^{\circ} 4'$, — $93^{\circ} 22'$. Cleavage pyramidal, but imperfect.

Description.—Colours yellow or red. Occurs regularly crystallized and massive. Lustre shining or splendid, and vitreo-resinous. Fracture conchoidal, semi-transparent, or translucent. Brittle.

Geognostic and Geographic Situations.—This rare and remarkable mineral has hitherto been found only associated with brown coal at Artern in Thuringia.

Genus II.—MINERAL-RESIN.

Erd-harz, *Mohs.*

Amorphous. Hardness = 0.0, —2.5. Sp. gr. = 0.8, —1.2.

1. *Yellow Mineral-Resin or Amber.*—Jameson.

Gelbes Erd-harz, *Mohs.*—Bernstein, *Werner.*—Succin, *Haüy.*

Specific Character.—Solid. Yellow...white. Streak white or grey. Hardness = 2.0, —2.5. Sp. gr. = 1.0, —1.1.

Description.—Colours yellow and white. Occurs massive and disseminated, and often incloses insects, leaves, and other parts of vegetables, also corals, &c. Lustre ranges from splendid to glistening, and is resinous. Fracture conchoidal. Transparent and translucent. Brittle, and easily frangible.

Geognostic and Geographic Situations.—This beautiful mineral occurs in greatest abundance and variety imbedded in the various strata of the alluvial class, and the finest masses are those found in the low, flat, and alluvial countries on the shores of the Baltic. It has been sometimes gathered on the coasts of Scotland and England.

2. *Black Mineral-Resin.*—Jameson.

Schwarzes Erd-harz, *Mohs.*—Bitume, *Haüy.*

Specific Character.—Solid...liquid. Black, brown, red, and grey. Streak black, brown, yellow, and grey. Hardness = 0.0, —2.0. Sp. gr. = 0.8, —1.2.

Description.—Colours white, grey, yellow, brown,

and black. Occurs massive, disseminated, globular, reniform, stalagmitic, and liquid. Lustre resinous, and ranging from splendid to glimmering. Fracture earthy, conchoidal, and slaty. Ranges from transparent to opaque.

The yellowish-white, yellowish-grey, and wine-yellow, liquid transparent varieties are named *naphtha*; the blackish-brown, liquid, and translucent or opaque varieties are named *mineral ore*, or *petroleum*; the blackish-brown solid varieties, with earthy fracture, are described under the name *Earthy Mineral-pitch*; the pitch-black varieties, with splendid and shining lustre and conchoidal fracture, are the *slaggy mineral-pitch*, or *asphaltum* of authors; and lastly, the brown, massive, curved slaty, and elastic varieties are named *elastic mineral-pitch*.

Geognostic and Geographic Situations.—The naphtha and mineral-oil flow from rocks of limestone and of the coal formations. The finest varieties of the former are found on the shores of the Caspian, the latter occurs at St Catharine's, in the vicinity of Edinburgh, and in several other places in Scotland and England. The earthy mineral pitch is a rare mineral, and has been hitherto found principally in the Harz; the slaggy mineral-pitch is met with imbedded in the limestone, ironstone, and sandstone of the coal formation in the middle district of Scotland; and the elastic mineral-pitch has been hitherto found only in the lead mine called Odin, to the north of Castletown in Yorkshire.

Order II.—COAL.

Streak brown and black. Hardness = 1.0, — 2.5. Sp. gr. = 1.2, — 1.5.

Genus I.—MINERAL COAL.

Amorphous. Hardness = 1.0, — 2.5. Sp. gr. = 1.2, — 1.5.

1. Bituminous Mineral-Coal.—Jameson.

Harzige Stein-kohle, *Mohs*.

Specific Character.—Colours black and brown. Resinous lustre. Bituminous smell. Hardness = 1.0, — 2.5. Sp. gr. = 1.2, — 1.5.

Description.—Colours brown, black, and grey. Occurs massive, ligniform, and rarely in columnated concretions. Lustre ranges from splendid to glimmering, and is resinous. Fracture earthy, conchoidal, slaty, and uneven. Opaque. Streak shining. Sectile or brittle. Easily frangible.

These varieties of bituminous coal, in which brown is the predominating colour, with feeble lustre, more or less of the woody texture or form, and easily frangible, are named *brown coal*, under which division is included the *fibrous*, *earthy*, *aluminous*, *conchoidal*, and *trapezoidal brown-coal* of authors. The varieties in which the black colour predominates, and the resinous lustre, is considerable, and which are harder than the brown varieties, are named *black-coal*, of which the following kinds are enumerated by mineralogists, viz. *lustrous-coal*, *canal-coal*, *foliated-coal*, and *coarse-coal*.

Geognostic and Geographic Situations.—The brown coal occurs principally along with rocks of the alluvial class, and the coal of Bovey in England may serve as an example of it in this island; the black-

coal never occurs in alluvial formations, always in beds in secondary rocks, and principally in that group or series of strata and beds named the coal formation. The principal coal-mines in Scotland and England are situated in the coal formation.

2. Glance-Coal.—Jameson.

Harzlose Steinkohle, *Mohs*; Anthracite, *Hatty*; Glanzkohle, *Werner*.

Specific Character.—Colour black. Imperfect metallic lustre. No bituminous smell. Hardness = 2.0, — 2.5. Sp. gr. = 1.3, — 1.5.

Description.—Colour generally from black. Occurs in fibrous and columnar distinct concretions; massive, vesicular, and disseminated. Lustre ranges from splendid to glimmering, and is imperfect metallic or silky. Fracture conchoidal, uneven, and slaty. Opaque. Some varieties soft. The varieties with splendid lustre and conchoidal fracture are named *conchoidal glance-coal*; those with slaty structure *slaty glance-coal*; the columnar varieties *columnar glance-coal*; and the fibrous and soiling varieties *fibrous glance-coal* or *mineral charcoal*.

Geognostic and Geographic Situations.—Glance-coal, like black-coal, occurs in beds in the coal formation in the secondary class of rocks within the middle division of Scotland, and Kilmarnock, Saltcoats, and Sanguhar, may be mentioned as localities; it also occurs in veins and imbedded masses in secondary trap, as in the Calton-Hill at Edinburgh. It differs from the other kinds of coal, by its occasional appearance in rocks of the primitive formation.

New Minerals.

No descriptions are here given of the minerals enumerated in the following list, because, although the accounts of them given by mineralogists are in general correct, they are not complete, and it would have extended this article much beyond the limits prescribed to it, to have detailed all that has been published in regard to them.

1. Allophane. 2. Bismuthic silver. 3. Blende. 4. Brewsterite. 5. Fluat of Cerium. 6. Comptonite. 7. Conite. 8. Cronstedite. 9. Couzeranite. 10. Giesekite. 11. Gismondite. 12. Heulandite. 13. Hisingerite. 14. Humite. 15. Ligurite. 16. Melilite. 17. Molybdenic silver. 18. Orthite. 19. Polyhallite. 20. Pyralolite. 21. Pyrrhotite. 22. Pyrosomalite. 23. Sapparite. 24. Skorodite. 25. Spinelane. 26. Stalposiderite. 27. Sordawallite. 28. Thomsonite. 29. Wavellite. 30. Yttrochalcite. 31. Zurlite.

Plates.

The figures in the Plates of Mineralogy, from fig. Plates. 27 to fig. 46, refer to the cleavage of minerals.

GEOLOGY.

Geology, as already mentioned, is that branch of history of mineralogy which treats of the atmosphere, the waters of the globe, and of the mountain rocks, of which the earth is composed. The natural history of the atmosphere is given in the article METEOROLOGY, and that of the waters of the globe under various heads in the Encyclopædia, as OCEAN, SPRINGS,

Geognosy. **LAKES, RIVERS, &c.**; and therefore our present business is with the natural history of the solid materials, of which the crust of the earth is composed. This particular department of geology is now generally known under the title **Geognosy**; and may be defined as that branch of mineralogy which makes us acquainted with the physiognomy of the earth's surface, and also with the internal structure, relative position, and mode of formation of the mineral masses of which it is composed.

Geognosy had scarcely an existence before the time of Saussure and Werner. The former of these celebrated philosophers, as Cuvier remarks, "by a laborious investigation of the most inaccessible mountain district, during twenty years of continual research, in which he examined the Alps on all sides, and penetrated through all their defiles, has laid open to our view the entire order of the primitive formations, and has clearly traced the boundaries by which they are distinguishable from the secondary formations. The other equally celebrated geologist, taking advantage of the numerous excavations in the most ancient mining district in the world, has fixed the laws which regulate this succession of strata, pointing out their relative antiquity in regard to each other, and tracing each of them through all its changes and metamorphoses. From him alone we date the commencement of real geognosy, so far as respects the mineral natures of the strata." Cuvier ranks next to the illustrious naturalists just mentioned. His numerous discoveries in the natural history of fossil organic remains; his inquiries into their distributions in the various mineral formations, and his elegant general views, have added much to the natural history of the globe, and contributed in an eminent degree to the advancement of geognosy. Hutton, our distinguished countryman, by the boldness and originality of his speculative views; Whitehurst, by his accurate and interesting descriptions; Playfair, by the publication of his splendid illustrations of the Huttonian theory; Greenough, Buckland, Macculloch, Jameson, and many others, by their investigation of the interesting mountains and plains of Great Britain; and the united efforts of the Wernerian Society of Edinburgh, and of the Geological Societies of London, Cornwall, and Cambridge, have, in a wonderfully short period of time, not only very greatly extended the boundaries of this science, but procured for it a host of active and intelligent cultivators; so that, at present, it is, of all the branches of natural history, that which is the most enthusiastically pursued in this island.

The principal details and theories connected with geognosy having been already given in a previous article, we shall at present confine ourselves to a short description of the physiognomy of the earth's surface; of the changes it has experienced through the agency of the atmosphere, and water; and conclude with a general account of the rocks of which the earth is composed.

Geognosy. **I.—Physiognomy of the earth's surface, or description of the various inequalities observable on the dry land, and on the bottom of the sea.**

On a very general view, the surface of our globe appears arranged into land and water. The water occupies nearly three-fourths of its surface, and the dry land (above its level) is arranged into masses of various forms and magnitudes. This dry land is not equally distributed; for a much larger portion of it occurs to the north than to the south of the equator; and the difference in this respect is so great, that the southern half is principally water, while the northern is chiefly land.

This great accumulation of land in the northern half of the globe suggested to some geographers the idea of the existence of a southern continent, which was necessary to counterbalance the mass of land situated in the northern hemisphere. The discoveries of Cook, however, have shown, that, up to the 70° south latitude, there is no appearance of continent; and that these dreary regions of water and ice are only diversified by a few islands. Beyond this limit, towards the pole, there remains only about five or six hundred thousand square marine leagues, in which there can be any land, inaccessible to navigators, on account of the ice, but the whole of this mass would slightly alter the proportion between the two hemispheres.* But the part of the land above the surface of the sea is so small, in proportion to the whole mass of the globe, that the effect of its unequal distribution upon the equilibrium of the globe is so inconsiderable, as to produce no sensible effect.

The dry land is arranged into two grand divisions, named *Worlds*, viz. the *Old World*, and the *New World*. The *Old World*, in the eastern hemisphere, extends from south-west to north-east, and comprehends the three continents, viz. Africa, Asia, and Europe. The *New World*, in the western hemisphere, extends from north to south, and is composed of two continents, viz. North and South America.

The old and new worlds have the following feature in common—northern and southern halves, connecting isthmuses, a peninsula on the one side, and a group of islands on the other. This arrangement will appear evident from the following details:

The old world may be considered as composed of two great halves, whose greatest direction is from north to south; the one, the western, includes Europe and Africa; the other, the eastern, Asia and New Holland. In the western half, the two parts or continents, viz. Europe and Africa, are connected together by the Isthmus of Suez, and have, on the one hand, the Islands of the Mediterranean, and on the other the Peninsula of Arabia. In the eastern half the two continents of Asia and New Holland are, to a certain extent, connected together by the Islands of Java, Sumatra, &c.; and in front of this broken isthmus is Papua and other islands, and on the opposite side the Peninsula of India. The new

* The lately discovered islands to the south of Cape Horn, named New South Shetland, were at first considered as portions of a *Terra Australis*.

Geognosy. world is composed of two halves, a northern and southern; these are connected together by the Isthmus of Darien, and on the front are situated the West India Islands, and behind the Peninsula of California.

Another general feature in the distribution of the dry land is the tending of all the great peninsulas towards the south. This is the case with Africa, Arabia, India, South America, Scandinavia, Spain, Italy, Greece, Corea, Alashka, Kamschatka, California, Florida, and Greenland.

Besides the old and new worlds, in the sense above described, there occur, dispersed through the ocean, numerous smaller masses of land, forming islands of various magnitudes and forms. Those islands, situated near to the continents, are considered as belonging to them. Thus, the British Isles belong to Europe, those of Japan to Asia, the West India Islands to America, and Madagascar to Africa. But there are other islands situated at a distance from continents, and which cannot be referred to any of the preceding divisions, but to the oceans in which they are situated.

Such are the general distributions of the land above the level of the sea; that below the waters of the ocean, or the *submarine land*, presents considerable variety in form and in distribution, as we shall explain particularly afterwards.

Inequalities of the Surface of the Dry Land.

The surface of the dry land exhibits great variety in aspect, forming mountains, hills, valleys, and plains. The most general divisions of these inequalities, established by geographers, are into *high land* and *low land*; and the more particular into *mountain groups*, *hilly land*, *mountain chains*, *mountains*, *plains*, and *valleys*.

HIGH LAND AND LOW LAND.

The surface of the dry land, on a general view, may be considered as composed of *high land* and *low land*. By the first we understand a lofty, uneven, and widely extended mass of land; by the second, a great and widely extended low and flat country. These high and low lands occur in all the great continents already enumerated. Thus, in Europe there is one extensive low land, bounded by two or three great high lands, which lie to the north and to the south. The southern high land has its central part in the Alps, to the east of Switzerland; towards the west it extends to the Atlantic Ocean, towards the east to the Black Sea. The northern high land comprehends the great range of Britain, that of Sweden and Norway, and some ranges in European Russia, which connect the lofty land of Norway with the Uralian range. It is between these high lands that we find the great European *low land*, which comprehends the northern part of France, the Netherlands, Holland, Lower Germany, Silesia, Poland, and the greater part of European Russia, to the foot of the Uralians.

HIGH LAND.

These high lands are composed of chains of mountains, variously arranged in regard to each other,

Geognosy. and to a central and high chain; and the numerous concavities and hollows between these chains and mountains form the different kinds of valleys. Interposed between these and the low land are ranges of lower hills, forming what is called *hilly land*. In order to obtain a clear notion of the structure of the high land, it will be advantageous to premise a short account of the forms of single mountains, and of chains of mountains.

1. *Single Mountains.*

In single mountains, or hills, we can, in general, distinguish three different parts, named the foot, acclivity, and summit.

Foot.—The foot is the lowest and flattest part. It sometimes extends to a considerable distance, and then rises under an angle of 8° or 10° ; when it is less extensive, or has a smaller base, it rises under a somewhat greater angle, but never greatly exceeds 10° . The mountains in wide valleys have generally a considerable foot, but in those in narrow valleys the foot is less in extent. Sometimes, as in mountains having a *mural* ascent, there is no foot. The inconsiderable inclination of the foot of mountains is owing to the extensive cover of debris, or alluvial soil, spread over them.

Acclivity or Ascent is the space between the foot and summit of a mountain. It is generally the steepest and most considerable part of it. Its inclination is less or more than 30° , and on this depends the greater or less depth of the soil. Upon an acclivity of 30° , and even more, we find a good cover of soil; at 45° , however, the acclivity is too great to admit the growth of trees. Sometimes the acclivity is perpendicular, forming mural precipices; and it is either mural on one, two, or all sides, or in single spots. Granite, porphyry, and sandstone, afford examples of such acclivities. Humboldt remarks, in regard to acclivities in general, that they are to be reckoned considerable when their angle is 7° or 8° , which is the maximum for carriages; that they are very steep when 15° , which is the maximum for loaded beasts of burthen; that an inclination of 35° is so great, that we cannot ascend it without cutting steps in the rocks; and that, even with the aid of steps, an inclination of more than 44° is very difficult of ascent.

Summit is generally the smallest part of a mountain, and is less steep than the acclivity. There occur, however, exceptions to this: thus, there are summits that rise more rapidly than the acclivity; and these are usually very high, almost of equal height with the acclivity, and completely bare. Summits of this description are frequent in Switzerland, where they are named *peaks*. In Switzerland, many of the summits are very narrow, high, and sharp, and are named *needles*. When the peaked or sharp conical form becomes more obtuse, *obtuse conical* summits are formed. When the cones become very flat and roundish they resemble domes, and such summits are said to be *dome-shaped*. Many summits have a convex or obtuse ridge-form, and these are named *round-backed*, and not unfrequently the summit is flat and like a table, when it is said to be *table-shaped*. These various forms of the summit

Geognosy. depend, in some measure, on the nature of the rocks; thus, soft and easily decomposable rocks present a soft outline, while those composed of hard and difficultly decomposable rocks have a very uneven and sharp contour. The position of the strata also materially affects the forms of summits, for it frequently happens, that vertically disposed hard strata form peaks and needle summits, while horizontal strata form tabular summits. The vertical strata of gneiss in some districts in Scotland, afford fine examples of the peaked and denticulated summits, some of the softer granites of Aberdeenshire of the obtuse conical summits, the clay-slate of the outer ranges of certain Highland districts of the round-backed summits, and the hills of the secondary trap formation, and of some sandstones, the table-shaped summit.

II.—Chains of Mountains.

When a greater or lesser number of hills or mountains are connected together in a lengthened form, and in a single series, they are said to form a *chain of mountains*. It seldom happens that single chains of mountains occur in a country, they being generally more or less numerous, and variously aggregated together.

III.—General Description of a Mountain Group, or Alpine Group.

In the higher and more central parts of the high land, many chains of mountains occur together, and in a determinate order, and form what may be denominated a *mountain group*, or *alpine group*, or system or mass of mountains. When a mountain group is viewed as a whole, it appears highest in the middle, and this highest part extends through the whole group, without being in any part of its course intersected. This elevated part we denominate the *high mountain chain*; it is the *faîte* of French geologists; the *juga montium*, *scrre* and *sierra*, of geographers.

The transverse section of a mountain group has, in general, a triangular form, in which the height bears a small proportion to the base. The two sides of the triangle form what are termed the *acclivities* of the group; their intersection at the upper edge, the *high mountain ridge*; the inferior part of each inclined plane, the *foot* or bottom of the group; the two small faces (the ends of the prism), the *extremities* of the group; its *length* is the distance from one extremity to the other; its *breadth* is that across from one foot to the other; and the *height*, the vertical elevation from the high mountain ridge to the level of the sea; and lastly, the point of the compass, towards which the high mountain ridge is directed, is the *direction*. On each of the acclivities there are chains of mountains which shoot from each side of the high mountain chain, in the manner of the ribs from the vertebral column of an animal. Between these chains, which become lower as they approach the foot of the group, are situated those great hollows or concavities named *principal valleys*. Some chains take their rise at the high mountain ridge, and terminate in the principal valley, before they reach the foot of the accli-

Geognosy. vity; others rise in the middle of a principal valley, and terminate at the foot of the group; and this arrangement gives rise to short valleys, having the same direction as the principal valleys, and contained in them. The acclivities of two opposite chains, which form the sides of the same valley, meet together, in a more or less tortuous line, in the bottom of the valley, or in what is termed by continental geographers the *thalweg*. The principal valleys, at their upper extremity or at the point of their origin, terminate in a roundish hollow which cuts the high mountain chain, and which is termed a *gorge* or *pass*. Between any two adjoining gorges, the high mountain ridge retains its primitive height, and forms a protuberance or *summit*; so that a high mountain chain, in its line of direction, appears denticulated or composed of an alternating series of gorges and summits. The gorges or passes are the points of departure of any two valleys on opposite sides of the group; and the summits are the points of departure of any two opposite chains. The principal mountain chains just described are again connected with others which proceed from them in a perpendicular direction; these form what are termed *secondary chains*, and the hollows or valleys between them *secondary valleys*; from these secondary chains others proceed, and give rise to *tertiary chains*, and *tertiary valleys*. Many valleys of a *fourth*, and even of a less considerable magnitude, occur, which do not require any further description.

IV.—Particular Description of a Mountain Group, or Alpine Group.

a. Water-Shed.

The summit of the high mountain chain is, as already mentioned, named the *high mountain ridge*. It is the *water-shed* for the whole group, and is the line formed by the meeting of the two acclivities. French geologists term it *ligne de partage des eaux*; German geologists named it *wasser scheide*; and by geographers it is named *divortia aquarum*. The exact determination of this line is often of great importance; for example, when it is to be taken as the boundary of two neighbouring states, as was the case in the treaty of the Pyrenees (art. 42), where it was stipulated that the water-shed was to serve as the boundary between France and Spain. We must not, however, believe that the water-shed is always the highest part of a mountain group; for, as we shall afterwards explain, some of the subordinate ranges are occasionally considerably higher.

On crossing the high mountain ridge, we often pass immediately from the one acclivity of the group to the other; but in other cases, the high mountain summit is very broad, and when this takes place, we have a distance of several miles, or even leagues, before we cross from one acclivity to the other. Thus in the great alpine country of Norway, named the *Lange Field*, the summit of the high mountain chain varies in breadth from 24 to 36 miles. Mexico also presents a striking example of a summit which has a breadth and a length of many leagues. But even in these summits, or *alpine platforms*, or *table lands*, there is a water-shed; and it is this line which represents in every case, correctly considered, the

Geognosy. geometrical summit of the group. In some mountain groups, as the Grampians and the Pyrenees, the high mountain chain has the same general direction from one extremity to the other; in other cases, there is a change of direction; thus the Alps, after ranging from W. S. W. from St Gothard to beyond Mont Blanc, turn suddenly to the south, and maintain their new direction to the shores of the Mediterranean. During the different changes in the direction of the high mountain chain, it experiences considerable variation in height, becoming very low in some parts of its course.

b. *Acclivities.*

The inclined planes that proceed from each side of the high mountain chain are, as formerly mentioned, named the acclivities of the mountain group. The angle of inclination of the acclivities varies from 2° to 6° ; thus that of the northern acclivity of the Pyrenees is from 3° to 4° ; that of the southern acclivity of the Alps, from the line formed by the colossal summits of Mont Blanc, Mont Ceven, and Mont Rose, and of which the general height is 3500 metres, to the plains of Piedmont and Lombardy, is $3\frac{1}{2}^{\circ}$. But as such a general inclination is made up of many particular inclinations, on account of the irregularities of the acclivity, we must, before we reach the summit, ascend and descend acclivities much more considerable than that we have just mentioned. The two acclivities of a group have seldom the same degree of inclination; on the contrary, the one is generally shorter and steeper than the other. Thus the western acclivity of the Grampian mountain group is steeper and shorter than the eastern; the northern acclivity of the Erzgebirge is long and gentle, while the southern is rapid and short; in the Pyrenees, the northern acclivity is more extensive and steeper than the southern; and the western acclivity of the Andes is shorter and steeper than the eastern. These differences of inclination of the acclivities have long engaged the attention of observers, and they have endeavoured to discover some law to which they may be referred. Bergman, in his *Physical Geography*, maintains, that in chains having a north and south direction, the western acclivity is always the steepest; and that in chains ranging from east to west, the southern acclivity is the steepest. Dr Walker also maintained the same opinion, and used to refer to the phenomena in the Highlands of Scotland for illustrations of its truth. There can be no doubt of this arrangement occurring in some groups, but it is by no means a general one.

Andréossy, the celebrated engineer, remarks, "That when ranges of mountains are situated on the acclivities of a mountain group, such as the Jura, Vosges, Cevennes, situated on the grand acclivity descending from the Alps to the ocean, that the acclivities of the ranges looking toward the upper part of the acclivity of the group are the most abrupt;" he names it *contre-pente*, in opposition to the other acclivity, which being inclined in the direction of the general acclivity of the chain, bears the name simply of *pente* or acclivity. The observations of Saussure accord with this statement, for he says, "The inte-

rior chains turn their back to the exterior parts of the Alps, and present their escarpement to the central chain." It has also been remarked, that the mountains immediately around lakes, as those around the lake of Geneva, have their escarpement, that is, their most abrupt face, toward the lake.

c. *Lateral and Subordinate Chains.*

Those chains, which are situated on the acclivities of the group, present nearly the same phenomena as the high mountain chain. The ridges of these chains, on a general view, diminish in height as they approach their termination; but this is not always the case, because we sometimes find them maintaining their original height for a great length, and sometimes terminating abruptly. These lateral ranges also sometimes rise to a greater height than the high mountain range; thus the highest summits in the Pyrenees are not in the high mountain chain, but at a distance from it: Mont Perdu, the highest summit in the Pyrenees, is not in the high mountain chain, but in one of the lateral chains. These lateral chains have others rising from them under various angles, and thus forming another series of valleys, and these again, in their turn, in a similar way, give rise to still smaller chains and valleys.

d. *Mountain Arm.*

Sometimes a lateral branch or chain passes on from the foot of the acclivity into the bounding low country, and then forms what is called a *mountain arm*; and which, if continued to the sea, and terminates abruptly, forms a *cape* or *promontory*. In other cases, on the contrary, one of the lateral chains does not reach the foot of the mountain group, but terminates at a greater or less distance from it, and thus leaves an empty space between the extremities of two lateral chains, which are to the right and to the left of it. If the sea washes the foot of the mountain group, it invades the space between the two chains, and forms a *gulf*.

e. *Valleys.*

The concavities or hollows in a mountain group are denominated *valleys*. These are of various magnitudes. The principal or largest valleys are those that rise towards the high mountain chain, and which descend from it in a direction nearly perpendicular to its direction, and terminate at the foot of the group. Their general position is across the acclivity; hence they are sometimes named *transverse valleys*. They receive from their right and from their left, and nearly perpendicular to their direction, the valleys of the second order; and these latter valleys receive, in their turn, the valleys of the third order, or the branches of the third order, and so on of the other branches and valleys of smaller dimensions.

f. *Bottom of Valleys.*

As we ascend in valleys towards the chains from which they take their rise, we find that the inclination of the bottom is not every where uniform. The inclination is usually uniform and gentle, until we reach the ramifications at its upper part, when it

Geognosy. increases considerably, and sometimes we cannot reach the mountain chain but by a very steep ascent, sometimes, indeed, nearly vertical, so that the valley seems to terminate suddenly opposite to a perpendicular face. Examples of these appearances on the small scale occur in Glen Cloy, in the Island of Arran, and in Glen Corse, near Edinburgh. Beyond these precipices, in some valleys, in following the course of the water, the valley contracts and again enlarges, and this several times before reaching its termination. Most of the larger valleys present, in their course, a series of contractions and enlargements, thus forming a series of basins ranged in stages, the one above the other, and seldom communicating but by narrow openings. The valleys in the course of the Don, in Aberdeenshire, Beaulieu, in Inverness-shire, Tay, in Perthshire, and Nith, in Dumfriesshire, are of this description. Saussure describes several basins as occurring in the valley of the Rhone; the large and beautiful valley of Aosta, according to Daubuisson, has three basins; and the valley of the Nile, in Upper and Middle Egypt, presents a series of similar basins.

g. Salient and re-entrant Angles of Valleys.

Another curious phenomenon exhibited by valleys is their salient and re-entrant angles. "We see, in the Pyrenees," says Raymond, "some valleys whose salient and re-entrant angles so perfectly correspond, that if the force which separated them were to act in a contrary direction, and bring their sides together again, they would unite so exactly, that even the fissure could not be perceived." This appearance was first particularly noticed in the Alps by Bourguet.

h. General Direction of the great Valleys of a Group.

The direction of the principal valleys of a group, as we have already explained, is nearly perpendicular to the high mountain chain; and it is in consequence of this that valleys of this description, on a general view, and independent of local deviations, are ranged in the line of dip of the greatest acclivity. The Grampians in Scotland, and the Pyrenees in Spain, afford illustrations of this fact. But at the extremities of a high mountain chain, when the ridge becomes low, and does not rise again, the valleys ought to diverge round the point where the sinking begins; they are no longer perpendicular to the high mountain chain, and may become parallel to it. Examples of this arrangement occur in Scotland. Andreossi, speaking of such an appearance, says, "that when valleys are disposed in this manner, the mountain group to which they belong may be considered as terminated."

k. Gorges or Passes.

These are the small valleys or hollows in the high mountain chain. As these are the lowest points on the summit line of a high mountain chain, they will form the lines of communication between two countries separated by a mountain group. Notwithstanding their low situations, in regard to the neighbouring heights, they are nevertheless highly elevated above the level of the sea. The great passes lead-

Geognosy. ing from France into Italy afford striking examples of these short valleys; one of these, the great St Bernard, is 2500 metres above the sea; the little St Bernard, another pass, is 2200 metres above the sea; and a third, Mount Cenis, is 2060 metres above the level of the sea.

l. Forms of Mountain Groups.

The general aspect of a mountain group depends very much on the shape of the summits of the mountains of which its various chains are composed. Each group is in some degree characterized by these: In this view mountain groups are divided into *common*, *conical*, and *alpine*. In the *common mountain group*, the individual mountains of which the chains are composed are joined nearly by the summits. In the *conical mountain group*, the individual mountains of which the chains are composed are also singly aggregated, but not joined higher up than the acclivity; so that they appear conical. In the *alpine mountain group*, the mountain chains are composed, not of single mountains joined together, but of groups of pyramidal-shaped mountains, in which groups a large pyramidal mountain has arranged around it a number of smaller mountains of the same figure.

m. Connections of Mountain Groups.

Mountain groups seldom occur isolated, as is the case with the Grampians and the Pyrenees; more generally several occur together, and when this is the case, we observe that they are connected together or separated from each other in various ways. Sometimes they are separated from each other by seas; it is thus that the extremity of the Alps of Europe, or Mount Hamus, is separated from the Caucasus by the Black Sea. In other cases they are separated by plains, placed between the foot or the extremities of the groups, as is the case with the Alps of the Tyrol, which are separated from the Böhmerwald and other mountains of Bohemia, by the plains of Bavaria. Principal valleys sometimes form the limits between two mountain groups; thus the Cevennes group is separated from the French Alps by the valley of the Rhone. Small groups of hills occasionally form the boundaries: it is thus that the Vosges are separated from the Jura group, and the Pyrenees from the Cevennes. Lastly, mountain groups are separated by natural sections; in this way the Jura group is separated from the French Alps by the deep and narrow ravine near the Fort of Ecluse.

n. Series of Mountain Groups.

Mountain groups, in regard to their connection, are either *isolated*, or several are joined together, forming a *chain* of mountain groups. A chain of mountain groups extends from the Alps of Switzerland to Servia and Bulgaria; a similar range is formed by the Fichtelgebirge, which is connected with the Carpathians by the mountain groups of the Erzgebirge, Riesengebirge, Silesian, and Moravian groups.

o. Direction of Mountain Groups.

The direction of mountain groups, and of chains

Geognosy. of mountain groups, is the same as that of the greatest dimension of the continent or island in which they occur. Thus, in Scotland, the high land, extending from Dumbarton to Cape Wrath, is in the direction of its greatest dimensions, which is from N. to S.; in the mainland of Shetland, the principal group is also in the direction of its greatest length; and in Norway, the great high land ranges from north to south, in the direction of its greatest length.

p. Basins and Lakes in Mountain Groups.

Numerous basins or concavities among mountains are filled with water, forming lakes, while others are without water, or empty. These lakes are met with principally at the foot of mountain groups, or near to their high mountain chain,—that is, at the upper extremity of the principal valleys, very near the gorges or passes. There are lakes at the highest points of the three grand passes from France into Italy by Mount Cenis, the little St Bernard, and the great St Bernard; the first is half a league in length, and the latter has a contour of three or four miles. In the valleys in the interior of mountain groups many basins occur, placed in succession above each other; and the same disposition is seen in the great valleys of rivers, far from the centre of mountain masses.

V. Hilly Land

Is composed of ranges of hills, which are irregularly grouped together, and whose elevation, in general, does not exceed 1000 feet. There is no central, or high mountain chain towards which the others tend. It forms the link which connects the mountain group with the low land, and often there is a gradual lowering of the hills until they are lost in the plains.

LOW LAND.

The low land is formed principally of large and extensive plains, little elevated above the level of the sea, on which we occasionally observe gentle risings and undulations of the surface, that often extend to a considerable distance, and sometimes form the limits between neighbouring rivers.

The plains of the low land are characterized by the presence of particular hollows, or concavities, which are denominated *river-valleys*, or *river-courses*. In these, there are to be distinguished the *bed* of the river, and the *holn*, or *haugh* land: Further, there are to be observed the *high* and *low* bank of the river, and the ravines, or small valleys, that traverse the high bank and terminate in the low bank. There is still another kind of hollow met with in low land; it is that formed by shallow and wide extended lakes. Numerous instances of this appearance occur in the great European low land.

Before proceeding to describe the forms of the submarine land, we shall give descriptions of *coasts* and *caves*.

Coasts.

The edge of the dry land, where it meets the waters of the ocean, has received the general name of coast. It varies in its aspect. Sometimes it is formed of steep and rugged rocks, which are either low,

or rise to considerable height; in other cases, it is composed of shelving irregular rocks; on the coast of Holland, and in other countries, it is formed of low sandy hills termed *dunes*; and lastly, in the tropical seas it is more or less deeply incased with corals of various descriptions, forming what are called *coral-reefs*.

Caves.

These are cavities of greater or less extent, which are either open to day, or are more or less completely concealed in the interior of the earth. They are divided into *external* and *internal* caves.

1. *External Caves*.—These are great hollows open to day, and which occur in the faces of cliffs on the sides of valleys, and in steep cliffs and precipices near the coast, or which hang over the sea. Limestone and sandstone cliffs and precipices often exhibit caves of this description, and similar caves, sometimes of great magnitude, occur in primitive and transition rocks. The great open caves on the west coast of the Island of Arran are situated in sandstone, and the same is the case with those on the coast of Fife-shire and Angus-shire; the striking cave of Smoo, in Sutherland, is in limestone, and those of the Islands of Isla and Jura are in primitive rocks.

2. *Internal Caves*.—These are situated either in the centre of mountains, and without any direct communication with the atmosphere, or they are situated in the interior of rocks, but communicate with the external air by means of passages of greater or less extent. Completely included caves, and sometimes of great extent, occur in limestone, gypsum, and porphyry rocks, and others communicating by means of passages with the external air in granite, trap, and limestone rocks. The grotto of Antiparos, the caves of Derbyshire, those in several of the Hebrides, as Maclean's Cave, in the Island of Egg, &c. and some caves in the south coast of Fife-shire, are of this description.

SUBMARINE LAND.

The bottom of the sea, like the surface of the dry land, exhibits considerable variety of aspect. In some seas there occur flats and plains ranging to a considerable extent, and near to the surface of the water, forming what are named *shoals*; in other cases, plains of great extent occur deeply seated, or far under the surface of the ocean, and are denominated *deep submarine plains*. These submarine plains, like the plains on the dry land, sometimes contain hollows of considerable extent, and of great depth, which have not received any particular name. Mr Stevenson's interesting map of the German Ocean, in the third volume of the *Memoirs of the Wernerian Natural History Society*, presents an accurate view of the submarine plains and hollows of that part of the ocean. These submarine plains are often varied by the appearance of hilly ranges corresponding with those on the dry land.

In the tropical seas, by the accumulation of corals, numerous inequalities are formed in the submarine lands. The coral surface is always very rough and sharp, and when near the surface of the water, forms *coral-reefs* and *coral-shoals*. Sometimes the

Geognosy. inequalities are so considerable, as to form ranges of submarine coral-hills, or the rough, sharp, and rugged surface extends to a vast distance in the form of coral-plains.

II. CHANGES INDUCED ON THE SURFACE OF THE EARTH BY THE DESTROYING AND FORMING EFFECTS OF WATER AND THE ATMOSPHERE.

Having now enumerated and described the various inequalities observable on the surface of the dry land and the submarine land, we shall next give an account of the changes they have undergone by the agency of the waters of the globe and the atmosphere.

Action of Water.

Water, Werner remarks, acts mechanically, when it removes part of the soil over which it passes or corrodes the channel in which it flows, or the reservoirs in which it is contained; it also acts mechanically, when, on being imbibed by rocks, it increases their weight, and thus favours their rending, slipping, and overturning; and lastly, it acts mechanically, when, by its freezing in fissures, it breaks up mountain masses and rocks.

It acts chemically when it dissolves particular mineral substances out of the rocks through which it percolates.

DESTROYING EFFECTS OF WATER.

I. *Mechanical Destroying Effects of Water.*

1. *Rain water*, when it first touches the surface of the earth, simply moistens it: on sinking deeper, it supplies springs; and if the fall is violent, as is the case in thunder-storms and water-spouts, much of the soil is carried away, and considerable tracts are in this way bared to the naked rock. The rain water, in its progress towards the lower parts of the earth, flows either into ravines, and from these into valleys and beds of rivers; or when it meets with no furrow or ravine, scoops out a bed for itself. Torrents, when they descend from the sides of mountains, and even where the declivity of their course is not very great, produce effects which nothing but direct experience could render credible. "The fragments of rock," Professor Playfair remarks, "which oppose the torrent, are rendered specifically lighter by the fluid in which they are immersed, and lose by that means, at least, a third part of their weight; they are, at the same time, impelled by a force proportional to the square of the velocity with which the water rushes against them, and proportional also to the quantity of gravel and stones which it has already put in motion. Perhaps, after taking all the circumstances into computation, in the midst of a scene perfectly quiet and undisturbed, a philosopher might remain in doubt as to the power of torrents to move the enormous bodies of rock which are seen in the bottom of the narrow valleys or deep glens of a mountainous country; but his incredulity, says an experienced traveller, will cease altogether, if he has been surprised by a storm in the midst of some alpine region; if he has seen the number and impetuosity of the cataracts which rushed down the sides of the mountains,

and beheld the ruin which accompanied them; and if, when the tempest was passed, he has viewed those meadows, which a few hours before were covered with verdure, now buried under heaps of stones, or overwhelmed by masses of liquid mud, and the sides of the mountains cut by deep ravines, where the tract of the smallest rivulet was not to be discovered."

2. *Rivers.*—These occasion considerable changes in their passage from the mountains to the low country, by corroding the sides of their beds, and by breaking down their banks; and this mechanical agency is much increased when they carry along with them gravel and rolled stones. It is towards the upper part of the channels of rivers that we observe with the greatest distinctness their mechanical destroying effects on the *solid strata*. Professor Playfair remarks, that it is not in the greatest rivers that the power to change and wear the surface of the land is most clearly seen. It is at the heads of rivers, and in the feeders of the largest streams, when they descend over the most rapid slope, and are most subject to irregular or temporary increase and diminution, that the causes which tend to preserve, and those that tend to change the form of the earth's surface, are farthest from balancing one another; and where, after every season, almost after every flood, we perceive some change produced for which no compensation can be made, and something removed which is never to be replaced. When we trace up rivers and their branches towards their source, we come at last to rivulets, that run only in time of rain, and that run dry at other seasons. The changes of the valley of the main river are but slow; the plain indeed is wasted in one place, but is repaired in another, and we do not perceive the place from whence the repairing matter has proceeded. That which the spectator sees here does not therefore immediately suggest to him what has been the state of things before the valley was formed. But it is otherwise in the valley of the rivulet; no person can examine it without seeing that the rivulet carries away matter which cannot be repaired, except by wearing away some part of the surface of the place upon which the rain that forms the stream is gathered. The remains of a former state are here visible; and we can, without any long chain of reasoning, compare what has been with what is at this present moment. It requires but little study to replace the parts removed, and to see nature at work, resolving the most hard and solid masses, by the continued influences of the sun and atmosphere. We see the beginning of that long journey by which heavy bodies travel from the summit of the land to the bottom of the sea. In the lower and flatter districts where the strata are soft and yielding, the mechanical destroying effects of the water of rivers are often on an extensive scale. It is particularly striking when rivers pass through alluvial depositions, when they show by the successive banks and terraces on their sides the great depth to which they have worked. The alluvial matter, thus removed by the river, appears in many cases to have been deposited from the waters of lakes and the rivers con-

Geognosy.

Geognoy. nected with them. The courses of many rivers, as Professor Playfair observes, retain marks that they once constituted a series of lakes, which have been converted into dry ground, by the twofold operation of filling up the bottoms, and deepening the outlets. This happens especially when successive terraces of gravelly and flat land are found on the banks of a river. Such platforms, or *haughs*, as they are called in this country, are always proofs of the waste and destruction produced by the river, and of the different levels on which it has run; but they sometimes lead us farther, and make it certain that the great mass of gravel which forms the successive terraces on each side of the river was deposited in the basin of a lake. If, from the level of the highest terrace, down to the present level of the river, all is alluvial, and formed of sand and gravel, it is then evident that the space as low as the river now runs must have been once occupied by water; at the same time, it is clear, that water must have stood or flowed as high at least as the uppermost surface of the meadow. It is impossible to reconcile these two facts, which are both undeniable, but by supposing a lake, or body of stagnant water, to have here occupied a great hollow, and that this hollow, in the course of ages, has been filled up by the gravel and alluvial earth brought down by the river, which is now cutting its channel through materials of its own depositing. It is said above, that the water must have run or stood, in former times, as low as the present bottom of the river; but there is often clear evidence that it has run or stood much lower, because the alluvial land reaches far below the present level of the river. In the course of the Tay, the Esks, the Annan, Nith, Clyde, and other rivers in Scotland, the phenomena just detailed are beautifully displayed.

3. *Lakes.*—In those lakes having an outlet, the water exercises a destroying effect on the interposing barrier, and next on the channel by which the water flows out, cutting it deeper and deeper until the lake is emptied. Hence the numerous basins observed in mountain countries, which still present, and well preserved, the fissure or channel through which the waters that formerly filled them made their escape. The well-known pass of the Elbe, leading from Bohemia, and that of L'Ecluse, are evidently the fissures or channels through which the waters of formerly existing lakes made them escape; and the *Irongate*, the famous pass through which the Danube flows from the Bannat into the plains of Wallachia, is of the same description. Thessaly appears formerly to have been in the state of a lake; but, as reported, a rent having taken place on one side of it, the water escaped with tremendous violence, devastated the lower country, and covered it with debris. The Waller Lake in the Tyrol rose so much, owing to the melting of the ice of the neighbouring glaciers, that it broke through its natural barrier; its water was precipitated with so much velocity and violence into the lower country, that whole valleys and plains were desolated and covered with rolled masses, and gravel and mud. A few years ago, a lake, of considerable extent, burst

Geognoy. at the top of the valley of Bagne in Switzerland, devastated the whole valley, deposited in its course vast quantities of debris, and carried to considerable distances masses of granite, some of them more than 10,000 cubic feet in magnitude.

Many nearly inclosed valleys or basins are to be traced in the course of the rivers of this and other countries, and all of them have been formerly in the state of lakes, or are so at present. Thus the river district of the Rhine forms many basins, of considerable magnitude, of this description, in its course towards the ocean. The basin in which the Lake of Constance is situated is one of these; a second occurs in Baden, which extends from Upper Alsace to Handruck, and the vicinity of Mayence, where the Rhine forces its way through a narrow rocky passage. The river district of the Danube forms a basin in Bavaria, through which the river flows until near to Passau, when it escapes from it by a narrow pass which leads into a second basin, which comprehends the Austrian hereditary dominions. This basin extends to Presburg, when it terminates, and the Danube again forces its way through a rocky pass into Hungary: This kingdom is a great circular valley or basin, and the Danube, after traversing it, escapes by a rocky pass into the valley of the Bannat. This inclosed valley or basin is smaller than Hungary, and opens on its lower side, and affords a passage to the river through a rocky pass into the plains of Moldavia and Wallachia, which extend from thence to the Black Sea. We have a continuation of these valleys or basins, although still filled with water, in the Black Sea, the Sea of Marmora, and the Mediterranean Sea. The great lakes in North America are also a series of basins, traversed by the river St Lawrence. The Elbe, in its course from its origin in the Riesengebirge, downwards to Meissen, in Saxony, passes from one basin to another, and exhibits such phenomena, as show the great mechanical destroying effects of its waters, and that formerly these basins were in the state of lakes. The river Don, in Aberdeenshire, the Nith, in Dumfriesshire, the Beaul, in Ross-shire, afford other examples of rivers flowing through basins that appear formerly to have been filled with water.

Sometimes the waters of lakes, in place of attacking their barriers on the upper part, pierce them below, and this effect is assisted by the presence of a rent, or fissure, which affords an opportunity for the formation of an aperture. Some of the natural bridges described by authors appear to have originated in this way.

The rending of strata by earthquakes may have afforded openings to lakes, and these bursting out thus suddenly, may have given rise to devastating, and often extensive deluges.

The numerous loose blocks of mountain rocks met with in various countries, at a great distance from any fixed masses, or strata of the same description, appear to owe their present situations to great floods of water. Masses of this kind occur in Scotland, England, Wales, Ireland, Germany, in the great valley of the Po, and in the country between the Alps and the Jura range of mountains. The

Geognosy. magnitude of these masses, which are sometimes 50,000 cubic feet in content, have engaged the particular attention both of the scientific and the curious.

The most detailed accounts of these blocks are those given by Swiss observers, and to these we shall now principally confine our attention, as they are illustrative of their distribution in other countries.

Loose blocks of alpine rocks are found in the lower part of the alpine valleys, which terminate in the great principal valley that stretches between the Alps and the Jura, from the Lake of Geneva to the Lake Constance; and are also found almost every where in this great principal valley. They are sometimes met with 4000 feet above the level of the sea, on the side of the Jura facing the Alps, and also in considerable numbers in many of the valleys of the Jura itself. These blocks occur only on the surface, never in any solid rock, and no one ever met with them in the subjacent strata of sandstone, marl, or conglomerate of the hills and valleys interposed between the Alps and the Jura; but they are sometimes found deep in the soil, or imbedded, or surrounded with the debris formed by rivers.

The traveller is often surprised by the enormous magnitudes of these loose blocks, some of them being calculated to contain 50,000 cubic feet. The smaller masses are distinguished from those brought down by rivers by their position, that is, their occurring on heights and acclivities where no river could ever have run. They may also be confounded with blocks from decaying conglomerate, hence it is proper to be on our guard, not only to distinguish these blocks from those derived from conglomerate rocks, but also from the rolled masses belonging to river courses.

The height at which they are found does not appear to have any relation to their magnitude, for we often find very large blocks at considerable heights, and also in deep valleys; and we also meet with small masses as well in the bottoms of valleys, as high up on the mountains.

They occur sometimes in heaps or dispersed in single blocks; but these relations have no connection with their magnitude, because we often find large and small masses in the same heap, and single, large, and small blocks on mountain summits, and in the bottoms of valleys. The smaller blocks are more or less rounded, but seldom so much so as the boulders of rivers which have been exposed to long continued friction. The larger blocks are indeed angular, but not sharp-edged. But in examining this relation, we must carefully distinguish whether or not the angles or edges are original, or have been produced by subsequent natural or artificial causes. Very often masses of this description are blasted with gunpowder, either with the view of clearing the fields, or of obtaining stones for building; and these, if left on the ground, may lead into error.

These blocks vary in their nature, some being of the primitive class, while others belong to those of the transition and secondary classes. In general, they appertain to rock formations situated nearer to the central alpine chains than those of the places where they are found. Thus no rocks of the transition class occur in gneiss valleys; no alpine lime-

stone in transition valleys; and in general, no where but in the Jura do blocks of Jura limestone make their appearance. Therefore all the loose blocks of rocks between the Jura and the Alps belong to the strata of the high chains of the Alps.

But these blocks have different characters in different districts. The loose blocks which occur in the river basin of the Rhone, and the Lake of Geneva, are quite different from those which lie strewn about in the river basin of the Rhine. These again are equally different from the loose blocks of the river basin of the Aare, as those of the Aare are from the blocks of the Lake of Zurich and the valley of Limmat; and these in their turn are equally well distinguished from the great accumulations in the valley of the Reuss. It rarely happens that intermixtures take place among these different accumulations of debris, and this is a circumstance which must be attended to in our investigation.

It results from an accurate comparison of these loose blocks with those mountain rocks which occur in extensive chains in the high Alps, that the loose blocks of every known river basin agree with the rocks which form the sides of the upper parts of those high alpine valleys which are in immediate connection with these great water basins. Thus the loose blocks of the water basin of the Rhine are similar to the rocks of Bundten. We find in the Lake of Zurich, and in the Limmat valley, the rocks of the Glarner land in loose blocks. The debris in the basin of the Reuss consists of rocks of the mountains from which the Reuss takes its rise. The loose blocks of the water basin of the Aare are similar to the mountain rocks of the high Alps of Bern; and the loose blocks, found in the course of the Rhone, occur in fixed rocks in the Vallais.

It thus appears that the loose blocks are by no means irregularly dispersed over the great valley between the Alps and the Jura, but are distributed in the direction of distinct water basins. It also appears, that the loose blocks are not irregularly distributed in these different basins; on the contrary, that in some parts of the basin they are accumulated in great numbers; in other places they are rare, and in some situations none occur.

From the preceding observations, we may obtain some hints of importance in respect to the cause of this remarkable phenomenon. These loose blocks already occur in the alpine valleys, which open into the great valley, between the Alps and the Jura. They are found more abundantly in the wide parts of valleys immediately below the narrow or contracted passes, and few occur in the narrow steep and rocky parts of the valleys.

Loose blocks are found, at a greater or less height, in the smaller lateral valleys that open into the transverse alpine valleys, which terminate in the great valley between the Alps and the Jura. If these lateral valleys form passes (which lead over into other valleys by a lowering of the high mountain chain) which are not more than 4000 feet above the level of the sea, loose blocks occur, not only in these passes, but also more or less widely distributed in the opposite valleys. In the great principal valley which stretches between the Alps and the Jura, from

Geognosy.

Geognosy. the Lake of Geneva to beyond the Lake Constance, we find these loose blocks dispersed over all the hills whose elevation is not more than 3000 feet above the level of the sea; but even here, the distribution of the blocks is not entirely irregular. The largest are found on such hills and acclivities as are opposite the mouths of the alpine valleys, in the great principal valley. The blocks are frequently found higher on such acclivities than on the sides of those valleys which may be considered as a continuation of the alpine valleys. The loose blocks are found every where on that acclivity of the Jura range which is opposite to the Alps, and they are found highest and largest in those places which are directly opposite the mouths of the alpine valleys. In such places, the blocks again attain an elevation of nearly 4000 feet above the level of the sea; whereas in the intermediate places, which are most remote from the places opposite the mouths of the alpine valleys, the blocks seldom reach at a height of 2000 feet above the level of the sea.

In those places where the Jura chain branches into the great valley between the Jura and the Alps, loose blocks are found in the valleys behind the projecting chains. The Jura range is sometimes intersected in places opposite to the Alps; and it is remarked, that loose blocks are met with in the valleys behind these intersected portions of the range; and that, when loose blocks occur in the Jura range at a distance from the Alps, it is only in such places as are directly opposite to the intersected portions of the chain opposite to the Alps.

The circumstance of the non-occurrence of these blocks in the sandstone, marl, and nagelfluh, which occupies the great valley between the Alps and the Jura, proves that that revolution of our globe by which these were dispersed, took place after the formation of these rocks, and may therefore have belonged to one of the latest changes which have contributed to the present form of the earth's surface.

When we compare the relations of the alluvium of the rivers in valleys with those of the loose blocks, their similarity must strike every one. Thus, rolled masses are seldom deposited in those places where a river forces its way through a narrow passage; but where an expansion takes place, owing to the distance of the banks increasing, the rolled masses are sometimes accumulated in whole banks. In the same manner loose blocks seldom occur in the narrow passages of the transverse valleys in the Alps; but as soon as widenings of the valleys take place below these narrowings, the blocks occur in abundance.

If, during a flood, a rupture takes place in the banks of a river, where it is contracted, a part of the stream will flow out by the lateral opening, and carry along with it rolled masses, even when the opening in the bank does not reach to the bottom of the bed of the river; for the mountain stream, loaded with boulders, carries them not merely in single masses along its bottom, but the flood water of the stream generally attacks large sand-banks, or older beds of rolled masses, and carries along with it, accompanied with a terrible noise, whole masses, forces them over the lower banks, or through the chasm in the bank, and often deposits them several feet high on

an immediately succeeding widening of the river's *Geognosy.* course.

In the same manner, we observe loose blocks deposited on high situations in the lateral valleys of the great transverse valleys, and dispersed over the passes into the neighbouring valleys. The height of the lateral deposits of loose blocks, and their position in the passes and their passing into neighbouring valleys, are facts which assist us in judging of the extent of the power that may have acted during their transportation.

The striking agreement observable in the phenomena of the distribution of the loose blocks from the interior alpine valleys to the interior valleys of the Jura, with those in the rolled masses carried along by rivers, must lead every one, who reflects on this interesting phenomenon, to the hypothesis, that these blocks may have been deposited in their present situations by an immense flood which burst from the Alps. It is true, that this opinion is liable to many objections; but still it contains a more plausible explanation of the phenomenon than any other with which we are acquainted.

The loose blocks in the different river districts being in general separated from each other, or if any intermixture takes place of the rolled masses of one valley with that of another, it being only on their edges, it is highly probable that the floods which burst from these valleys, and carried along with them the masses of rocks, may have been simultaneous, by which the flood of the one basin would bound and limit that of the other, and thus prevent the water flood of one basin flowing into the neighbouring ones.

The contemporaneous occurrence of these different floods from the alpine valleys, can alone in this hypothesis explain why this aqueous flood was so generally and so highly accumulated in the great valley between the Alps and the Jura, as to reach the height of most of the sandstone mountains, and to a great elevation on the Jura, where many blocks are found deposited. But if the contemporaneous occurrence of these floods is proved by the facts, already enumerated, to what cause are we to refer this simultaneous bursting of floods of water from so many alpine valleys?

We observe, on the north-western side of the chain of the Alps, numerous openings, which, by their structure, seem to point out the action of violent floods. Let us suppose the numerous valleys, in the districts already described, closed at their present entrances, or openings, as would seem from their structure to have been formerly the case; the consequence of this arrangement would be the filling of the alpine valleys with water to the height of the lowest passes among the mountains, and thus an enormous accumulation of water would take place. This great body of water, if let loose at once, by the bursting of the lower extremities of the valleys, would form a flood which would sweep across the sandstone mountains between the Alps and the Jura range, and even ascend high on the Jura itself. This flood of water, moving probably at the rate of 200 feet in a second, and loaded with debris of rocks, would carry masses, even those having a magnitude of 50,000 cubical feet, some thousand feet high on

Geognosy. the Jura range.* But to what cause are we to attribute this effect? This is a question we cannot answer.

4. *Ocean*.—The waters of the ocean exercise a powerful destroying effect on the borders of the basins in which they are contained. If the coasts are bold and rugged, they are violently assaulted by the waves of the ocean; the crags and cliffs split and tumble down in frightful and irregular succession, and if the sea is not too deep in proportion to the mass of land, the debris accumulates at their feet, and in a longer or shorter period of time, a bank of these fragments rises at the foot of the cliff, reaches the surface of the water, even rises above it, and thus a barrier is formed which protects the cliffs from the future assaults of the ocean. If the coasts surround an island whose bulk is inconsiderable in comparison of the depth of the surrounding sea, the whole in the course of time is broken down and buried under the waves of the ocean, and in the place of an island there is formed a rocky shoal.

The perforated rock, the *Dorholm*, on the west coast of Shetland; the perforated rocks described by Captain Cook, near New Zealand; the stalks, holms, and skerries, on the coasts of Shetland, Scotland, Norway, &c. are effects of the destroying power of the waves.

In those rocky coasts where the strata are of unequal hardness, the softer portions, and also part of the surrounding harder mass, are removed by the action of the waves, and thus form the caves so frequently met with on sea coasts. These caves often occur at a considerable distance from the present margin of the basin of the ocean, owing to the interposition of a greater or less extent of newly formed alluvial land. Caves also occur situated in sea cliffs at a considerable height above the level of the sea. Some of these have been formed in the following manner. The cliffs, when their bases were washed by the sea, appear to have been perforated to a considerable depth and height by the impulse of the waves; and large masses of the softer interior strata washed out, and thus internal caves have been formed, situated often several fathoms above the level of the sea. The destroying effects of the sea continuing, the cliffs concealing these internal caves yield, the

Geognosy. internal caves become open caves, and appear at a considerable height above the level of the sea. This mode of formation is well seen in the sandstone cliffs on the east coast of Scotland.

The waters of the ocean often occasion dreadful ravages in the low countries exposed to its fury. Holland furnishes many striking examples of its devastating power. In the year 1225, the waters of the ocean, agitated by a violent tempest, inundated the country; the Rhine, swollen, at the same time, by extraordinary rains, and retained at a great height, partly by the waters of the ocean, partly by the winds blowing in a contrary direction to its course, spread over the neighbouring country; but the tempest having suddenly subsided, the highly elevated waters retired with such velocity and force as to carry with them a considerable portion of the soil, and left in its place the sea now named the *Zuyder Zee*. In the year 1421, a great inundation submerged the southern part of the province of Holland, drowned 60,000 persons, and on retiring it formed, near to Dortrecht, the arm of the sea named the *Bies-Boos*. Florus speaks of a rising of the waters of the sea in the year of Rome 644, which forced the Teutonians, Cimbrians, and Tigurians, back from the countries they inhabited. This was occasioned by a violent north wind, which raised the water of the ocean along the coasts of the countries occupied by these nations.

Such are the general destroying effects of the water of the ocean on the margin of its basin. Let us next inquire what are the changes which it produces on the submarine land.

The motions of the sea, even during a storm, do not reach to a great depth, seldom many fathoms, and hence its destroying effects cannot, in such cases, reach far, although they are sometimes so considerable as to break rocks in pieces, and throw them upon the coasts in masses of various sizes and forms.† But the effects appear to be more considerable in the course of those great currents that traverse the ocean; such as the equinoctial current and the Gulf Stream. The great depth of water in the course of the Gulf Stream would seem to prove that the corroding influence of the water

* The velocity of the burst of water from the Glacier Lake, at the top of the valley of Bagné, and its density owing to the great intermixture of debris, is in harmony with the fact, that it moved along blocks of granite some thousand cubic feet in magnitude, and deposited some of them on the sides of the valleys at a considerable height above their bottoms.

† "In disposing of the waste of the surrounding land beyond the accumulation of the sunken banks of the German Ocean, we are not left at any loss for a disturbing cause, as this is provided by the tides and currents of the sea; and with regard to their action, we have many proofs, even at very considerable depths, by the breaking up of the wrecks of ships, the occasional drift of sea-weed, and also drift timber, into regions far distant from those in which they are spontaneously produced. The dispersion of fishes, convinced by their disappearance from the fishing grounds in stormy weather, tends to show the disturbance of the waters of the ocean to the depth of 30 or 40 fathoms. This observation I have frequently had an opportunity of making near to the entrance of the Frith or Forth. Numerous proofs of the sea being disturbed to a considerable depth have also occurred since the erection of the Bell Rock Light-house, situate upon a sunken rock in the sea, twelve miles off Arbroath in Forfarshire. Some drift-stones of large dimensions, measuring upwards of thirty cubic feet, or more than two tons weight, have, during storms, been often thrown upon the rock from the deep water. These large boulder-stones are so familiar to the light-keepers at this station, as to be by them termed *travellers*."—Stevenson in *Memoirs of the Wernerian Nat. Hist. Society*, Vol. III.

Geognoey. had been sufficient to scoop out a channel or hollow in the bottom of the sea in the line of direction of the current. When the currents of the ocean are assisted by the waves and the winds, destroying effects of great magnitude are produced. It is probably in this way that some straits have been formed. Buffon remarks on this subject, that most of those in the equatorial seas are directed from east to west, like the great equinoctial current, and that it is probable this current may have formed many of them.

5. *Action of Water by its own Weight.*—Water, by its own weight, contributes very much to the degradation of the surface of the globe. Sometimes large masses of rock, particularly those of a soft nature, imbibe much water, by which their weight is increased, and thus occasions breaking, and rending, and slipping of masses often of enormous magnitude. These effects, it is remarked by Bergman, take place most frequently, and to greater extent, during wet than in dry seasons. In proof of this, it may be mentioned, that in the year 1805, at the close of a wet summer, and during a very rainy day, a vast mass loosened from the Rigi-berg in Switzerland. This hill, situated about 1150 metres above the valley in which it occurs, is formed of sandstone, and of a conglomerated rock named Nagelfluh, having a marly basis. On the 2d of September there loosened from it an enormous mass, 4000 metres long, 400 metres broad, and 30 metres thick; it buried in its ruins several villages, destroyed 500 persons, and raised in the bottom of the valley hills nearly 200 feet in height. In the year 1618, the once considerable town of Plurs, in Graubunden, with the neighbouring village of Schelano, were overwhelmed by a vast mass of rock, which had imbibed much water, and separated from the south side of the mountain of Corto. In the year 1714, the west side of the Diableret, in the Vallais, separated, and in its course downwards covered the neighbouring country with its ruins for two miles in length and breadth, and the immense blocks of stones and heaps of *debris* interrupted the course of the rivers; and lakes were thus formed. Many instances are on record of the lakes formed in this way, and of great extent, afterwards bursting, and devastating immense tracks of country.

6. *Effects of the Freezing of Water.*—In the temperate and colder regions of the earth the expansive power of frost in breaking up rocks is often extremely striking. In the history of Norway, and in the descriptions of northern, particularly of arctic countries, we meet with many accounts of the noises and rendings of the rocks by frost. Terrible disasters take place in alpine countries by the bursting and fall of vast masses of rock, split by the freezing of the water in their rents and fissures. Saussure, during the few days of July he passed on the Col de Geant, says, not an hour passed in which he did not hear the noise of rocks splitting and falling down the acclivities by the freezing of the water in their fissures.

7. *Destroying Effects of Ice and Snow.*—Water in the form of ice occasions considerable changes on the surface of the earth. Thus, when floated along in great masses by rivers, it breaks up their

banks, and thus allows them to devastate the lower country; and often the masses are so large, and the power of the river so great, that enormous fragments of the solid strata are thereby torn off and carried to a distance. When sea ice is forced against the cliffs and precipices of the coast, the breaking and destruction it occasions are sometimes almost incredible. For the breaking up and moving of large masses of rock, one of the most powerful engines employed by nature are the glaciers, those great accumulations of congealed water and snow which form the lower boundary of the snow line in Switzerland and other regions of the globe. These great masses, says Professor Playfair, are in perpetual motion, undermined by the influx of heat from the earth, and impelled down the acclivities on which they rest by their own enormous weight, together with that of the innumerable fragments of rock with which they are loaded. These fragments they gradually transport to their utmost boundaries, where a formidable wall ascertains their magnitude, and attests the force of the great engine by which it was erected. The immense quantity and size of the rocks thus transported have been remarked with astonishment by every observer, and explain sufficiently how fragments of rock may be put in motion, even where there is but little declivity, and where the actual surface of the ground is considerably uneven. The fall of consolidated snow often also occasions considerable changes. In mountainous countries vast masses separate, are precipitated with great velocity, accompanied with terrible noises, carrying along with them rocks of vast size, and sometimes burying villages under them.

11.—*Chemical Destroying Effects of Water.*

Rain water enters the fissures of the earth in a comparatively pure state, but often issues forth again more or less impregnated with various mineral substances which it has dissolved or abraded from the strata through which it has passed. Thus, when it passes through beds of rock salt, or of rocks richly impregnated with salt, salt springs are formed, and in this way enormous quantities of salt are annually brought from the interior of the earth. The quantity of salt dissolved is sometimes so great, that internal caves or hollows are formed, whose roofs sometimes fall in, and cause great irregularities on the surface of the ground. Spring water, in passing through beds and masses of gypsum, dissolves a portion of it, and in this way sometimes occasions considerable changes in the interior of the earth. Carbonat of lime also yields to the solvent powers of water, particularly when assisted by carbonic acid. Many of the excavations in limestone hills are partly owing to this destroying effect of water. Other chemical destroying effects of a similar nature might be mentioned, but those we have just stated are the most considerable, and therefore no further detail is here necessary.

DESTROYING EFFECTS OF THE ATMOSPHERE.

The combined influence of the air and moisture of the atmosphere effects great changes on the rocks at the surface of the earth. It either simply disintegrates the rock, or not only breaks it down, but also occasions a change in its chemical constitution.

Geognosy. Sandstone, and other rocks of the same general description, often yield very readily to the influence of the weather; their basis or ground is washed away, and the quartz and other particles remain in the form of sand and gravel. When trap veins intersect strata, it not unoften happens that their outgoing or crop appears rising several feet or yards above the neighbouring strata, and crossing the country like great walls; hence, in Scotland, they are named *dikes*. In other cases, the outgoing of beds of rocks, as of trap, appear rising to a considerable height above the general surface. In these cases, the softer bounding strata have yielded to the gnawing influence of the weather, while the harder trap, and other rocks, more obdurate, and less liable to decomposition, has resisted longer its destroying powers. Numerous examples of these effects occur in Scotland, as in Arran, Jura, Mull, west coast of Argyle, Eigg, Rume, Skye, &c. Veins of quartz also traversing granite, gneiss, mica-slate, and clay-slate, sometimes rise above the surface, and appear as *dikes*.

The various mountain summits owe much of their form to the destroying influence of the atmosphere. The needles, and peaks, and pyramidal forms of Alpine regions, and the tabular and round-backed forms of lower mountains, although not entirely the effects of decomposition, as some maintain, certainly have had their original forms thereby considerably changed.

Some kinds of caves, as those in certain sandstones and limestones, owe their origin to the destroying powers of the atmosphere.

The various changes in the form of rocks, by which they assume columnar, globular, tabular, indeterminate angular forms, and fall down into scales, crusts, layers, indeterminate angular grains, and sands, are, to a certain extent, effects of the destroying powers of the atmosphere.

To the destroying influence of the atmosphere valleys owe much of their present aspect. Their sides and summits, everywhere exposed to its action, become covered with debris; and, in this way, valleys sustain much greater changes than those which are produced on their bottom by the passage of the river, and on its sides by the rushing of its torrents.

But, besides these mechanical effects, many chemical destroying changes take place through the agency of the atmosphere. Felspar is often very liable to decomposition; it breaks down, and, finally, forms a kind of porcelain clay. During its decomposition, the alkali it contains is abstracted, and carried away by the atmospheric water. Other minerals are broken down and changed, by their absorbing some of the constituent parts of the atmosphere; thus, iron-pyrites, or sulphuret of iron, an insoluble substance, is in this way converted into sulphat of iron, a soluble salt; other minerals, as those abounding in iron, have their metallic ingredient changed from an oxide into a hydrate; and iron-pyrites, when contained in coal, sometimes, by its decomposition, gives it a burnt aspect.

FORMING EFFECTS OF WATER.

Mechanical Forming Effects.

1. *Rain Water.*—The forming effects of rain wa-

Geognosy. ter, in its course over the surface of the earth, are confined to the removal of loose earthy matters, and their deposition at the foot of the inclined planes down which it flows. When, however, the rains are violent and long continued, they carry along with them coarse gravel, and even rolled masses or boulders, of considerable magnitude. These effects taking place generally over the whole face of the earth, occasion considerable changes on its surface, by these removals and depositions of the disintegrated and broken rocky matter.

2. *Springs.*—Some springs deposite considerable quantities of muddy matter, and thus form flat, and sometimes even hilly tracks of country.

3. *Lakes.*—These give rise to great depositions of alluvial matter, and when they burst their barrier, at different times, leave on their sides series of terraces, or platforms, of which we have a fine example in the *parallel roads* of Glen Roy.

4. *Rivers.*—Rivers, in their ordinary state, when confined to their beds, do not give rise to any new formations; only it has been remarked, that, towards their mouth, they have a tendency to raise their beds. Very different is the case during floods, when they overflow their banks, and cover the neighbouring country with their waters. Then they roll along with their quantities of boulders, gravel, lime, and mud, which have been taken up from the soil over which they have passed, and these are gradually deposited over the surface of the country. The boulders are first deposited, next the gravel, and, lastly, the sand and mud. These sediments, accumulated during a long series of years, give rise to very considerable formations. The country along the banks of the Mississippi affords striking examples of the varieties and great extent of this mechanical forming effect of water. The vast plains on the sides of the Amazon River owe their formation in part to this effect of river water. Every hundred years, as we are informed by Girard, the Nile deposites on the soil of Lower Egypt a sediment of nearly five inches in thickness; and the flat lands there are composed of similar alluvial matters, and to an unknown depth. The water of rivers flowing over the same districts at different times, and not always conveying the same materials, have thus accumulated different substances above each other; and hence the alternations of beds of boulders, gravel, sand and clay, met with in countries formed by the alluvium of rivers. The soil of Egypt presents beds and veins of sand in the midst of the mud deposited by the Nile.

The beautiful holm, or haugh-lands, on the sides of our rivers, and which are often the richest parts of the country, have been formed by this mechanical agency of water. But these formations, although very considerable, are not the only ones effected by rivers. Besides the great deposites laid over the country they traverse, they carry along with them, to the shores of the ocean, and to the entrances of lakes, much disintegrated matter.

When any considerable river or stream enters a lake, a flat meadow track is formed, which continues to increase from year to year. The soil of this meadow is terminated by a marsh, which marsh is ac-

Geognosy.

quiring solidity, and is soon to be converted into a meadow, as the meadow will be into an arable field. All the while the sediment of the river makes its way hourly into the lake, forming a mound or bank under the surface of the water, with a pretty rapid slope towards the lake. This mound increases by the addition of new earth, sand, and gravel, poured in over the slope; and thus the process of filling up gradually advances. These phenomena are to be seen in all the lakes that receive rivers in this and other countries. This forming effect of water is very striking in the larger lakes. Thus, where the Rhone enters the Lake of Geneva, the beach has been observed to receive an annual increase, and the Portus Valaisæ, now Port Valais, which is at present half a league from the lake, was formerly close upon its banks. The great North American lakes are undergoing similar changes. In the course of ages lakes are filled up, when the country thus formed presents, in place of a lake, a plain traversed by the river. This change is effected partly by the filling up of the lake by the debris carried into it by the river, and partly by the draining off of the water by the deepening of the outlet. This latter is an operation which is generally visible. The stream, as it precipitates itself over the rocks, hurries along with it, not only sand and gravel, but also large blocks of stone, which grind and wear down the rocks, and materially assist the water in its deepening operation. Rivers, as already mentioned, carry to the sea-shore a portion of the loose matter removed from the surface of the earth by their destroying power. When they reach the sea, their velocity gradually diminishes, and is soon annihilated. As it diminishes, the coarse sand is deposited on the edges of the stream where the motion is least; and the finer particles are carried onwards to a distance from the coast. The alluvia formed in this manner at the mouths of rivers, and on their sides, by the current, are often very considerable. The Thames, Elbe, Rhine, and other rivers, afford striking examples of these formations. Prony informs us, that the River Po has so greatly raised the level of its bottom, since it was shut in by dikes, that its present surface is higher than the roofs of the houses of Ferrara. At the same time, the alluvial additions produced by that river have advanced so rapidly into the sea, that, by comparing old charts with the present state, the coast appears to have gained no less than 14,000 yards since the year 1604, giving an average of 180 to 200 feet yearly, and in some places the average amounts to 200 feet. The Nile, the Orinoco, and other great rivers in America, exhibit similar phenomena. At the mouth of the Mississippi large alluvial islands are formed, and, within the period of 100 years, the alluvial lands formed by it have extended several leagues into the sea.

The debris brought down by rivers when deposited in nearly inclosed seas, renders them shallower, and their borders are increased in extent. The Baltic has been computed to decrease in depth at the rate of forty inches in a hundred years. In proof of the increase of the shores of the Baltic, the following facts may be adduced. The Bay of Ful-

Geognosy.

backen, which was navigated by boats within the memory of man, is now filled up, and covered with grass. Several harbours in Lapland, that formerly admitted vessels, are now 3000 or 4000 paces from the sea; and at Helsingor, there are iron-works at places which were covered by the sea about eighty years ago. The whole of the ancient kingdom of Prussia appears to have been formed by alluvial depositions; it is said that the sea reached as far as Culm within the period of credible history. Dantzic, several hundred years ago, was close to the sea-shore. The Yellow Sea, which is a large gulf contained between the coast of China and the Peninsula of Corea, and which has somewhat of the character of such seas as the Baltic, receives so much mud from the great rivers that run into it, that it takes its colour, as well as its name, from that circumstance, and computations have been made of the time that it will require to fill up this gulf, and to withdraw it entirely from the dominion of the ocean; and these, although not very satisfactory, are considered as showing that it will be filled up in 240 ages.

The alluvial matter brought down by rivers, not only forms great tracks of land at their mouths, but also by the agency of currents, assisted by the waves of the ocean, gives rise to extensive tracks of low and flat land, which extend along the coast.

It is well known that the Mediterranean is at present one league from Aigues-Morte, in Provence, where St Louis embarked in 1269. Ravenna, which, in the time of Augustus, projected into the sea, is now nearly three miles from it; and the site of Venice and other similar situations will, in the course of time, experience the same fate. Spina had been originally built by the Greeks on the sea-coast; but in the time of Strabo, the sea was removed to the distance of ninety stadia. Adria, which gave name to the Adriatic, was, somewhat more than twenty centuries ago, the chief port of that sea, from which it is now at the distance of six leagues. The formation and increase of new grounds by alluvial depositions proceeds with equal rapidity along the coasts of the North Sea as on those of the Adriatic. These additions can easily be traced in Friesland and Groningen, where the epoch of the first dikes is well known to have been in the year 1570. An hundred years afterwards, the alluvial depositions had added in some places three-quarters of a league of new land on the outside of the dikes. The same phenomenon is distinctly observable all along the coasts of East Friesland, and the countries of Bremen and Holstein, as the period at which the new grounds were inclosed by the dikes for the first time is perfectly well known, and the extent that has been gained since it has been measured.

When the sea-coast is low, and the bottom consists of sand, the waves push this sand towards the shore, where, at every reflux of the tide, it becomes partially dried, and the winds, which often blow from the sea, drift up some portions of it upon the beach. By this forming effect of the ocean, downs, or ranges of low sand-hills, are formed along the coast. These accumulations of sand, if not fixed either by natural or artificial means, advance towards the interior of the country. In their progress inland, they push

Geognosy. before them great pools of water, formed by the rain which falls on the neighbouring grounds, and which has no means of running off, in consequence of the obstructions interposed by the downs. In several they proceed with a frightful rapidity, overwhelming forests, houses, and cultivated fields in their progress. M. Bremon tier, who made extensive works with a view of stopping the progress of the downs, in the south of France, estimated their progress there at sixty feet yearly, and in some places at seventy-two feet.

Sand-banks.—These also are to be considered as forming effects of water, and the general opinion is, that they are produced sometimes by the meeting of currents, and in other cases by depositions from currents interrupted by land, whether submarine or dry land. Thus the formation of the banks on the coast of Holland, and even of the Dogger Bank itself, is ascribed to the meeting of tides, by which a state of tranquillity is produced in the waters, and of consequence a more copious deposition of their sand and mud. The great bank of Newfoundland is conjectured to be a deposition from the waters of the Gulf Stream.

Chemical Forming Effects of Water.

Springs.—Certain spring waters, after dissolving, by means of the superabundant carbonic acid with which they are impregnated, calcareous earth abraded from limestone rocks, or rocks containing calcareous matter, allow the lime to crystallize, in consequence of the escape of the acid, and in this way form depositions of calc-sinter, or calcareous alabaster, on the roofs, sides, and floors of caves, or fill up fissures in rocks, and form veins, or when flowing over the surface of rocks, incrust them with calcareous sinter, or calcareous tuffa. The water of such springs, when collected in hollows so as to form lakes, often deposits vast quantities of calcareous tuffas, and hence these lakes, when dried up, present very extensive formations of these calcareous minerals. The *travertine* employed for building at Rome is a calcareous deposition from the waters of springs; and the town of Guancavelica, in South America, is built of a compact calcareous tuffa from the calcareous springs in the neighbourhood. The calcareous tuffa is most generally formed in open exposed places, but calcareous sinter chiefly in inclosed spaces, such as caves, &c. The peastone of mineralogists is formed from the waters of hot springs, as those of Carlsbad in Bohemia. The hot springs of Iceland, St Michael's, &c. deposit vast quantities of siliceous sinter, and this siliceous compound, although generally pure, is not always so, being occasionally intermixed with other minerals, and thus gives rise to particular mineral substances.

3. *Lakes.*—We have already noticed the calcareous depositions from the waters of some lakes, we shall now give an account of depositions of other kinds of minerals. The bog iron-ore of mineralogists is often found in such situations as to show it had been formed by deposition from the water of lakes; and in some countries it is collected from the sides and bottoms of lakes once in a certain number of years, thus showing that it is still forming in such situations. In

Geognosy. salt lakes considerable depositions of salt take place, and when such collections of water dry up, or are drained off, the sides and bottom of the cavities are found incrustated with salt, which is sometimes disposed in beds alternating with layers of clay.

4. *Marine Incrustations.*—Collections of sea shells are sometimes found agglutinated, and form banks or beds of considerable extent. But Cuvier remarks, we have no evidence that the sea has now the power of agglutinating these shells by such a compact paste, or indurated cement, as that found in marbles, or even in the coarse limestone strata in which shells are found enveloped. Still less do we now find the sea making any depositions at all of the more solid and siliceous strata which have preceded the formation of the strata containing shells. A compact calcareous alluvial rock is found in considerable abundance on the coasts of the West India islands, by the conglutination of fragments of shells and corals. The human skeleton from Guadaloupe, in the British Museum, is imbedded in rock of this description.

GENERAL ACCOUNT OF THE DIFFERENT CLASSES OF ROCKS.

Before the time of Lehman, the formations of which the crust of the earth is composed, were believed to be destitute of all regularity in distribution and in individual characters. That intelligent miner, however, was early convinced of the existence of a certain degree of order in their arrangement, and at length, in his well known work, first stated their division into *Primitive* and *Secondary*; under the first including those destitute of fossil organic remains, and which he considered as disposed in highly inclined strata, and as forming the most lofty, rugged, and hardest parts of the surface and interior of the earth; while under the other he arranged all those containing petrifications, or fossil organic remains, or which were associated with others containing such remains, and which, he says, are disposed in strata more horizontal, and form the lower and softer portions of the surface and interior of the earth. As geognosy advanced, new facts were added to those already known, and new arrangements and distributions of the formations were discovered. Werner first pointed out another class of rocks, which he named *Transition*, as they exhibit such characters as show the transition from those of the primitive to those of the secondary classes. These are interposed between the primitive and secondary classes, and are the first or earliest rocks of which the crust of the earth is composed, that afford fossil organic remains. The same illustrious naturalist examined with great care the various characters of those loosely cohering rocks of clay, marl, loam, &c. which rest on the more solid and older rocks of the secondary, transition, and primitive classes, and which form a fourth class, under the title *Alluvial*. The various mineral masses formed by the agency of volcanoes were but slightly noticed by Lehman, but claimed much of the attention of Werner, who formed them into a fifth class, under the title of *Volcanic*.

These different classes of rocks are met with in most extensive tracts of country, and every where

Geognosy. exhibit the same general relations. Thus the primitive rocks of Scotland, on a general view, do not differ from those of New Holland, and the rocks of the secondary class, although at first sight presenting much of a local character, are the same in all parts of the world where they have been hitherto met with.

I. *Primitive Rocks.*

The rocks of this class lie under those of the succeeding classes, and frequently, owing to the inequalities of their original surface, rise through them, and often to a great height, in the form of mountains and mountain chains. Countries composed of primitive rocks are in general more rugged and lofty than those of the other classes; further, their cliffs are more extensive, their valleys narrower and deeper, and more uneven than those in secondary countries. The strata of primitive mountains are very frequently highly inclined, a circumstance which contributes, in an especial manner, to the increase of the ruggedness and inequalities of the surface of primitive regions. The primitive strata in many countries maintain a wonderful uniformity of direction; thus, in Scotland, the general direction of the strata of the primitive mountains is from N. E. to S. W., and the same is the case nearly in the vast alpine regions of Norway, and in many of the lofty and widely extended primitive lands of other parts in Europe. In Scotland the direction is so invariable, not only in the primitive but also in the transition strata, that travellers may use it in place of a compass in guiding themselves through the mountain wilds of our Highland regions. The rocks of which primitive mountains and plains are composed are, throughout, of a crystalline nature, and present such characters as intimate their formation from a state of solution. These characters are the intermixture of the concretions of which these are composed at their line of junction, their mutual penetration of each other, their considerable lustre, pure colours, and considerable translucency. Thus, in granite, the concretions of felspar, quartz, and mica, are joined together without any basis or ground, and at their line of junction are either simply very closely attached together, or are intermixed, and frequently branches of the one concretion shoot into the other, thus occasioning a mutual interlacement, as is observed in bodies that have been formed simultaneously, and from a state of solution. These characters show that the concretions of granite, and the same applies to the concretions in limestone, gneiss, mica-slate, and other rocks of the primitive class, are of a crystalline nature, and have been formed at the same time.

The strata themselves are so arranged in mountains, that is, one set of strata including another, as to render it probable, that the seams of the strata are not a mechanical effect, but have been produced in the same manner as the seams of distinct concretions, or the surfaces of crystals. These strata, collected in groups, give rise to formations, such as gneiss or mica-slate; and in those cases where the rock is not distinctly stratified, it exhibits such characters as point it out in an unity or formation in the grand series, of which the crust of the earth is composed. The rock formations in primitive countries, although well marked

Geognosy. and distinguished by their general and particular characters, are not in any case isolated or unrelated to each other; on the contrary, we find, as they approach and join each other, gradual transitions of the one into the other, or intermixtures and interlacings at their great lines of junction. No true primitive rock appears foreign to the others, or exhibiting such characters as intimate a different mode of formation. Thus granite, which some consider a kind of lava, and therefore formed in different manner from gneiss or mica-slate, passes into and is intermixed with the surrounding rocks, and therefore has been formed in the same manner.

Primitive rocks are distinguished from those of the succeeding classes, by the absence of all fossil organic remains. This important fact allows us to infer, that organic beings had not been called into existence during the formation of primitive rocks, so that there was a time, in the history of the formation of our planet, when plants and animals did not exist. Although no traces of organic life occur in primitive rocks, yet they afford beds of a kind of coal (glance coal), almost entirely composed of carbon, a substance which many consider as peculiar to the organic kingdom, and which, they maintain, when found in the mineral kingdom, is to be traced to previously existing organic beings. This opinion is disproved, not only by the facts already mentioned, but also by the occurrence of carbon in hornblende, slate, and other minerals of the primitive class. Here then we have the formation of carbon, independent of the agency of animals and vegetables.

Limestone has been by many considered as entirely the result of animal action, and the various formations of that rock, whether in primitive or secondary mountains, are viewed as accumulations of altered shells or corals. But neither shells nor corals occur in primitive mountains, although they often contain extensive beds of limestone; and further, lime enters as a constituent part into most of the simple minerals of which primitive rocks are composed, facts which show that lime, like carbon, is an original substance in primitive mountains, and therefore has been formed at times independent of animals.

The two most abundant alkalies, viz. natron and potash, occur in primitive mountains, but of these, the potash is by far the most frequent and abundant. Before the discovery of potash in lepidolite, a primitive mineral, by Klaproth, this alkali was considered as entirely a production of the vegetable kingdom; but no vegetable remains occur in primitive rocks; and, therefore, in this case, the potash has been formed by some other agency than that of vegetation.

Phosphat of lime, which forms so important a constituent part of the higher animals, was long maintained to be exclusively a production of the animal kingdom; its after discovery in some vegetables, demonstrated that it also was occasionally produced in some tribes of plants; but still it was believed to be in every case either of animal or vegetable origin. But geologists, by the discovery of apatite, or phosphat of lime, in primitive mountains, have proved its existence in nature, independent of the agency of the organic kingdom.

Primitive rocks abound very much in metalliferous

Geognoſy. ſeous minerals, and hitherto no metal has been met with which does not occur excluſively, or occaſionally, in this claſs of rocks. Tin, wolfram, and molybdena, occur more frequently in theſe rocks than in other ſituations. Gold, ſilver, lead, copper, iron, cobalt, zinc, manganese, arsenic, and mercury, occur either diſſeminated, in beds, veins, or imbedded, in various rocks of this claſs, and many primitive diſtricts are particularly characterized by the metaliferous repositories they contain; thus, the primitive diſtrict of Strontian is characterized by its particular venigenous formation of galena, or lead-glance; the primitive country of Königsberg, in Norway, by its group of veins of ſilver-ore; and the primitive gneiss rocks of Arendal and Lapland, by their beds of magnetic iron-ore.

The moſt beautiful of all the productions of the mineral kingdom, the gems, occur in great variety in primitive rocks. Nothing can be more beautiful than the drusy cavities met with in primitive mountains, whoſe walls are lined with pure and variously coloured and crystallized topaz, beryl, and rock crystal; and the gneiss, granite, and mica-slate, with their imbedded grains and crystals of ſapphire, cryſoberyl, and garnet; and the veins in granite, clay-slate, and other primitive rocks, with their emeralds, axinite, and ſpinel ruby, afford to the mineralogist highly intereſting combinations.

But the moſt precious of all the gems, the diamond, is wanting in primitive regions. Judging of it from its ſplendid luſtre, pure and beautiful colours, high degree of tranſlucency, and great hardness, we would have expected it to occur in the cavities or veins of primitive rocks. But it is far otherwiſe, for it appears only in alluvial formations of gravel, clay, and ſand, of new formation, removed at an immenſe diſtance from thoſe that form the grand baſis of the cruſt of the globe; thus intimating its recent, and probably vegetable origin.

From what has been already ſaid, it is evident that the ſtudy of theſe rocks muſt be highly intereſting, in an economical point of view. Many of the richeſt and moſt important mines in the world are ſituated in primitive rocks; ſtatuary marble, and the various granites, porphyries, and ſerpentines, ſo much valued in the arts; and the gems, ſo diſtinguiſhed by their beauty of luſtre, colour, and great hardness, are principally contained in formations of the primitive ſeries.

Different Primitive Rocks.

The following are the rocks that occur in primitive mountains, viz. granite, porphyry, trap, ſerpentine, liſtmeſtone, gneiss, mica-slate, clay-slate, and quartz rock.

Theſe rocks are very ſimple in their nature, being generally compoſed of not more than five minerals, viz. quartz, felſpar, mica, hornblende, and liſtmeſtone. Some rocks are compoſed of but one of theſe ſimple minerals, as quartz rock; others of two, ſuch as mica-slate, which is a compound of mica and quartz; and others, as granite, conſiſt of three of them, viz. quartz, felſpar, and mica. In determining the ſpecies of primitive rocks, we muſt have an accurate acquaintance with the five ſimple minerals

already enumerated, and with the aſpects they aſſume when forming theſe aggregate mountain rocks. This being the caſe, nothing more is neceſſary than to refer the reader to the characters of theſe ſimple minerals given in the mineralogy of this article, and now to give ſhort characters of the rocks themſelves.

1. *Granite* is a granular compound of felſpar, quartz, and mica; *eyenite* is a variety of granite, containing, beſides the ingredients already enumerated, alſo hornblende.

2. *Porphyry* is an aggregate rock, having a baſis or ground containing imbedded grains and crystals of felſpar, and ſometimes of quartz and hornblende.

3. *Trap*.—All the rocks of the primitive claſs in which hornblende is the predominating ingredient are named trap. On expoſure to the air they aſſume the form of ſteps of a ſtair, hence the name *trap*. When the hornblende is aſſociated with felſpar, it forms *greenſtone*; if unmixed, *hornblende rock*; and if ſlaty, *hornblende ſlate*.

4. *Serpentine* is a dark green rock, with a ſplintery fracture, and glimmering or dull luſtre, tranſlucent on the edges, and ſo ſoft as to yield readily to the knife. It is conjectured to be a compound of felſpar, and of a mineral of the nature of hornblende, named diallage.

5. *Liſtmeſtone*.—This rock has generally a white or grey colour, is compoſed of ſhining granular concretions, and is more or leſs tranſlucent. It frequently contains ſcales of mica and grains of quartz.

6. *Gneiss* is a granular ſlaty compound of felſpar, quartz, and mica.

7. *Mica-slate* is a ſlaty compound of mica and quartz.

8. *Clay-slate* is a ſlaty rock, generally compoſed of extremely minute ſcales of mica. It is the roof ſlate ſo well known in the arts.

9. *Quartz-rock*.—This rock is almoſt entirely compoſed of quartz, either in granular concretions, or in the compact ſtate; and grains of felſpar and ſcales of mica are frequently contained in it.

II.—Transition Rocks.

Transition rocks ſucceed to the primitive, and are followed by thoſe of the ſecondary claſs. They generally, in this country, occupy a higher level than the ſecondary, but a lower one than the primitive formations. Their mountains, mountain-ranges, mountain-groups, and cliffs, are more rugged than thoſe of the ſecondary claſs, but are leſs rugged and ſofter in their outlines than the primitive rocks. Their valleys, too, are wider, and their ſides leſs rugged and abrupt, than in thoſe of primitive mountain-groups.

Moſt of the rocks are diſtinctly ſtratiſied, and the ſtrata are frequently vertical, and, like thoſe of the primitive claſs, exhibit the ſame general direction throughout great tracks of country. Thus the ſtrata in the great high land which ranges from St Abb's Head to the Iriſh Sea, and which is almoſt entirely compoſed of transition rocks, range every-where nearly from N. E. to S. W.

Although moſt of the transition rocks appear to have been formed from a ſtate of ſolution, and there-

Geognosy. fore possess the crystalline character, yet their crystallization appears to have been less perfect than in the primitive rocks, because the parts of which they are composed have a lower degree of lustre, inferior hardness, less translucency, and colours of less purity, than primitive rocks. In short, on a general view, we would say, these rocks have more of the earthy aspect, and of the fragmented character, thus intimating a lower degree of crystallization, than is observable in the primitive class. But transition rocks are further distinguished from those of the primitive class, by the very important circumstance of their containing fossil organic remains. These petrifications are of corals and shells, animal productions low in the zoological scale; and of vegetable remains that appear to belong to plants of the most simple construction, such as those of the class cryptogamia, and therefore at the bottom of the botanical scale. Hence it follows, that animals and vegetables of the more simple construction were those first called into existence, and that their creation did not take place until the period of the formation of transition rocks. Corals of the same nature as those met with in the preceding class also occur in transition rocks; and numerous and extensive beds of limestone, sometimes containing organic remains, are in some districts of frequent occurrence. Transition rocks frequently abound in ores of various descriptions, which are generally disposed in veins. The mining districts of the Leadhills and Wanlockhead, near Edinburgh, which are so rich in galena, or lead-glance, are situated in transition rocks. The rich lead and silver mines in the Hartz, and many of those in Mexico, are in rocks of the same description.

The gems which appear in so many interesting forms and relations in the strata and veins of primitive mountains, are comparatively rare in the present class.

The abundant occurrence of ores in this class of rocks; the extensive deposits of limestone, particularly of the variegated kinds so highly prized for ornamental purposes, which they contain; the fine granites and porphyries which they afford, are sufficient proofs of their importance in the arts.

The following are the rocks belonging to this class, viz. greywacke, clay-slate, limestone, trap, granite, syenite, porphyry, serpentine, gneiss, mica slate, and quartz-rock.

1. *Greywacke* is a conglomerated looking rock, with a basis of clay-slate, including angular and various shaped portions (by many considered as fragments) of clay-slate, flinty-slate, quartz, felspar, &c. and occasionally scales of mica. When the imbedded masses become small, and the mass slaty, it is named *greywacke-slate*.

2. *Clay-slate*.—This rock is of the same general nature with primitive clay slate, but differs from it in having less lustre, and in sometimes containing fossil plants and fossil shells.

3. *Limestone*.—It is more compact, and much smaller granular, and therefore has less lustre and lower translucency than the primitive limestone. It is frequently traversed by veins of calcareous spar, and often exhibits in the same bed various tints and shades of beautiful colours. Some varieties are con-

glomerated, forming the *brecciated marble* of artists, and others contain fossil shells and corals. Geognosy.

4. *Trap*.—This rock, like that of the primitive class, is principally composed of hornblende, and is sometimes associated with felspar, forming *transition greenstone*.

5. *Granite, Syenite, and Porphyry*.—These have the same composition as in the primitive class; and, independent of the characters derived from their mass, and their particular imbedded minerals and veins, are distinguished by the greywacke, with which they are associated.

6. *Gneiss and Mica Slate*.—These rocks occasionally occur associated with the greywacke and other members of this class.

7. *Serpentine and Quartz Rock*.—These very nearly resemble those of the primitive class, but are distinguished from them by their connection with greywacke, &c.

III.—Secondary Rocks.

This extensive and very interesting class of rocks rests immediately on those of the transition class, but when these are wanting, it rests on primitive rocks; and when the rocks of the two preceding classes occur in the same district with the secondary, the two former generally occupy a higher level. The hills of secondary districts are lower, rounder, with gentler acclivities, and fewer cliffs than those in transition districts; and their valleys are shallower, and their bottoms less inclined. Nearly all the secondary formations are more or less distinctly stratified, and the strata are more frequently horizontal, or slightly inclined, than in the older rocks. That regularity of direction of the strata, so prominent in the two preceding classes, has not been observed in the present.

Many of the secondary rocks, from their conglomerated structure, present a mechanical and not chemical aspect, and even the limestones of this series approach more nearly to the mechanical formation, than is observed in those of the preceding classes.

Secondary rocks are further particularly distinguished by the great variety and abundance of fossil organic remains which they contain. These extend throughout the whole secondary series, abounding in some formations as limestone, and in others as gypsum and trap, appearing rarely, and in small quantities. In the older formations, fossil remains of oviparous quadrupeds or lizards are met with, while, in the newer members of the series, remains of true quadrupeds, as of opossums, occur; and Werner, long ago, pointed out among the secondary formations the gradual rise of the animals in the zoological scale, according to the date of the formation in which their remains were found, viz. that in the oldest secondary rocks, the animal remains were of tribes lower in organization than those met with in formations in the middle of the series, and that those found in the newest members of the class were of animals much more perfect than those in the middle part of the series.

Coal, which we have already enumerated in the primitive and transition classes, occurs in great abundance in the secondary class, and, besides the glauconitic coal, the only kind of coal found in the formations older than the secondary class, contains also the black

Geognosy. or bituminous coal, which has much more the aspect of a vegetable formation than the glance-coal, and brown coal, a mineral of undoubted vegetable origin.

Secondary rocks are much less metalliferous than the transition and primitive, and hitherto the principal repositories of ore have been met with in the lower parts of the series, viz. in the mountain limestone, lower part of the coal formation, magnesian limestone, and in the lower part of the new red sandstone. The most abundant metals are iron, lead, and copper, and to these, as a metal of rather abundant occurrence, may be added zinc, in the form of calamine, mercury in form of cinnabar, and cobalt. It is in the secondary class of rocks that rock-salt first makes its appearance in quantity, and in the form of imbedded masses, and beds associated with gypsum and saliniferous clay.

The gems, as we have already remarked, are almost entirely confined to the primitive class, being of comparatively rare occurrence in transition rocks, and still less frequent in the rocks of this class.

From what has been already detailed, it is evident, that this class of rocks, from the variety and abundance of useful minerals it contains, must be highly interesting to those who attend to the uses of minerals. The greatest coal mines in this island, and in other countries, are situated in secondary rocks; the richest lead mines in England, the great iron mines in England and Scotland, and the salt of Cheshire, and of other countries, the vast quarries of sandstone, so important in building, and of greenstone, which furnishes the best paving stone hitherto discovered, and of limestone, so useful for various economical purposes, are situated in the formations of the secondary class.

The principal secondary rocks are sandstone, limestone, and trap, and these are arranged in various positions, and associated with other rocks.

We shall now enumerate them in the order of their relative position.

1. *First Sandstone, or Old Red Sandstone Formation.*—This is a reddish-brown sandstone, principally composed of particles of quartz, either without ground, or connected together by a basis or ground of iron shot-clay. It passes into greywacke, as on the coast of Galloway. It rests upon the rocks of the transition class.

2. *First Secondary Limestone, or Mountain Limestone.*—is a compact bluish-grey limestone, full of encrinurites, corals, and shells; often contains caverns, and sometimes alternates with the sandstone, slate-clay, and other rocks of the coal formation. It lies immediately on the old red sandstone.

3. *Coal Formation.*—This is an alternation of grey and white sandstone, bituminous shale and slate clay, clay ironstone, limestone, and coal. The whole together form a group or set of rocks, termed the coal formation. It rests on the mountain limestone.

4. *Second Secondary Limestone, or Magnesian Limestone of Geologists.*—This formation, as it appears in England, is generally a granular, sandy, and glimmering limestone, which contains a considerable portion of carbonate of magnesia. It occasionally contains gypsum and rock-salt. It lies immediately over or above the coal formation.

Geognosy. 4. *Second Sandstone, or New Red Sandstone Formation.*—This sandstone is principally composed of particles of quartz, set in a reddish-brown clayey basis or ground. It is looser in its nature than the old red sandstone, and its colour wants the bluish tint which occurs in the old red sandstone. It is sometimes conglomerated, particularly where near the magnesian limestone, when it contains fragments of the subjacent strata. It abounds in beds of red and blue marl and clay, and in these there are occasionally imbedded masses and beds of gypsum, and rock-salt. It is here, and in the magnesian limestone formation, that the greatest masses of rock-salt are met with, and it is in these formations of the secondary series that the principal salt mines are situated. It rests immediately on the second secondary or magnesian limestone.

5. *Third Secondary Limestone, or the Oolite or Shelly Limestone Formation, or Jura Formation.*—The lower members of this formation are blue, grey, and white slaty limestone, with blue slaty marl, and clay, in which are variously shaped masses of chert. These are known under the name *Lias*. Above these, still in this formation, there are alternations of beds of oolite limestone, shelly limestone, calcareous sandstone, various marls, clays, and fuller's earth. It rests upon the second or new red sandstone.

6. *Third Sandstone Formation, or the Green Sand Formation.*—This formation extends through a large portion of the south-eastern parts of England. Its characteristic member is a siliceous sandstone, abounding in grains of a substance resembling green earth or augite. Besides this sandstone, the formation contains beds of a coarse shelly limestone, of various clays, fuller's earth, and of iron sand. It rests upon the third limestone or oolite formation.

7. *Fourth Limestone Formation, or Chalk Formation.*—The lower part of this formation is composed of a grey clayey chalk, without flints, and of grey-coloured clays and marls. Immediately above is a hard chalk, with few flints, and above is the softer chalk in which flints and organic remains abound.

8. *Brown Coal Formation.*—In this formation, which appears to rest upon chalk, brown coal occurs in great masses, associated with clays and marls, and occasionally with glance coal. The English *pudding-stone* appears to rest immediately, either on the brown coal or the chalk formations.

9. *Paris Formation.*—Under this head we include the series of beds of clay, marl, limestone, gypsum, sand, and sandstone, that occur in the basin of Paris, and also in that of the Isle of Wight and other quarters. They lie above chalk, and higher than the brown coal, and are divided into sets; two characterized by the presence of fresh water shells, and remains of quadrupeds, are named *fresh water formations*; and other two, containing principally salt water shells, are named *marine formations*.

10. *Secondary Trap Rocks.*—The rocks of this division have been described by many geologists as lavas. They occur in imbedded masses, beds and veins, in many of the formations already described, and hence, in order to prevent repetition, we have brought them together under one division. They are principally composed of augite, with occasional

Geognosy hornblende, and felspar; the augite occurs in all its states from the crystalline to the earthy or powdery condition, and the felspar appears in all the different states from clay stone and clay to the crystalline state. The following are the secondary trap rocks: *Basalt, greenstone, syenite, amygdaloid, porphyry, and tuffa*, which are already described in the *Encyclopædia*.

Mon.ghan.

IV. Alluvial Rocks.

These are the various clays, loams, marls, sands, gravels, rolled masses, &c. which lie over the other more solid rocks, and which owe their origin to the agency of the waters of the ocean, of rivers, lakes, and springs. They are divided into those called *diluvian*, because they seem to have been formed at the time of the deluge; such are the clays, sands, and loams, containing the remains of elephants, rhinoceri, &c. and of those loose blocks sometimes 50,000 square feet in magnitude, and found at great

distances from their native places; and into those clays, loams, sands, and gravels, which are daily formed on the face of the earth by the agency of the waves of the ocean, and the actions of rivers, lakes, and springs, and which have been named *post-diluvian*.

Geognosy
Monaghan

V. Volcanic Rocks.

All those rocks which owe their present characters to the action of subterranean heat, or to that emanating from beds of coal, are named volcanic.

They are divided into *pseudo-volcanic*, and *true volcanic*. The *pseudo-volcanic* rocks are clays and iron stones, indurated, and partly melted by the heat from burning beds of coal. The *true volcanic* rocks are those which have flown in streams, or have been projected in the form of dust or gravel, from the craters or sides of volcanoes in a state of activity. These are the various kinds of *lava, tuffa, and volcanic dust*.
(M. M. M.)

Situation
and Extent

MOLLUSCA. See APPENDUM to this Volume.
MONAGHAN, a county of Ireland, in the province of Ulster, extending about 38 English miles from north to south, and 24 miles from east to west, contains 509 English square miles, or 325,760 English acres. It is situated in the diocese of Clogher, and ecclesiastical province of Armagh, and is divided into five baronies and 21 parishes. Its boundaries are Armagh and Tyrone on the north; Armagh, Meath, and Louth, on the east; Cavan and Louth on the south; and Fermanagh on the west.

Surface, &c.

The surface of this district is marked by a succession of low grounds and detached hills, which, in other quarters of no great height, attain a considerable elevation on the borders of Tyrone and Armagh; and a considerable space is occupied with bogs and small lakes. It has not the advantage of being much sheltered and ornamented with woods and inclosures, which both the soil and climate are said to require; yet it contains a few handsome seats, with considerable plantations around them; and towards the middle of the county there is a considerable tract of fertile land, with a subsoil of limestone gravel. In other parts, though the soil be rather wet, it is far from being unproductive. The rivers and rivulets are the Blackwater, the Fane, the Lagan, the Ballyhays, and a few others. Some of these flow westward to Loch Carne, and others eastward into the county of Louth; but none of them are of such importance as to require particular notice. The Blackwater is for some distance the boundary between this county and Tyrone. Limestone, sandstone, and marl, are spread throughout a great part of it. Some valuable quarries of sandstone have been long wrought among the hills on the north, near the boundary with Tyrone. In the same quarter very good millstones have been raised.

States.

Monaghan contains a few large estates, but the greater part of it is divided into small ones, many of which do not yield a free income equal to the ordinary wages of labour. A few years ago, there was only 172 freeholders of L. 50 and upwards, out of nearly 6000. Most of the considerable proprietors

are absentees, and very little of the landed property is in the hands of Catholics.

Farms were so small a few years ago, as not to *Para* average ten Irish acres over the whole county; and the management, as might be expected, was exceedingly unskilful and unproductive. The spade was used much more than the plough; the latter being an implement which, with the team required to work it, and the party to attend and direct it, could be brought into action only by the united efforts of several tenants. The general term of leases is 21 years, and a life, or sometimes three lives. The principal crops are oats, potatoes, and flax, with wheat and barley in a small proportion; these last, however, extend over a much greater tract now than they did a few years ago. They make a good deal of butter, but there are no large dairies. Goats are in greater numbers than sheep, which is of itself a sufficient proof of the low state of its agriculture.

Monaghan, however, has been long distinguished *Manufa* for its linen manufacture, which is said to have *atures* averaged, twenty years ago, about L. 200,000 a-year. It is carried on by the greater portion of the inhabitants of both sexes, all the small farmers being also weavers. This county has no other manufacture worth noticing, and little besides that can be spared for export, being more populous for its extent, owing to this minute division of land, than many others that are more productive. The towns and villages are Monaghan, the county town, Clones, Carrickmacross, Castle Blaney, Drum, Castle Shane, Ballybay, and Emyvale. The first sent two members to the Irish Parliament; but all of them being inconsiderable places, they have no share in the elections for the Parliament of the United Kingdom, to which the county itself sends two members. The Catholics are said to be to the Protestants as about 5 to 1, most of the latter being Presbyterians. In 1790, Monaghan contained 118,000 inhabitants, which is nearly 232 for every English square mile.—See the general works quoted under the former Irish counties, and Sir Charles Coote's *Statistical Survey of Monaghan*.
(A.)

MONEY.

Money.

THE term *MONEY** is used to designate whatever commodity the inhabitants of any particular country, either voluntarily or by compulsion, accept as an equivalent for their labour, and for all the commodities they have to dispose of.

SECT. I.—Circumstances which led to the use of money—Principal properties that every commodity used as such ought to possess—Not a sign or a measure of value, but a real equivalent.

Circumstances leading to the use of money

A country in which the division of labour was unknown, and where every individual or family directly produced the commodities necessary for his or their consumption, would have no exchanges, and consequently no money. But, after the division of labour has been established, the introduction of money becomes necessary, or, at least, highly advantageous. In such a state of society, a very small part only of a man's wants are directly supplied from the produce of his own labour. The greater part are indirectly supplied by exchanging that surplus part of the produce of his own labour which exceeds his own consumption, for such parts of the produce of other men's labour as he has occasion for, and they are willing to part with. Every man thus lives by exchanging, or becomes in some measure a merchant, and the society itself grows to be what is properly a commercial society.

"But when the division of labour first began to take place, this power of exchanging must frequently have been very much clogged and embarrassed in its operations. One man, we shall suppose, has more of a certain commodity than he himself has occasion for, while another has less. The former, consequently, would be glad to dispose of, and the latter to purchase, a part of this superfluity. But, if this latter should chance to have nothing that the former stands in need of, no exchange can be made between them. The butcher has more meat in his shop than he himself can consume, and the brewer and the baker would each be willing to purchase a part of it; but they have nothing to offer in exchange except the different productions of their respective trades, and the butcher is already provided with all

the bread and beer which he has immediate occasion for. No exchange can, in this case, be made between them. He cannot be their merchant, nor they his customers; and they are all of them thus mutually less serviceable to one another. In order to avoid the inconveniency of such situations, every prudent man, in every period of society, after the first establishment of the division of labour, must naturally have endeavoured to manage his affairs in such a manner as to have at all times by him, besides the peculiar produce of his own industry, a certain quantity of some one commodity or another, such as he imagined few people would be likely to refuse in exchange for the produce of their industry."—(*Wealth of Nations*, Vol. I. p. 34. 8vo Ed.)

This commodity, whatever it may be, is money.

An infinite variety of commodities have been used as money in different countries and states of society. Those nations who chiefly subsist by the chase, such as the ancient Russians, and the greater part of the Indians who now occupy the uncultivated portion of America, use the skins of wild animals as money.† In the pastoral state of society cattle are most commonly used for that purpose. Homer mentions that the armour of Diomed cost only *nine* oxen, while that of Glaucus cost *one hundred*. (*Iliad*, lib. 6, lin. 235.) The etymology of the Latin word (*pecunia*), signifying money, and of all its derivatives, proves that cattle (*pecus*) had been the primitive money of the Romans.‡ They had also been used as such by the ancient Germans; for their laws uniformly fix the amount of the penalties to be paid for particular offences in cattle. (Storch *in loco citato*.) In remoter ages corn was very generally used, in agricultural countries, as money; and even now, it is by no means uncommon to stipulate for corn rents and wages. Other commodities have been used in different countries. Salt is said to be the common money of Abyssinia (*Wealth of Nations*, I. p. 35); a species of shells, called *cowries*, gathered on the shores of the Maldivé Islands, are used in smaller payments throughout Hindostan, and form the only money of extensive districts in Africa. § Dried fish forms the money of Iceland and Newfound-

Money.

Commodities used as money in different countries.

* Etymologists differ in opinion respecting the derivation of the word money. Some contend that it comes from *Monere*,—to admonish, to inform,—because the stamp impressed on coined money indicates its weight and fineness. (Bouterou, *Recherches sur les Monnoyes de France*, p. 1.) And others that it originates in the circumstance of silver being first coined at Rome in the temple of admonishing Juno—*Juno Moneta*. (Suidas, *in voce Moneta*.)

† Storch, *Traité d'Economie Politique*, Tome III. p. 16; and Ulloa, *Mémoires Philosophiques sur l'Amérique*, Tome II. p. 100.

‡ Morellet, *Prospectus d'un Nouveau Dictionnaire de Commerce*, p. 115.

§ "Dans les pays où le cuivre a trop de valeur pour pouvoir représenter celle des plus menues denrées, on est encore obligé de lui substituer quelque autre matière plus commune. C'est cette circonstance qui a fait adopter aux Indiens l'usage des *cauris* en guise de petite monnaie. Cet usage pourroit paroître étrange dans les pays aussi riches et d'une civilisation aussi ancienne que le Bengale et l'Indoustan: mais le cuivre y est si rare, et les vivres y sont à si bon marché, qu'une pièce de la valeur de 1 cop. et $\frac{1}{2}$ (about a halfpenny

Money.
Coined Money not a sign, or a measure of value.

calculated, the wealth of civilized communities." (Torrens on the Production of Wealth, p. 305.)

But, whatever may be the advantages attending the use of coined money, and they are great and obvious, it is necessary to observe, that its introduction does not affect the nature of exchanges. Equivalents are still given for equivalents. The exchange of a quarter of corn for an ounce of pure unfashioned gold bullion, is undeniably as much a real barter, as if it had been exchanged for an ox, or a barrel of beer. But, supposing the metal to have been formed into a coin,—that is, marked with a stamp indicating its weight and fineness, it is plain that circumstance could have made no change in the terms of the barter. The coinage would save to both parties the trouble of weighing and assaying the bullion, but it could do nothing more. *A coin is merely a piece of metal of a known weight and fineness*; and the commodities exchanged for it are always held by the parties to be of equal value. And yet these simple and obvious considerations have been very generally overlooked. Coined money, instead of being viewed in the same light as other commodities, has been looked upon as something quite mysterious. It was said to be both a *sign* and a *measure* of value. In truth, however, it is neither the one nor the other. A guinea is not a sign, it is the thing signified. A promissory note, payable at some stated period, may not improperly be considered as the *sign* of the specie which is to be paid for it; but that specie is itself a commodity possessed of real exchangeable worth. It is equally incorrect to call money a measure of value. Gold and silver do not measure the value of commodities, more than commodities measure the value of gold and silver. Every thing possessed of value may either measure, or be measured by, every other thing possessed of value. When one commodity is exchanged for another, each is the measure of the value of the other. If the quartern loaf sold for a shilling, it would be just as correct to say, that a quartern loaf measured the value of a shilling, as to say that a shilling measured the value of a quartern loaf.

Use of Gold and Silver as standard estimating the relative value of commodities.

The quality of serving as a measure of value is, therefore, equally inherent in every commodity. But the slow degrees by which the precious metals change their value, renders them peculiarly well fitted for forming a *standard*, by which to compare the values of other and more variable commodities. To this standard reference is almost always made in estimating the value of the products of every civilized country. We do not say, that one man is worth a thousand acres of land, and that another is worth a thousand sheep; but we ascertain for how much gold or silver the land and the sheep would exchange, and then say, that their proprietors are worth so much money. In this, however, there is certainly nothing mysterious. We merely compare the value of one commodity with the value of another commodity; and as coin or money has been found to be the most convenient standard of comparison, the value of all other commodities is usually estimated in it.

Proof of the non-existence of an

It is obvious, from this statement, that the terms of the exchange of one commodity, or set of commodities, for another may be adjusted, with reference

to money, without any money being actually in the possession of either of the parties making the exchange: If a horse, for example, had commonly sold for ten pieces of silver, an ox for five pieces, and a sheep for one piece, it would mark their relative values to each other, and the animals might be exchanged, on this footing, without the intervention of money. The frequent recurrence of transactions of this kind seems to have given rise to the notion of an *abstract or ideal* standard of value. Thus, instead of saying that a horse is worth ten pieces of silver, an ox five pieces, and a sheep one piece, it has been contended that it might equally have been said that they were respectively worth ten points or units, five points or units, and one point or unit; and that, as the proportional values of commodities might be as clearly expressed in these *arbitrary* terms as in money, or any commodity possessed of real value, the use of the latter, as a standard, might be advantageously dispensed with, and a set of abstract terms adopted in its stead. This, however, is entirely and completely mistaking the nature and object of a standard. A standard is *not* intended to mark the known relations between different commodities, but to enable us easily to discover those which are unknown. Now, although a series of arbitrary terms may serve extremely well for the first of these purposes, it is utterly impossible that they can ever serve for the second. This, however, is exclusively the object of a standard; and it is quite plain that nothing can be used as such which is not possessed of the same properties with those with which it is to be compared. To measure length, a standard must have length, to measure value it must have value. The value of commodities is ascertained by separately comparing their cost with the cost of money, and we express their relation to each other by simply stating the result of our inquiries; that is, by mentioning the number of livres, of pounds, or of fractions of a pound, they are respectively worth. And, when any new commodity is offered for sale, or when any change is made in the cost of an old one, we ascertain their relation to the rest, by merely comparing them with a livre or a pound. It is plainly impossible, however, that we could have done this, had the terms livre, or pound, been purely arbitrary, and referable to no really valuable commodity! We might as well try to estimate distances by an imaginary inch, or an imaginary foot, as to estimate prices or values by an imaginary shilling, or an imaginary guinea. When we say that an ox is worth five pounds, and a sheep only one, we really mean no more than that, when an ox and a sheep are compared together, that is, when the one serves as a *standard by which to estimate the value of the other*, one ox is found to be worth five sheep. But, suppose that we wish to ascertain what is the relative value of some other commodity,—of a pound of tea, for example,—to oxen or sheep, of what use would it be to be told that one ox was worth five sheep, or that, when the value of an ox was represented by the imaginary term "five pounds," the value of a sheep was represented by the imaginary term "one pound?" It is not the relation between oxen and sheep, but the relation between these animals and tea, that we are desirous of learning. And, al-

Money.
abstract or ideal standard.

Money. though this relation may be learned by comparing the cost of producing oxen and sheep with the cost of producing tea, or by ascertaining for how much of some other commodity an ox, a sheep, and a pound of tea, will respectively exchange, it is obvious it could never be learned by comparing them with a set of arbitrary terms or symbols! It would not, in truth, be more absurd to attempt to ascertain it by comparing them with the hieroglyphics on an Egyptian sarcophagus. Nothing that will not exchange for something else, can ever be a standard, or measure of value. Commodities are always compared with commodities, and not with abstract terms. Men go to market with real values, and not with the signs of values, in their pockets. And it is to something possessed of real worth—to the gold contained in a guinea, and not to the word guinea, that they always have referred, and must continue to refer, in estimating value. *

In common mercantile language, the exchanging of

money for a commodity is termed *buying*, and the exchanging of a commodity for money *selling*. *Price*, unless when the contrary is particularly mentioned, always means the value of a commodity, estimated in money.

Having thus endeavoured to explain the circumstances which led to the introduction of money, and to show what it really is, and what it is not, we shall now proceed to investigate the laws by which its exchangeable value is regulated. It is chiefly from the prevalence of erroneous opinions on this subject, that the true theory of money has been so long misunderstood.

SECT. II.—Circumstances which Regulate the Exchangeable Value of Money.

This branch of our subject naturally divides itself into two parts; 1st, An inquiry into the principles which regulate the exchangeable value of money

* The following passage of Montesquieu has been often referred to in proof of the existence of an ideal standard:—"Les noirs de la côte d'Afrique ont un signe des valeurs sans monnaie; c'est un signe purement idéal fondé sur le degré d'estime qu'ils mettent dans leur esprit à chaque marchandise, à proportion du besoin qu'ils en ont—une certaine denrée, ou marchandise vaut trois macutes; une autre, six macutes; une autre, dix macutes: c'est comme s'ils disoient simplement trois, six, dix. Le prix se forme par la comparaison qu'ils font de toutes les marchandises entre elles: pour lors, il n'y a point de monnaie particulière, mais chaque portion de marchandise est monnaie de l'autre."—(*Esprit des Loix*, Livre XXII. cap. 8.)

But, instead of giving any support to the notion of an abstract standard, this passage might be confidently referred to in proof of its non-existence. Had Montesquieu said that the blacks determined the relative values, or prices, of commodities, by comparing them with the arbitrary term *macute*, the statement, though false, would have been, at least, in point. But he says no such thing. On the contrary, he states distinctly, that the relative values of commodities (marchandises) are ascertained by comparing them *with each other* (entre elles), and that it is merely the result of the comparison that is expressed in arbitrary terms!

So much for the weight to be attached to this statement, supposing it to be well-founded. The truth is, however, that the term *macute* is not really arbitrary, and employed only to mark an ascertained proportion, but that it has a reference to, and is, in fact, the name of an intrinsically valuable commodity. "On a bien dit," says l'Abbé Morellet, "que ce mot *macute* étoit une expression abstraite et générale de la valeur, et cela est vrai au sens où nous l'expliquerons plus bas; mais on n'a pas remarqué que cette abstraction a été conséquente et postérieure à l'emploi du mot *macute* pour signifier une marchandise, une denrée réelle à laquelle on avoit longtems comparé toutes les autres."

"Macute en plusieurs lieux de la côte d'Afrique, est encore le nom d'une certaine étoffe—'Chez les nègres de la côte d'Angola,' dit le voyageur Angelo, 'les macutes sont des pièces de nattes d'une aune de long;—'Jobson dit aussi que les macutes sont une espèce d'étoffe. *

"Les étoffes ont toujours été l'objet d'un besoin très-pressant chez des peuples aussi barbares, dépourvus de toute espèce d'industrie.—Les nattes en particulier leur sont de la plus grande nécessité. Elles sont divisées en morceaux peu considérables et d'une petite valeur—elles sont très-uniformes dans leurs parties, et les premières qu'on a faites auront pu être semblables les unes aux autres, et d'une bonté égale, sous la même dénomination—toutes ces qualités les ont rendu propres à devenir la mesure commune des valeurs."—(*Prospectus d'un Nouveau Dictionnaire de Commerce*, p. 121.)

The following extract from Park's *Travels* gives an example of a similar kind: "In the early intercourse of the Mandingoes with the Europeans, the article that attracted most notice was iron. Its utility in forming the instruments of war and husbandry made it preferable to all others; and iron soon became the measure (standard) by which the value of all other commodities was ascertained. Thus a certain quantity of goods, of whatever denomination, appearing to be equal to a bar of iron, constituted, in the trader's phraseology, a bar of that particular merchandise. Twenty leaves of tobacco, for instance, were considered as a bar of tobacco; and a gallon of spirits (or rather half spirits and half water) as a bar of rum; a bar of one commodity being reckoned equal in value to a bar of another commodity. As, however, it must unavoidably happen, that, according to the plenty or scarcity of goods at market, in proportion to the demand, the relative value would be subject to continual fluctuation, greater precision has been found necessary; and, at this time, the current value of a single bar of any kind is fixed by the whites at *two shillings Sterling*. Thus, a slave, whose price is L.15, is said to be worth 150 bars."—*Travels in the Interior of Africa*, 8vo edit. Vol. I. p. 39.)

Money.

when the power to supply is not monopolized; and, 2d, An inquiry how far these principles are liable to be affected by the operation of monopoly.

Cost of Production regulates the exchangeable value of Money, when the power to supply it is not monopolized.

I. There does not now seem to be much room for difference of opinion respecting the circumstances regulating the value of the precious metals, and their distribution throughout the various countries of the globe. Bullion is a commodity, on the production of which competition operates without restraint. It is not subjected to any species of monopoly, and its value in exchange must, therefore, be entirely regulated by the cost of its production, that is, by the comparative quantities of labour necessary to bring a given quantity of it to market.

If, in every stage of society, it required precisely the same quantity of labour to produce a given quantity of bullion, its value would be *invariable*; and it would constitute a standard by which the variations in the exchangeable value of all other commodities could be *correctly* ascertained. But this is not the case either with bullion or any other commodity. And its value, in the same way as the value of any other commodity, fluctuates not only according to the greater or less productiveness of the mines from which it is extracted, but also according to the comparative skill of the miners, and the improvements of machinery.

M. Say has, in his valuable work on *Political Economy*, a chapter, "De la valeur que la qualité d'être monnaie ajoute à une marchandise." But a little reflection will convince us, that M. Say is mistaken, and that the circumstance of the precious metals being used as money, or as a circulating medium, cannot affect their exchangeable value. M. Say reasons on the common hypothesis, that an increase of demand is always productive of an increase of value,—an assumption totally at variance with principle and with fact. Value depends exclusively upon the cost of production; and it is obvious, that the cost of producing a commodity may be diminished at the same time that the demand for it is increasing. This is so plain a proposition, as hardly to require to be substantiated by argument. And a reference to the case of cotton goods, the price of which has, notwithstanding the vast increase of demand, been constantly on the decline during the last half century, is enough to convince the most sceptical of the extreme erroneousness of M. Say's conclusion. But, with regard to the particular case of the precious metals, it is clear the capital devoted to the production of gold and silver must yield the common and ordinary rate of profit; for, if it yielded more than this rate, there would be an influx of capital to the mining business; and, if it yielded less, it would be withdrawn, and invested in some more lucrative employment. And hence, though the demand for gold and silver should, from the adoption of some other commodity as an instrument of exchange, gradually become less, the value of the precious metals would not, on that account, be reduced. A smaller supply would, indeed, be annually brought to market, and a portion of the capital formerly engaged in the mining, refining, and preparing of the metals would be disengaged; but as the whole stock thus employed yielded only the aver-

Money.

age rate of profit, the portion which is not withdrawn must continue to do so,—or, which is the same thing, gold and silver must still continue to sell for the same price. It is no doubt true, that where mines are, as they almost always are, of different degrees of productiveness, any great falling off in the demand for bullion might, by rendering it unnecessary to work the inferior mines, enable the proprietors of the richer mines to continue their work, and to obtain the ordinary rate of profit on their capitals, by selling their bullion at a reduced price. In this case the value of bullion would be really diminished; but it would be diminished, not because there was a falling off in the demand, but because there was a greater facility of production. On the other hand, an increased demand for bullion, whether it arose from the general suppression of paper money, or from a greater consumption of gold and silver in the arts, or from any other cause, would not—unless it was necessary, in order to procure the increasing supply, to have recourse to mines of an inferior degree of productiveness—be accompanied by any rise of price. If the mines from which the additional supplies were to be drawn were less productive than those already wrought, more labour would be necessary to procure the same quantity of bullion, and, of course, its price would rise. But, if no such increase of labour was required, its price would remain stationary, though a thousand times the quantity formerly required should be demanded.

After gold and silver have been brought into the market, whether they shall be converted into coin or into manufactured commodities, depends entirely on a comparison of the profits that may be derived from each operation. No person would take bullion to the mint if he could realize a greater profit by disposing of it to a jeweller; and no jeweller would work up bullion into plate, if he could turn it to greater account by converting it into coin. The value of bullion and coin must, therefore, in countries where the expences of coinage are defrayed by the state, nearly correspond. When there is any unusual demand for bullion in the arts, coin will be melted down; and when, on the contrary, there is any unusual demand for coin, plate will be sent to the mint, and the equilibrium of value maintained by its fusion.

It appears, therefore, that while competition is allowed to operate without restraint on the production of gold and silver, they are, like all other commodities, produced in similar circumstances, valuable only in proportion to the cost of their production,—that is, in proportion to the quantity of labour necessarily expended in bringing them to market. And hence, while they constitute the currency of the commercial world, the price of commodities, or their value compared with gold or silver, will vary, not only according to the variations in the exchangeable value of the commodities themselves, but also according to the variations in the exchangeable value of the gold or silver with which they are compared.

II. But if competition was not allowed to operate on the production of the precious metals, if they could be monopolised and limited in their quantity, their exchangeable value would no longer be regulated by the proportion between the supply and demand regulates the exchange-

the same principles. If, after the limitation, they still continued to be used as money, and if, in consequence of the improvement of society, manufactured commodities and valuable products should be very much multiplied, the exchanges which this limited amount of money would have to perform would be proportionably increased; and, of course, a proportionably smaller sum would be appropriated to each particular transaction; or, which is the same thing, money prices would be diminished. Whenever the supply of money is fixed, the amount of it, given in exchange for commodities, must vary inversely as the demand, and can be affected by nothing else. If double the usual supply of commodities were brought to market in a country with a limited currency, their money price would be reduced one-half; and if only half the usual supply were brought to market, it would be doubled; and this, whether the cost of their production had increased or diminished. No one would, in these circumstances, exchange the produce of his industry for money, on the ground that money was itself a commodity capable of being advantageously used in the arts, or that an equal quantity of labour had been expended on its production; but because it was the universal equivalent used by the society, and because, as such, it would be willingly received in exchange for the produce of the industry of others. The remark of Anacharsis, the Scythian, that gold and silver coins seemed to be of no use but to assist in numeration and arithmetic (*Ilume's Essay on Money*), would, if confined to a strictly limited currency, be as just as it is ingenious. Guineas, sovereigns, livres, dollars, &c. would then really constitute mere tickets or counters, to be used in computing the value of property, and in transferring it from one individual to another. And as small tickets, or counters, would serve for this purpose quite as well as large ones, it is unquestionably true, that a debased currency might, by first reducing, and then limiting its quantity, be made to circulate at the value it would bear if the power to supply it was unrestricted, and if it were possessed of the legal weight and fineness; and that, by still further limiting its quantity, it might be made to pass at any higher value.

Thus it appears, that whatever may be the material of the money of any country, whether it consist of gold, silver, copper, iron, leather, salt, cowries, or paper, and however destitute it may be of all intrinsic value, it is yet possible, by sufficiently limiting its quantity, to raise its value in exchange to any conceivable extent.

Suppose the money of Great Britain to consist of 50,000,000 or 60,000,000 of one pound notes, and that we are prevented from increasing or diminishing this sum, either by issuing additional notes or coins, or by withdrawing the notes already in circulation, it is obvious that the quantity of commodities for which such notes would exchange, would increase or diminish precisely according to the increase or diminution of the quantity of commodities brought to market. If we suppose that ten times the amount of products that were offered for sale when the limitation of the currency took place, are offered for sale

ten or twenty years afterwards, and that the rapidity of circulation has continued the same, prices will have fallen to one-tenth of their former amount; or, which is the same thing, the exchangeable value of the paper money will have increased in a tenfold proportion:—and, on the other hand, if the products brought to market had diminished in the same proportion, the exchangeable value of the paper money will have been equally reduced.

The principles we have now stated are of the utmost importance to a right understanding of the real nature of money. Previously to the publication of Mr Ricardo's great work, every writer of authority on political economy had maintained that the value of money depended entirely on the relation between its amount and the demand. But this is true only of a gold or silver currency when its quantity is limited, and of a currency formed of materials having little intrinsic worth, as paper, when its quantity is limited, and when it is not made convertible, at the pleasure of the holder, into some more valuable commodity, whose production is under no restraint. It is obvious, indeed, without any reasoning on the subject, that the value in exchange of a currency possessed of little or no real value, can only depend on the proportion which its total amount bears to the amount of the commodities brought to market, or to the demand. And wherever a currency of this kind, or a limited gold currency, is in circulation, the common opinion that the prices of commodities are regulated exclusively by the proportion between the quantity of them brought to market, and the supply of money, and that any considerable increase or diminution of either will proportionably affect prices, is quite correct. It is altogether different, however, with a currency consisting of gold or silver, or of any other commodity possessed of considerable value, and the supply of which may be increased to an unlimited extent by the operation of unrestricted competition.

The fluctuations in the supply of, and demand for, such money, can have no permanent effect on its exchangeable value; this depends exclusively on the comparative cost of its production. If a guinea commonly exchanges for a couple of bushels of wheat, or a hat, it is because the same labour has been expended on its production, as on that of either of these commodities; while, if with a limited and inconvertible paper money, these commodities exchange for a guinea note, it would only be because such was the proportion which, as a part of the general mass of commodities offered for sale, they bore to the supply of paper or money in the market. This proportion would, it is evident, be not only immediately, but permanently, affected by an increase or diminution of the supply either of paper or of commodities. But the relation which commodities bear to a freely supplied metallic currency, could not be permanently changed, except by a change in the cost of producing the commodities or the metals.

Our readers must not conceive from what we have now stated, that we mean to contend that the value of gold or silver is never affected by variations in the supply and demand. Such an opinion would be al-

Money. together erroneous. At the same time it must be admitted, that their value is much less affected by such variations, than the value of almost any other commodity. Their great durability precludes the possibility of any sudden diminution of their quantity, while the immense surface over which they are spread, and the various purposes to which they are applied, prevent any unusual productiveness of the mines from speedily lowering their value. An extraordinary event, such as the discovery of America, or the establishment of an intercourse between a country where bullion bore a high value, and one where its value, from the greater facility of its production, was comparatively low, would, by causing a sudden exportation and importation, raise its value in the one country, and sink it in the other. But such events must necessarily be of very rare occurrence. And although the value of gold and silver must, because of the different degrees of productiveness of the mines, to which, in the progress of society, recourse must be had,—and because of the successive improvements in the art of mining and working metals, be very different at distant periods—it is abundantly uniform to secure us against all risk of sudden and injurious fluctuations.

Such are the circumstances which regulate the value of money, both when the power to supply it is not subjected to any species of monopoly, and when it is monopolised and limited. In the former case, its value depends, like the value of all other commodities, on the cost of its production; while, in the latter case, its value is totally unaffected by that circumstance, and depends entirely on the extent to which it has been issued, compared with the demand.

The conclusions deducible from the fundamental principle we have thus endeavoured to establish, are of the utmost importance. A metallic currency, on the coinage of which a high seignorage or duty was charged, and a paper currency not convertible into the precious metals, were occasionally seen to circulate at the same value with a metallic currency of full weight, and which had been coined at the expence of the state. But no rational, satisfactory, or consistent explanation of these apparently anomalous results could be given until the effects produced by limiting the supply of money had been accurately observed and appreciated. Now, however, that this has been done, all these difficulties have disappeared. The theory of money has been perfected, and we are enabled to show what, under any given circumstances, would be the effect of imposing a seignorage, or of issuing an inconvertible paper currency.

SECT. III.—*A moderate Seignorage on Coined Money shown to be advantageous.—Principles which should regulate its amount.**

Reasons why The government of almost every country has re-

tained the power of coining exclusively in its own hands. In antiquity this privilege was reserved merely to prevent the confusion that must have attended the too great multiplication of coins of different denominations, had individuals been permitted to issue them at their pleasure, and to give the public a greater security that the stamp should truly indicate the weight and fineness of the metal.† But in modern Europe it has been used not only as a means of affording a better guarantee to the public, but also of increasing the revenues of the state. Of the expediency of deriving a revenue from this source, much difference of opinion has, however, existed. Many able economists have contended that the state ought in no circumstances to charge any duty on coined money; and that the expences of the mint ought always to be defrayed by the public. In this opinion we cannot concur; and we think the reasoning of Dr Smith, in favour of a moderate seignorage, quite unanswerable. No good reason has yet been given why those who want coins should not have to pay the expences of manufacturing them. Coinage, by saving the trouble and expence attending the weighing and assaying of bullion, indisputably adds a real value to the precious metals. It renders them fitter to perform the functions of a circulating medium. A guinea is of greater real value than a piece of pure unfashioned gold bullion of the same weight; and for this plain reason, that while it is equally well adapted with the bullion for being used in the arts, it is much better adapted for being used as money, or in the exchange of commodities. Why then should the Government be prevented from charging a seignorage, or duty on coined money, equal to the expences of the coinage, or, which is the same thing, to the value which it adds to the bullion? Those who contend that the State ought to defray the expence of the coinage, might, with equal cogency of reasoning, contend that it ought to defray the expence of manufacturing gold and silver tea-pots, vases, &c. In both cases, the value of the raw material, or bullion, is increased by the cost of workmanship. And it is only fair and reasonable, that those who carry bullion to the mint ought, equally with those who carry it to the jewellers, to be obliged to pay the expences necessarily attending its conversion into coin.

But there are other reasons why a seignorage, to this extent at least, ought to be exacted. In countries where the expences of coinage are defrayed by the State, an ounce of coined gold or silver, and an ounce of gold or silver bullion, must be very nearly of the same value. And hence, whenever it became profitable to export the precious metals, money, in the coinage of which a considerable expence had been incurred, would be sent abroad indifferently with bullion. It has indeed been attempted, by pro-

Money.
Seignorage should be imposed on Coined Money.

* Seignorage, strictly speaking, means only the clear revenue derived by the state from the coinage; but it is now commonly used to express every deduction made from the bullion brought to the mint to be coined, whether on account of duty to the state, or of the expence of coinage (properly *brassage*). We always use the phrase in its more enlarged sense.

† Le Blanc, *Traité Historique des Monnoyes de France*, p. 90, ed. Amst. 1692.

Money. **hibiting the exportation of coins, to prevent the loss which might thus be occasioned to the public; but these efforts have proved singularly ineffectual. Admitting, however, that it is possible, which most certainly it is not, to prevent or even materially to limit the clandestine exportation of coins, it is conceded, on all hands, to be quite nugatory to attempt to prevent their conversion into bullion. In this there is almost no risk. And the security with which their fusion can be effected, and the trifling expences attending it, will always enable them to be melted down and sent abroad whenever there is any unusual foreign demand for the precious metals. This exportation would, however, be effectually prevented by the imposition of a seignorage or duty, equal to the expence of the coinage. The coins being, by this means, rendered more valuable than bullion, they would be always kept at home in preference: And if, as Dr Smith has observed, it became necessary, on any emergency, to export coined money, it would be again reimported. Abroad the coins would be only worth so much bullion; while at home they would be worth this much and the expence of coinage besides. There would, therefore, be an obvious inducement to bring them back, and the supply of currency would be maintained at its proper level, without its being necessary for the mint to issue fresh coins.**

Besides relieving the country from the useless expences attending the coinage of such money as may be melted down and exported to other countries as an article of commerce, the imposition of a moderate seignorage would either totally prevent, or at least lessen that fusion of the heavier coins, which must always take place whenever a currency, the supply of which is not restricted, becomes degraded or deficient in weight. Previous to the great recoinage in 1773, the quantity of bullion contained in the greater proportion of the gold coins in circulation was reduced nearly 2 per cent. below the mint standard; and, of course, the price of gold bullion, estimated in this degraded currency, rose 2 per cent., or from L.3, 17s. 10½d., its mint price, to L.4. This, however, was too minute a difference to be taken into account in adjusting the ordinary business of buying and selling. And the possessors of coins fresh from the mint, or of coins of full weight, not obtaining more of the general mass of commodities in exchange for them, than they obtained for the lighter coins in circulation, sent the former to the melting pot, and then sold them as bullion. But it is easy to see that this fusion of the coins would have been effectually prevented had they been loaded with a seignorage of 2 per cent. The heavy coins could not then have been melted without losing the additional value given them by the seignorage; and as we have supposed this to have been equal to the excess of the market price of bullion above the mint price, nothing would have been gained by the melters. Had the seignorage been less than the average degradation of the coin, or 2 per cent.,—had it, for example, been only 1 per cent., all those coins whose value was not more than 1 per cent. degraded below their mint standard, might have been advantageously melted; but if the seignorage had exceeded 2 per cent., no

coins whatever could have been melted until the degradation had increased to the same or a greater extent. Money.

This reasoning proceeds throughout on the supposition that the coins on which a seignorage had been charged are not issued in excess. If they were, these consequences would not follow. Their too great multiplication might sink them even below their value as bullion, and occasion their immediate fusion. So long, however, as the State only coins the bullion brought to the mint by individuals, there is no risk of this happening. No one, we may depend upon it, will ever carry bullion to that establishment, and pay the expences of its coinage, unless when the coins are thereby rendered so much more valuable than the unfashioned metal.

Should the Government choose to buy bullion, and coin money on its own account, it might, by a very little attention, easily avoid all over-issue. Suppose the seignorage were 2 per cent., then any given weight of coins of the mint standard ought, provided the currency be not over redundant, to purchase 2 per cent. more than the same weight of bullion. So long, therefore, as this proportion is preserved between coined money and bullion, it shows that the proper supply of currency has been issued. When the relative value of the coins declines below this limit, it shows that too many of them have got into circulation; and when, on the contrary, their relative value increases, it shows that the supply is too limited, and that an additional quantity may be advantageously issued.

But it is easily seen, from the principles we have already established, that it is not at all necessary that the charge for seignorage should be limited to the mere expences of coinage. It may, without injury to any individual, be carried considerably farther. Provided the amount of the coins on which a seignorage is imposed, is limited to the precise amount of those that previously circulated in the country, its imposition to whatever height it might be carried will not affect their exchangeable value. The State being, by the supposition, in the exclusive possession of the privilege of coining, no additional supply of money could be brought to market. And supposing the business of the society to continue the same—that is, supposing the same quantity of commodities to be brought to market, and exchanged for the same quantity of coins of the same denomination, it is plainly impossible that prices could be in any way affected. Invariability of value is the great desideratum in money; and provided this is maintained, as it always may be, by properly limiting the quantity in circulation, it is of no consequence whether the weight of the coins is increased or diminished. A hat that had previously to the imposition of the seignorage sold for a guinea, would still fetch one. The guinea, it is true, would now be diminished in size; but as its value would be increased in proportion to this diminution, and as small coins are equally well adapted to serve every purpose of a circulating medium as those that are larger, the society would not suffer the smallest inconvenience from that circumstance. It is certain, indeed, that if the monopoly were not rigorously enforced, or if individuals were

Money.

permitted to issue supplies of money from private mints, free from the charge of seignorage, the increase of quantity would speedily sink the value of the whole coins in circulation to a level with the expence necessary to indemnify those who could produce them on the lowest terms; so that those on which a high seignorage had been charged, would not have any greater value than those which had been exempted from that charge. But, wherever the supply of money is limited, and competition excluded, this principle ceases to have any operation; and its value is then regulated exclusively by the proportion which the total quantity in circulation bears to the total demand. This principle is farther elucidated in a very able article on seignorage, by Mr Tooke, printed in the *Appendix* (p. 180) to the *Lords' Report* of 1819.

Difficulty of sufficiently limiting the supply of Coins, and consequent necessity of imposing only a moderate Seignorage.

It must not, however, be concealed, that if an attempt were made to charge a very high seignorage, it would be extremely difficult to limit the supply of coins. The inducement to counterfeit money would, in such circumstances, be very greatly increased, while the chances of detection would at the same time be very much diminished. It would not then be necessary, in order to derive a profit from the issue of counterfeit coins, that they should be manufactured of a baser metal. The saving of a heavy charge on account of seignorage would of itself afford a sufficient profit; and this could be derived, though the metal contained in the forged coins was of the standard purity. But, although it might, for this reason, be quite impossible to limit the supply of currency, and consequently to sustain its value, if an exorbitant seignorage were charged, the same difficulty would not stand in the way of the imposition of a moderate one. The nefarious business of counterfeiting could not be carried on if it did not yield a sufficient premium to the forgers to indemnify them for the risks and odium to which they are exposed. Now, it is plain, that if the seignorage were less than this premium, it could afford them no encouragement to the issue of counterfeit coins. And although it might be difficult to form any very precise estimate of what this premium might be, yet it is abundantly certain that it could not amount to less than from 5 to 7 per cent.

Amount of the Gold Coinage since the Accession of James II.

It appears from an account inserted in the appendix to the *Report* drawn up by the Lords in 1819, that new gold coins, of the value of £74,501,586, had been issued by the mint between the 1st January 1760, and the 13th April 1819. To this sum we have to add 5½ millions since issued, making in all an issue of about eighty millions of gold coins since the accession of his late Majesty. But the seignorage was remitted in the reign of Charles II.; and it appears, from the accounts published by Mr Ruding and others, that £28,172,149 of new gold coins were issued in the period between the accession of James II. (1685) and the demise of George II.; so that, in all, upwards of 108 millions of gold coins have been

coined at the expence of the State, and issued since the remission of the seignorage. We shall be considerably within the mark, if we estimate the average annual expence attending this coinage at £12,000,* and on this supposition, it will be found, that the expence of the coinage of gold only has amounted, during the 136 years which have elapsed since the accession of James II., to £1,632,000. But, if a low seignorage of no more than 3 or 4 per cent. had been charged on the gold coins, it would have produced three or four millions—a sum which might have been collected, without occasioning the least injury to any individual, and which, besides defraying the entire expences of the coinage, would have left a considerable surplus revenue.

Money.

In his evidence before the Lords' Committee in 1819, Mr Mushet stated, that, with the improved machinery now in use in the mint, gold coin could be manufactured for about 10s. per cent. (*Minutes of Evidence*, p. 207.) And the expence of the manufacture of the silver coin may, we believe, be taken at about three times as much, or 1½ per cent. In France the coinage of gold costs 0.29 per cent., and of silver 1.50 per cent.: In Russia the gold costs 0.85, and the silver 2.95 per cent. (*Stoich. Tom. VI. p. 74.*)

Expence the Coin of Gold Silver.

The precise period when a seignorage first began to be charged on the English silver coins has not been ascertained. It must, however, have been very early. Mr Ruding mentions, that, in a mint account of the 6th Henry III., one of the earliest he had met with, the profit on £3898, 0s. 4d. of silver coined at Canterbury, is stated to be £97, 9s., being exactly 6d. a-pound, of which the King had £60, 18s. 3½d., and the Bishop the residue. (*Annals of the British Coinage*, Vol. I. p. 179, 4to ed.) In the 28th Edward I. the seignorage amounted to 1s. 2½d. per pound, 5½d. being allowed to the master of the mint, to indemnify him for the expences of coinage, and 9d. to the crown as its profit. Henry VI. increased the master's allowance to 10d. and 1s. 2d., and the King's to 1s. and 2s. In the reign of Edward IV. the seignorage varied from 4s. 6d. to 1s. 6d. It was reduced to 1s. in the reign of Henry VII.; but was prodigiously augmented in the reigns of his successors, Henry VIII. and Edward VI., whose wild and arbitrary measures produced, as we shall afterwards have occasion to show, the greatest derangement in the state of the currency. During the long and glorious reign of Elizabeth, the seignorage varied from 1s. 6d. to 2s. per pound; at which sum it continued, with very little variation, until the 18th of Charles II. (1666), when it was totally remitted.

From this period down to 1817, no seignorage was charged on the silver coin; but a new system was then adopted. The value of silver relatively to gold, having been devaluated in the mint proportion of the two metals fixed in 1718, all the heavy silver coins were withdrawn from circulation, and gold only being used in all the larger payments, it became,

* Lord Liverpool states, that the entire expences of the mint, from 1711 to 1803, amounted to £488,441, which gives an average expenditure of £18,786 a-year. (*Liverpool on Coins*, p. 156.)

Money. in effect, what silver had formerly been, the standard of the currency. The act 56th Geo. III., regulating the late silver coinage, was framed so as not to interfere with this natural arrangement, and to render the new silver coins entirely subsidiary to gold. For this purpose silver is made a legal tender only to the extent of 40s.; and 66s. instead of 62s. are coined out of a pound of troy, the 4s. being retained as a seignorage, which, therefore, amounts to $6\frac{1}{2}\%$ per cent. The power to issue silver is vested exclusively in the hands of Government; who have it, therefore, in their power to avoid throwing too much of it into circulation, and consequently to prevent its fusion, until the market price of silver shall have risen to above 5s. 6d. an ounce.

This arrangement was censured by Lord Lauderdale, Mr J. P. Grant, and others, in the debates on the question of returning to cash payments in 1819. They contended that the overvaluation of silver with respect to gold would render it the interest of every debtor to discharge his debts with silver, and that the gold coins would in consequence be driven from circulation, and exported to other countries. It is plain, however, that this opinion is altogether founded in error. Debtors cannot discharge their debts by silver payments, for, it is only a legal tender to the extent of 40s.; and no creditor could be compelled, or would be disposed to take it in payment of a larger debt, except at its real value. *

In the 18th year of the reign of Edward III., the period when we begin to have authentic accounts of the gold coinage, a pound troy of gold bullion was coined into florins, of the value of L.15: Of this sum only L.13. 16s. 6d. were given to the person who had brought the bullion to the mint to be coined, L.1. 3s. 6d. being retained as seignorage, of which 3s. 6d. went to the Master, and L.1 to the King. But it appears, from the mint indentures, that the seignorage on the coinage of nobles for the same year only amounted to 8s. 4d. And, from this remote period to the accession of the Stuarts, with the exception of the coins issued in the 4th and 5th Edward IV. and the 34th, 36th, and 37th Henry VIII., the total charge of coining a pound weight of gold bullion seldom exceeded 7s. or 8s. money of the time. In the 2d James I., a pound weight of gold bullion was coined into L.40. 10s.; a seignorage of L.1. 10s. being deducted, 6s. 5d. of which went to the Master, and L.1. 3s. 7d. to the Crown. The seignorage on gold was remitted at the same time (18th Charles II.) with the seignorage on silver, and has not since been revived. †

As the regulation of the seignorage depended en-

tirely on the will of the sovereigns, we cannot be surprised at the variations in its amount at different periods, or that it should have fluctuated according to their necessities and caprices. It was, indeed, hardly possible that it should have been otherwise. Our ancestors were totally ignorant of the principle, by a strict adherence to which the imposition of a seignorage can alone be rendered advantageous. They considered it as a tax which might be increased and diminished at pleasure. And, far from taking any steps to limit the quantity of coin in circulation, so as to maintain its value, they frequently granted, to corporate bodies, and even to individuals, ‡ the privilege of issuing coins, not subjected to this charge. No wonder, therefore, that the seignorage should have been considered as a most unjust and oppressive tax, and that its abolition should have been regarded as a very advantageous measure.

Besides the revenue arising from the seignorage, **Remedy or** our kings formerly derived a small revenue from the **Shete.** *remedy or shere.* It having been found impossible to coin money to correspond in every particular, both of weight and purity, with a given standard, a small allowance has always been made, in the different mints, to the master, whose coins are held to be properly executed, provided their imperfections do not exceed this allowance, or remedy. The amount of the remedy has varied very little since the reign of Edward III.; having, during this long period, been almost always one-eighth of a carat, or 30 grains of pure gold per pound of gold bullion, and two penny weight of pure silver per pound of standard silver bullion. By the law of 1815, the remedy for gold coins is fixed at 12 grains per lb. in the weight, and one-sixteenth of a carat in the fineness. The remedy for silver continues the same as before.

It does not appear that our princes derived any considerable advantage from the *remedy* previously to the reign of Elizabeth. But she, by reducing the master's allowance for the expence of coinage from 1s. 2d. to 8d. obliged him to come as near as possible to the *lowest* limit allowed by the remedy. Had the coins been delivered to those who brought bullion to the mint by *weight*, the queen, it is plain, would have gained nothing by this device; but, in the latter part of her reign, and the first seventeen years of that of her successor, James I., they were delivered by *tale*, so that the Crown saved, in this way, whatever additional sum it might otherwise have been necessary to pay to the master, for the expences of coinage. In the great recoinage in the reign of William III., the profit arising from the remedy amounted to no more than 8s. on every hundred

* Those who wish for a farther elucidation of this subject, will do well to have recourse to Mr Mushet's evidence in the *Appendix to the Lords' Report "on the Expediency of the Bank's resuming Cash Payments,"* where it is discussed at great length, and in the most able manner.

† In the tables annexed to this article, the reader will find a detailed account of the amount of the seignorage and its variations in different periods.

‡ Ruding's *Annals of the Coinage*, Vol. I. p. 185. When the right of seignorage was abolished, there was a pension, payable out of the profits derived from it, granted under the great seal, for twenty-one years, to Dame Barbara Villiers, which the legislature ordered to be made good out of the coinage duties imposed by that act. See Ruding, *in loco citato*, and Leake's *Historical Account of English Money*, 2d ed. p. 356.

Money.

pounds weight of bullion; and the coinage is now conducted with so much precision, and the coins issued so near to their just weight, that no revenue is derived from this source.

Seignorage in France.

The continental princes have, we believe, without any exception, charged a seignorage on the coinage of money. In France, this duty had been levied at a very early period. By an ordonnance of Pepin, dated in 755, a pound of silver bullion is ordered to be coined into twenty-two pieces, of which the master of the mint was to retain *one*, and the remaining twenty-one were to be delivered to the merchant who had brought the bullion to the mint. (Le Blanc, p. 87.) There are no means of ascertaining the amount of the charge made by the successors of Pepin, on account of seignorage, until the reign of Saint Louis (1226-1270), who coined the marc of silver into 58 sols, while he only delivered 54 sols, 7 deniers, to the merchant; at this period, therefore, the charge on account of seignorage must have amounted to one-sixteenth of the marc, or to $6\frac{1}{4}$ per cent. The seignorage was subsequently increased or diminished without regard to any fixed principle. In the great recoinage in 1726, it amounted, on the gold coin, to $7\frac{1}{10}$ per cent., and to $5\frac{1}{2}$ per cent. on the silver. In 1729, the mint price, both of gold and silver, were augmented, and the seignorage on the former reduced to $5\frac{1}{10}$ per cent., and on the latter to $4\frac{1}{8}$ per cent. A farther reduction took place in 1755 and 1771, when the seignorage on gold was fixed at $1\frac{1}{3}$ per cent., and on silver at $1\frac{1}{2}$ per cent. At this moment, the seignorage in France hardly covers the expence of coinage, being only about $\frac{1}{3}$ per cent. on gold, and $1\frac{1}{2}$ per cent. on silver.*

SECT. IV.—Expence of a Currency consisting of the Precious Metals.

Estimate of the expence of a Metallic Currency.

The imposition of a moderate seignorage has, however, but a very inconsiderable effect in reducing the expence of a currency consisting of the precious metals. This expence, which is vastly greater than is generally imagined, really consists not in the coinage, for that is comparatively trifling, but in the high value, or, which is the same thing, in the difficulty of the production of the gold and silver of which the coins are manufactured. If, for example, the currency of Great Britain amounted to 50 millions of gold sovereigns, and if the customary rate of profit were 10 per cent., this currency, it is plain, could not cost less than five millions a-year. For, had this 50 millions not been employed as a circulating medium, it would have been invested in branches of industry, in which, besides affording employment to many thousands of individuals, it must have yielded 10 per cent. or five millions a-year, of net profit to its possessors. But this is not the only loss. The capital of 50 millions would not be merely withheld from the great

work of production, and the country deprived of the large revenue it would have derived from its employment, but it would be perpetually diminished. The ordinary tear and wear of the coins is by no means inconsiderable; and supposing the expences of the coinage to be defrayed by a moderate seignorage, the deficiency of the weight of the old worn coins must, when they are called in to be recoinced, be paid by the public. There is, besides, a constant loss from shipwrecks, fire, and other accidents. And, when due allowance is made for these different causes of waste, we do not think that it would be too much to suppose, that a country which had 50 millions of gold coins in circulation, would have annually to import the 50th part of this sum, or *one* million of coins, to maintain its currency at its proper level.

Thus it appears, that if the customary rate of profit in Great Britain were 10 per cent., it would cost us six millions a-year to maintain 50 millions of gold coins in circulation! It is indeed true, that a reduction of the rate of profit would cause a proportionable reduction in the amount of this expence, yet as the reduced expence would still bear the same proportion to the total income of the country that the higher expence did, the real cost of the currency would not be at all diminished. The case of France furnishes a still more striking example of the heavy charges attending the general use of a metallic currency. The total amount of the gold and silver currency of that kingdom has been estimated by Necker at 2200 millions of francs, and by Peuchet at 1850 millions. (*Statistique Elementaire de la France*, p. 473.) Now, supposing the lowest estimate to be the most correct, and taking the rate of profit at only eight per cent., this currency must cost France 148 millions of francs a-year, exclusive of the tear and wear, and loss of the coins, which being taken, as before, at a 50th part of the entire mass, will make the whole annual expence amount to the prodigious sum of 185 millions of francs, or to about seven and a half millions Sterling! This enormous expence certainly forms a very material deduction, from the advantages which have resulted from the use of a currency consisting entirely of the precious metals, and has doubtless been the chief cause why, in an advanced state of society, all civilized and highly commercial countries have endeavoured to fabricate a portion of their money of less valuable materials. Of these substitutes, paper has been by far the most generally resorted to, and is in every respect the most eligible. By using paper instead of gold, we substitute the cheapest in room of the most expensive currency; and enable the society, without loss to any individual, to exchange all the coins which the use of paper money has rendered superfluous, for raw materials, or manufactured goods, by the use of which both its wealth and its enjoyments are in-

Money.

* *Administration des Finances*, &c. par Necker, Tom. III. p. 8.—Dr Smith has stated (Vol. II. p. 335), on the authority of the "*Dictionnaire des Monnoies*, par Abot de Bazinghen," that the seignorage on French silver coins, in 1775, amounted to about 8 per cent. The error of Bazinghen has been particularly pointed out by Garnier, in the Supplemental Volume (p. 234), added to his translation of the *Wealth of Nations*.

Money. creased. Ever since the introduction of bills of exchange, almost all great commercial transactions have been adjusted by means of paper only. It has also been used to a very great extent in carrying on the ordinary business of society. And a plan has recently been suggested, the adoption of which would render it a very easy matter to substitute a paper for a metallic currency, and to keep its value on a par with the value of gold or silver, without making the paper exchangeable for coined money, and, consequently, without requiring the circulation of a single gold or silver coin. This is a very important discovery. *It gives us all the security of gold money, without any portion of its expence*; and the currency of any country in which it was adopted, would certainly approach very near the limits of perfection. The discussion of the principles of this plan is perhaps the most important part of our subject, and will require to be treated at considerable length.*

SECT. V.—*Paper Money.—Principle on which its Value is maintained.*

In the earliest periods of society, subsequent to

the invention of alphabetic characters, the pecuniary engagements of individuals would be reduced to writing. This was necessary to give security to the creditor, that he should be able to claim the full amount of his debts, and to the debtor, that he should not be liable to any overcharge; in a word, to avoid all those differences which never fail to arise where the terms of contracts are not particularly and distinctly specified. But a very short time only could elapse before individuals, who were in possession of written obligations from others, would begin to transfer them to those to whom they were indebted,—and after the advantages derivable from employing them in this way had been ascertained, it was an obvious source of emolument for individuals in whose wealth and discretion the public had confidence to issue their obligations to pay certain sums, in such a form as might fit them, to be easily applied to perform the functions of a circulating medium in the ordinary transactions of life. No one would refuse to accept the promissory note or obligation of an individual of large fortune, and of whose solvency no doubt could be entertained, in payment of any debt that might be due to him. But as full value must have been originally

Money.
Origin of
Paper Mo-
ney, and
principle on
which Bank-
ing is car-
ried on.

* The following estimate of the value of the gold and silver coins, now current in the principal European states, will, we believe, be found to be nearly correct:

Gold and silver coins of Great Britain, as <i>per</i> estimate in next section,	20 millions Sterling.
The value of the gold and silver currency of France has been, as we have just seen, estimated by Peuchet at 1850 millions of francs, or	
The value of the gold and silver currency of Spain was, in 1782, estimated by the Minister of Finance, M. Musquiz (Bourgoing, <i>Modern State of Spain</i> , Vol. II. p. 55. <i>Eng. Trans.</i>), at 80 millions of hard piastres, or	18
The value of the gold and silver money of the Austrian monarchy, in 1807, is estimated by M. Storch (<i>Economie Politique</i> , Tom. VI. p. 80), after Hassel, at only 53½ millions of florins; but so considerable a quantity of the compulsory paper, which had banished the gold and silver money from the country, has since been suppressed, that we may reasonably suppose the value of the coins now current in the Austrian monarchy to be doubled since that period, or to amount at present to 106 millions of florins, or	11
The gold and silver coins of the Prussian monarchy were estimated by Professor Krug (Storch, <i>ubi supra</i>), in 1805, at 60 millions of crowns, or	
And the gold and silver coins of Russia were estimated by M. Storch (<i>id.</i>), in 1815, at 45 millions of roubles, or	-139

We regret we have no means of forming any tolerably correct estimate of the value of the gold and silver currency of Portugal, Italy, Switzerland, Germany, Belgium, Denmark, Sweden, and Turkey in Europe. It is most probable, however, that we shall be within the mark, if we estimate it at two-thirds of the value of the coins in circulation in the other countries, or at 92½ millions, which would give 231½ millions as the value of the aggregate currency of Europe. The expence of this currency, supposing profits to be 10 *per cent.* and one-fiftieth to be annually wasted, would rather exceed 27 millions a-year!

The value of the gold and silver annually dug from the mines of the Old and New World has been estimated (*Bullion Report, Appendix of Accounts*, No. 33) at 45½ millions of dollars, or £10,237,500. We subjoin the general results of this estimation.

	Dollars.
Value of gold and silver annually brought into circulation,	45,762,803
From the Old World,	5,019,408

Money. given for the promissory note, it is clear that while its continuance in circulation could be no loss to the public, it would be a very great source of profit to the issuer. Suppose, for example, that a merchant issues a promissory note for L.10,000, he must, previously to his putting it in circulation, either have received an equivalent sum of ready money, or of some sort of commodities possessed of real value, or, which is the most common case, he must have advanced it to an individual who had given him security for its repayment, with interest. In point of fact, therefore, the issuer has exchanged his *promise to pay* L.10,000 for the profits to be derived from the employment of a real capital of L.10,000; and so long as the promissory note, the intrinsic worth of which cannot well exceed a sixpence, remains in circulation, he will, supposing profits to be 10 per cent., receive from it a revenue of L.1000 a-year. It is on this principle that the business of banking is conducted. A banker could make no profit if he were obliged to keep as much dead stock in his coffers as was equal to the amount of his notes in circulation. But if he is in good credit, a fourth or a fifth part of this sum will perhaps be sufficient; and his profits, after the expences of the establishment, and of the manufacture of his notes, are deducted, will be measured by the *excess* of the profit derived from the notes he has in circulation, over that of the profit he might have realised by the employment of the stock he is obliged to keep in his coffers to meet the demands of the public. "A bank would never be established, if it obtained no other profits but those derived from the employment of its own capital: its real advantage commences only when it employs the capital of others." (*Proposals for an Economical and Secure Currency*, p. 87.)

Limitation
of supply
sufficient to
sustain the
value of
Bank Paper.

As no means have been devised to limit the supply of the promissory notes issued by private individuals, their value, it is plain, could not be maintained if those by whom they were issued fell into discredit, or if they were relieved from their promise to pay them. But it is otherwise with the promissory notes issued by the state, or by an exclusive company acting under its control. The quantity of such notes may be effectually limited; and we have shown that, when this is the case, intrinsic worth is not necessary to a currency, and that, by properly regulating the supply of paper money which has been declared to be a legal tender in all payments, its value may be sustained on a par with the value of gold, or of any other commodity. It was by acting on this principle of limitation, or, which was in effect the same thing, by restricting the issues of the Bank of England, and not from any vague and confused idea that its notes would at some future and indefinite period be paid in gold, that their value was maintained in the interval between the passing of the restriction act in 1797, and the commencement of bullion payments in 1820. No rational or intelligible explanation of this circumstance—a circumstance so much at variance with all the old theories of paper money—can be deduced from any other principle. The circumstance of their being depreciated never creates any indisposition on the part of the public to apply for ac-

commodation to a bank whose notes are a legal tender. The presenter of a bill for discount is quite indifferent whether the notes which are given to him in exchange for it are payable in specie or not. His object, in resorting to the bank, is to exchange his promissory note for money—that is, for paper that will be received in payment of his debts, or of whatever commodities he may be desirous of purchasing. It is, therefore, of no moment to him, whether those who are entrusted with the power of issuing paper, have issued so much as to depress its value relatively to gold, or whether they have restricted their issues so as to sustain its value on a level with the value of that metal. These circumstances, it is true, affect the permanent interest of every class of society, whose incomes cannot be made to vary with every variation in the value of money: but, in as much as the money prices of goods rise and fall with every increase or diminution of the supply of paper, merchants, who are the principal demanders of discounts, are comparatively but little affected by its fluctuations. The merchant who presents a bill for L. 500 or L. 1000 to a bank, has acquired this bill, if it has arisen out of a real commercial transaction, in lieu of a certain quantity of goods, which, at the then value of money, were worth L. 500 or L. 1000; and it is this L. 500 or L. 1000 which, by presenting the bill to the bank, he wishes to obtain. If the value of money had been different, the price of the goods, and consequently the sum for which the bill was drawn, would also have been different. It is to this market value of money at the time that, in all commercial transactions, attention is exclusively paid. When, in 1809, 1810, 1811, 1812, 1813, and 1814, the Bank of England issued such a quantity of paper, as to depress its value from 10 to 25 per cent. below the value of bullion, the circumstance of an act of Parliament having declared, that its notes should be paid in cash at the restoration of peace, had as little effect in raising their value, as their depreciation had in diminishing the applicants for discounts. The truth is, that individuals never resort to a bank for a supply of paper money, unless they have immediate occasion for its services. After it has been obtained, they throw it into the market for whatever it will bring; and as they purchased it on the same terms (for it is seldom that the value of money can be materially affected in the short interval between the time that a bill is discounted and when it becomes due), they generally get as much for it, and perhaps more, than it cost. We shall immediately explain what it is which constitutes the natural limit to the applications for paper money; but we have said enough to show, that it has nothing whatever to do with the convertibility of notes into cash.

Those who have recourse to a bank to obtain discounts of accommodation bills, like the presenters of real bills, consider only the present value of money. Accommodation bills are never discounted, except with the view of immediately employing the money so obtained, either in the purchase of commodities, or of labour, or in the payment of debts: and, whether one pound notes are of the value of 10s. or 20s.

Money. is obviously of no consequence; in as much as the amount of the bill presented for discount is regulated accordingly.

The circumstance of the circulation of country bank notes ceasing as soon as any general suspicion is entertained of the solvency of those by whom they are issued, is nowise inconsistent with this principle. Country bank notes are rendered exchangeable, at the pleasure of the holder, for Bank of England notes; but since the epoch of the restriction down to 1820, the latter not being exchangeable for any other commodity, have constituted the real standard of exchangeable value. When a country bank lost credit, the circulation of its notes was stopped, because a suspicion was entertained that it would be impossible to exchange them for paper of the Bank of England; or, in other words, for that species of paper which constituted the real medium of exchange. But, it is impossible to imagine, that the paper constituting this medium should itself be affected by a want of credit. Every individual knew that it had no intrinsic worth; and, as we have already shown, its value was regulated, and must, whenever it is not rendered exchangeable for a given quantity of some other commodity, continue to be exclusively regulated, by the amount of it in circulation compared with the demand.

It appears, therefore, that if there was perfect security, that the power of issuing paper money would not be abused; that is, if there was perfect security for its being issued in such quantities, as to preserve its value relatively to the mass of circulating commodities nearly equal, the precious metals might be entirely dispensed with, not only as a circulating medium, but also as a standard to which to refer the value of paper.

Unfortunately, however, no such security can be given. This is a point, respecting which there can be no difference of opinion. We have it in our power to appeal to a widely extended and uniform course of experience—to the history of Great Britain, and of every other state in Europe, and to that of the United States—to show that no man, or set of men, have ever been invested with the power of making unrestricted issues of paper money without abusing it; or, which is the same thing, without issuing it in inordinate quantities. If the power of supplying the state with paper money be vested in a private banking company, such as the Bank of England; then, to suppose that they should, by limiting their issues, endeavour constantly to sustain the value of their paper, would be to suppose that they should be extremely attentive to the public interest, and extremely inattentive to their own private interest! The re-enactment of the restriction act, and the rendering of it perpetual, would not have the least effect on the value of our paper currency, provided its quantity was not at the same time increased. But that, in such circumstances, it would be increased, is abundantly certain. Such a measure would enable the Bank of England to exchange bits of engraved paper, not worth perhaps 5s. a quire, for as many, or the value of as many hundreds of thousands of pounds. And is it to be supposed, that the

directors and proprietors of the bank would not avail themselves of such an opportunity to amass wealth and riches? Is it to be supposed, that if the government enables a private gentleman to exchange a bit of paper for an estate, he will be deterred from doing so by any considerations about its effect in sinking the value of the currency of the country? In Loo Choo we might perhaps meet with such a disinterested individual, but if we expect to find him in Europe, we shall assuredly be disappointed. In this quarter of the globe, we are far too eager in the pursuit of fortune to be at all affected by such scruples. It is essential, therefore, that the issuers of paper money should be placed under some check or control; and the comparative steadiness of the value of the precious metals, at once suggests that no check can be so effectual as to subject the issuers of paper money to the obligation of exchanging their notes, at the pleasure of the holder, for a *given and unvarying quantity* either of gold or silver.

But it has been contended, that there is a material difference between paper money issued by a government in payment of the debts it has contracted, and that which is issued by a private banking company in discount of good bills. In regard to the former, it is admitted, on all hands, that it may be issued in excess; but, in regard to the latter, it has been strenuously urged, that "notes issued only in proportion to the demand, in exchange for good and convertible securities, payable at specific periods, cannot occasion any excess in the circulation, or any depreciation." As every one of the arguments advanced by those who contend that the paper currency of Great Britain has not been depreciated since 1797 involve this principle, it will be necessary to examine it a little minutely.

In the *first* place, it may be observed, that the demand for discounts does *not* depend on the nature of the security required for the repayment of the sums advanced by a bank, but on the *rate of interest* for which these sums can be obtained, compared with the ordinary rate of profit which may be made by their employment. If an individual can obtain L. 10,000, L. 100,000, or any greater sum, from a banker, at 4, 5, or 6 per cent., and if he can realise 7, 8, or 10 per cent. by its employment as capital, it is evidently his interest, and it would be the interest of every other person similarly situated, to borrow to an unlimited extent. But a banking company, which was relieved of all obligation to pay its notes in cash, and which, of course, was not obliged to keep any unproductive stock or bullion in its coffers, would be able to issue its notes at the lowest possible rate of interest; and the demand for its paper would, therefore, be proportionably great.

"The interest of money," says Mr Ricardo, "is not regulated by the rate at which the bank will lend, whether it be 5, 4, or 3 per cent., but by the rate of profit which can be made by the employment of capital, and which is totally independent of the quantity or of the value of money. Whether the bank lent one million, ten millions, or a hundred millions, they would not permanently alter the market rate of interest; they would alter only the value of the mo-

Money.

Proposition maintained by those who deny that Bank Paper can be depreciated

Difficulty of limiting the supply of Bank Paper, otherwise rendered by rendering it exchangeable for Gold or Silver

Demand for Discounts depends on a comparison between the rate of Interest and the rate of Profit

Money.

ney which they thus issued. In one case, ten or twenty times more money might be required to carry on the same business than what might be required in the other. The applications to the bank for money, then, depend on the comparison between the rate of profit that may be made by the employment of it, and the rate at which they are willing to lend it. If they charge less than the market rate of interest, there is no amount of money which they might not lend; if they charge more than that rate, none but prodigals and spendthrifts would be found to borrow of them. We accordingly find, that, when the market rate of interest exceeds the rate of 5 per cent., at which the bank uniformly lends, the discount office is besieged with applicants for money; and, on the contrary, when the market rate is even temporarily under 5 per cent., the clerks of that office have no employment." (*Principles of Political Economy*, p. 511.)

From 1809 to 1815 inclusive, the period in which the value of our paper currency relatively to gold was lowest, the market rate of interest considerably exceeded the rate (5 per cent.) at which the Bank of England and most of the country banks invariably lend. Although, therefore, the amount of the paper currency of the country had, in that interval, been very much increased, the applicants for fresh discounts continued as numerous as ever. And there seems no reason to doubt, that, had the directors not been apprehensive, that, ultimately, they might be called upon to pay their notes in specie, the number of them in circulation would have been very much increased; at least, such would most unquestionably have been the case, had the directors acted to the full extent of their avowed opinion, that it was impossible to issue too much paper, or to reduce its value, by engrossing into the circulation such quantities as could be issued in discount of good bills. The wants of commerce are altogether insatiable. Paper money, provided the rate of interest at which bills are discounted is less than the market rate, can never be too abundant. As long as this is the case, million after million may be thrown into the market. The value of the currency may be so reduced as to require a one pound note to purchase a quatern loaf; but the circumstance of its value being diminished in proportion to the increase of its quantity, would render the demand for additional supplies as great as ever.

If the Bank of England were alone in the possession of an alchemical process, whereby guineas could be manufactured with the same facility as notes, it could not be disputed that it would then be in the power of the bank to depreciate the former value of gold, by issues of what had been produced at so very little cost. Now, in what respect would this fictitious case differ from the actual situation of the Bank of England, if the restrictive act were rendered per-

Money.

petual? The bank would then be enabled, without check or control, to exchange its paper for landed property, manufactured goods, government securities, &c. But we have shown, that the value of this paper, like the value of gold, in the hypothetical case, would depend entirely on the proportion which the supply bore to the demand; and, as the demand is not affected by an increase of quantity,—for that increase, by diminishing its value, renders the larger quantity of as little efficacy as the smaller quantity was before,—it is abundantly clear, that if the bank lent at a sufficiently low rate of interest, there could be no limit to its issues.

In the second place, if it were true, which most certainly it is not, that the notes of a private banking company, issued in discount of good mercantile paper, could not be depreciated from excess, that will not apply to the case of the Bank of England; for, the greater part of its paper is issued in payment of the interest of the national debt, amounting to about thirty-two millions a-year, exclusive of the sinking fund!—and really, when such is the fact, it was a little too much to contend, as the apologists of the restriction act have almost always done, that Bank of England paper could not be depreciated; because it was only issued in discount of legitimate mercantile paper, payable sixty days after date! *

On the whole, therefore, it is plain, that whether the power of issuing paper money be vested in the hands of a private banking company, or of the government, it must be placed under some efficient check or control, such as the obligation to pay their notes in gold or silver. It is easy to discover the manner in which a check of this kind would limit the issue of paper, and sustain its value. Whenever the bank had issued so much paper as to sink its value relatively to bullion, its notes would be returned upon it, to have them exchanged for a higher value; and the bank would, in consequence, be obliged, in order to prevent the exhaustion of its coffers, to contract its issues, and thus to raise its paper to a level with gold. An extremely small profit, or an extremely small depreciation of paper, as compared with gold or silver, would be sufficient to induce the holders of bank paper to send it to be exchanged for those metals; and, hence, the value of bank notes convertible at pleasure into a given and unvarying quantity of gold or silver, can never differ considerably from its value. The issues of the Bank of England were for more than a century limited by the very principle, and in the very manner we have now explained, and during that whole period, they were hardly ever depreciated $\frac{1}{4}$ per cent., and never more than 2 per cent., and that but for a few days only.

But, although it is thus imperatively necessary, in

* Mr Baring must be excepted from this remark, for, in a debate on the 1st of May 1816, he distinctly stated in his place in the House of Commons, "that the great mass of the bank paper was issued compulsorily in payment of the public creditor, and in the other great transactions of government."

tem.

order to avoid all sudden and injurious fluctuations in the value of money, that paper money should be made exchangeable for gold or silver, it does not follow that it should be made exchangeable for gold or silver coins. A currency would be in its most perfect state, if it consisted wholly of paper money; but of paper money of equal value with gold or silver. It is impossible, however, to attain to this degree of perfection, so long as paper is made convertible into coin. Such convertibility renders the paper money of the same value as metallic money; but it is defective, inasmuch as it does not banish the latter from circulation, and does not, therefore, save the whole of the heavy expence of a metallic currency. The proximity of the period (7th May 1821), when the Bank of England recommenced paying in coins, has not afforded time for engrossing any considerable quantity of them into circulation. But, in 1819, Mr Baring stated, before a Committee of the House of Commons, that it was his opinion, that, in the event of the Bank of England paying their notes, at the pleasure of the holder, in a good and perfect coin, such as the sovereign, all the one pound notes would be driven from circulation, and that from 40 to 45 millions of sovereigns would ultimately be absorbed into the circulation.* But, notwithstanding the deference due to Mr Baring's authority, we have no hesitation in thinking, with the Committee, that this estimate is much too high. In corroboration of this remark, we may observe, that Messrs Whitmore (*Appendix, Bullion Report*, p. 121, 8vo ed.) and Harman (*Commons' Report*, 1819, Mi-

Money.
notes of Evidence, p. 40), late Governors of the Bank of England, join in estimating the amount of the gold coins in circulation, during the three years previous to 1797, at 20 millions; and although this estimate is probably rather underrated, there are good grounds for concluding, that it is the most accurate of any that have hitherto been framed, and that it has come as near the truth as it is perhaps possible to attain in such matters.† But, whatever may have been the amount of the gold coin in circulation in 1797, there does not seem to be any good reason whatever for supposing that more of it will now be demanded: On the contrary, the extraordinary increase in the number of country banks, and the almost exclusive use of paper money for the last twenty years, must evidently form very considerable obstacles to the reintroduction of the former amount of metallic money. But, on the reasonable hypothesis, that 20 millions of coin were in circulation in 1797, and that an equal quantity will now be required for that purpose, it is plain the rendering of Bank of England notes exchangeable for coin cannot cost less than two millions a year! For the interest of a capital of 20 millions, including a moderate allowance for the tear and wear of the coins, would, at least, amount to 10 per cent.: And if Ireland were taken into account, the total annual cost of rendering the notes of the two great Banks exchangeable for coined money, could not be estimated at less than from two and a half to three millions.

It is in vain to contend, that the greater part of this loss must fall on the banks, and that, there-

* *Report on the Resumption of Cash Payments by the Bank, Minutes of Evidence*, p. 182.

† There was coined in the period of the great recoinage, from 1773 to 1777, both inclusive, of gold, L. 19,591,833
Remained in circulation of old guineas, of heavy and light weight, not brought in, about (Chalmers, *Comparative Estimate*, p. 350) 2,000,000
There was coined in the period from 1778 to 1796, both inclusive, of gold L. 28,863,437
But Mr Rose states (*Brief Examination*, App. No. 1), that very near one-half of the gold, coined from 1778 to 1798, was procured from melted light guineas, &c. and therefore deducting 14,000,000

There remains sum to be added to the currency, from 1778 to 1796, both inclusive, 14,863,437
L. 36,455,260

Now, supposing six millions of gold coin to have been locked up in the coffers of the Bank of England, of the country banks, and of individuals, in 1796, and estimating at other ten millions the quantity of guineas exported by the Government and individuals during a period of twenty years, including the greater part of the American war, and the three first years of the late war, which, considering that no seignorage is charged on the gold coin of this country, and that, therefore, it might, when melted down, be exported without any loss, is surely not a very exaggerated allowance, it results that Mr Whitmore's and Mr Harman's estimate may be justly considered as coming pretty near the truth. Had the estimate been 25 instead of 20 millions, it would, we think, have been as much above the mark, as it is now probably below it.

Mr Chalmers (*Comparative Estimate*, p. 349) estimated the aggregate amount of the gold and silver coins in circulation, in 1786, at 24 millions. Mr Rose (*Brief Examination*, App. No. 4) estimated the amount of the gold coins in circulation, in 1799, at 44 millions; and, in 1805, Lord Liverpool supposed there were 30 millions of guineas in circulation. (*Treatise on Coin*, p. 177.) It is quite unnecessary to enter into any argument, to show the gross and palpable exaggeration of the two last estimates. The author of an able critique on Lord Liverpool's work, in the 7th volume of the *Edinburgh Review*, says, "We have no desire to hazard a computation on a subject, where the data are necessarily so imperfect; but, rather than call the quantity of gold now in circulation thirty millions, we should be disposed to deny that it can possibly amount to one million!"

fore, its only effect will be to lessen the profit of these establishments. The wealth of the state is made up of the wealth of individuals; and if the bank proprietors were not obliged to employ twenty or thirty millions, or the value of twenty or thirty millions, in the purchase of gold, they would employ it in some other manner,—in the cotton or woollen manufacture, in the construction of docks, warehouses, &c. or in such a way as would be productive of wealth to themselves, and consequently to the community. It cannot be denied that the wealth of the bank proprietors is essentially national wealth; and as whatever has a tendency to increase their fortunes, without diminishing those of others, must be advantageous, the circumstance of the expence of providing a gold currency falling principally on them, ought not to be held as a valid reason for declining to adopt any expedient for diminishing that expence. Besides it is not true, that the expence of providing a gold currency would fall entirely on the bank proprietors. As the law now stands, the whole expence of coinage, amounting to about £. 15,000 a year, is paid by the state; and although a seignorage were charged to cover this expence, still, when it becomes necessary to call in the coins in circulation, the difference between the value of the old money brought to the mint to be recoinced, and the coins of full weight which are given in exchange for them, has to be made up by the public.

We may, therefore, conclude, that, by continuing to act on the system now established, and obliging the Bank of England, and the Bank of Ireland, to exchange their notes for coined money, it will be necessary for these establishments to purchase and issue from twenty to thirty millions worth of gold coins. And the loss attending the abstraction of so great a sum from the productive industry of the country, added to the expence of mintage, and the loss that must be occasioned by the decay of the coins, ought certainly to induce us to adopt any other system, which, at the same time that it affords us equal security against fluctuations in the value of paper money, by constantly keeping it on a par with gold, would save all this expence.

Expl
of M. R.
Ricardo's Plan
for making
Bank Notes
payable in
Bars of Bul-
lion,

To Mr Ricardo we are indebted for the discovery of such a system. This able Economist has shown how paper money may be kept constantly on a par with gold, without requiring the circulation of a single gold coin. His contrivance for accomplishing this desirable object is equally admirable for its simplicity and effect. It consists in making bank-notes exchangeable for bars of assayed bullion of the standard purity, at the mint price of £. 3, 17s. 10½d. an ounce; or, which is the same thing, Mr Ricardo proposes, that for every sum of £. 3, 17s. 10½d. of paper presented to the bank for payment, it should be obliged to give, not three guineas and 14s. 10½d., but an ounce of standard gold bullion.

"To secure," says Mr Ricardo, "the public against any other variations in the value of the cur-

rency than those to which the standard itself is subject, and, at the same time, to carry on the circulation with a medium the least expensive, is to attain the most perfect state to which a currency can be brought; and we should possess all those advantages by subjecting the bank to the delivery of uncoined gold or silver at the mint standard and price, in exchange for their notes, instead of the delivery of guineas; by which means paper would never fall below the value of bullion, without being followed by a restriction of its quantity. To prevent the rise of paper above the value of bullion, the bank should be also obliged to give their paper in exchange for standard gold at the price of £. 3, 17s. * an ounce. Not to give too much trouble to the bank, the quantity of gold to be demanded in exchange for paper at the mint price of £. 3, 17s. 10½d., or the quantity to be sold to the bank at £. 3, 17s., should never be less than 20 ounces. In other words, the bank should be obliged to purchase any quantity of gold that was offered to them, not less than 20 ounces, at £. 3, 17s. an ounce, and to sell any quantity that might be demanded, at £. 3, 17s. 10½d. While they have the power of regulating the quantity of their paper, there is no possible inconvenience that could result to them from such a regulation.

"The most perfect liberty should be given, at the same time, to export or import any description of bullion. These transactions in bullion would be very few in number, if the bank regulated their loans and issues of paper by the criterion which I have so often mentioned, namely, the price of standard bullion, without attending to the absolute quantity of paper in circulation.

"The object which I have in view would be in a great measure attained, if the bank were obliged to deliver uncoined bullion in exchange for their notes at the mint price and standard; though they were not under the necessity of purchasing any quantity of bullion offered them at the prices to be fixed; for that regulation is merely suggested to prevent the value of money from varying from the value of bullion, more than the trifling difference between the prices at which the bank would buy and sell, and which would be a near approximation to that uniformity in its value which is acknowledged to be so desirable." (*Proposals for an Economical and Secure Currency*, p. 25.)

This original and well-digested scheme was first brought under the notice of the public in 1816; and its adoption as a temporary measure, to facilitate the return to payments in coin, was recommended, in 1819, by the committees of the Legislature appointed to inquire into "The Expediency of the Bank's resuming Cash Payments." In conformity with this recommendation, a bill was brought into Parliament by Mr Peel, which enacted, that, on the 1st February 1820, the Bank of England should be bound to deliver gold bullion, properly stamped and assayed, in bars of not less than 60 ounces each, in

* "The price of £. 3, 17s., here mentioned, is, of course, an arbitrary price. It might be fixed either a little higher or a little lower. In naming £. 3, 17s., I wish only to elucidate the principle."

Money. exchange for a proportionate number of its notes, when demanded, at the rate of L. 4, 1s. *per* ounce; that, on the 1st October 1820, they should be bound to deliver bullion in a similar manner, at L. 3, 19s. 6d. *per* ounce; that, on the 1st May 1821, they should be bound to deliver bullion for notes at L. 3, 17s. 10½d. *per* ounce, being the standard mint price; and that this system should continue for two years more, when payments in coin were to be resumed. This last part of the arrangement has not, however, been permitted to take effect; an act having been passed last session (1820-21), enabling the bank instantly to resume cash payments of its one and two pound notes, which it has resolved to withdraw entirely from circulation; and it has since been stated by the Governor of the Bank, that the directors have commenced paying their other notes in coin, and that they are anxious to facilitate the employment of a large quantity of specie as money.*

Advantages of Mr Ricardo's Plan. In practice Mr Ricardo's plan worked extremely well; while the over issue of paper was effectually prevented, only a very few bars were demanded from the bank, and it was generally supposed, that, instead of its operation being thus prematurely checked, it would have been rendered perpetual, and the farther circulation of gold coins prevented. Even as a device for preserving paper on a par with gold, it was, in some material respects, obviously preferable to the old method of exchanging notes for coins. When a currency consists partly of paper, and partly of the precious metals, any over issue of the former depresses, not merely the value of the paper money, but of the coins which circulate along with it. These coins are, therefore, immediately converted into bullion. Bullion, however, cannot be accumulated in any one country, without losing its relative value; and hence the ultimate effect of an over issue of bank paper, in a country whose currency partly consists of coins, is an exportation either of coin or of bullion formed out of the coin. But, on Mr Ricardo's system, as there could be no coin in circulation, there could be no employment for the melters, and no loss thereby occasioned to the state. As soon as the bullion merchants found that a profit might be made by sending notes to the bank to be exchanged for bullion, they would do so; and as the exportation of bullion is now perfectly free, it would, like sugar or coffee, be sent abroad, whenever it was more valuable there, and less valuable here, than any other commodity; that is, whenever its exportation was sure to be advantageous.

As the maintaining of paper on a par with gold, at the least possible expence to the country, and with the least inconvenience to all parties concerned, is the great object to be effected by Mr Ricardo's plan, there does not seem to be any good reason why the bank should have been obliged to give so small a quantity as sixty ounces of bullion, as fixed by the act of 1819, in exchange for a proportionable quantity of their paper. Should the plan be

Money. again adopted, it would save a great deal of trouble, or at least obviate a great deal of cavilling, were the *minimum* quantity of bullion, which could be demanded from the bank, fixed at 500 or 1000 ounces; and as, according to the plan in question, the value of paper would be prevented from falling below, or rising above, the value of gold, by the operations of respectable bullion merchants, a class of men remarkable for their shrewdness, and generally possessed of large capitals, this regulation, while it would be productive of benefit to the bank, would not, in a public point of view, be attended with any ill effects.

Though it certainly is against the interest of the directors of the bank, to reduce their paper below its proper level, still it cannot be denied, even by those who contend that they have no power indefinitely to add to their issues, that they have the power to *refuse to discount*, and that, consequently, they have it in their power to reduce the currency to the narrowest limits. Such a power ought not to be entrusted to the state itself, and still less to the managers of a private banking company; for there can be no security for uniformity in the value of the currency, when its augmentation or diminution depends solely on the will of the issuers. But, under the operation of Mr Ricardo's system, the bank would not only be prevented from reducing the value of its notes below the value of bullion, but it would also be prevented from raising them above its value. Should the directors capriciously limit the quantity of its paper, they would raise its value; and bullion would forthwith be carried to the bank, and exchanged for notes, at the rate of L. 3, 17s., or of L. 3, 17s. 6d. an ounce. The *minimum* quantity of bullion to be offered to the bank in exchange for its paper, ought also, in order to save trouble, to be limited to 500 or 1000 ounces. And, as it is the interest of the bank to furnish the circulation with such a quantity of paper as would keep its value from rising above the value of bullion, it could not complain of being subjected to a restraint which would never be felt except when its issues had been improperly reduced.

With a paper currency convertible into bullion the bank would, in a great measure, be secured against the ill effects of any sudden panic amongst the holders of its notes. Panics generally operate with the greatest effect on the lower classes, or on the holders of small notes; and it is they that, on such occasions, press to the bank to demand payment. Extensive merchants and money-dealers are aware that no bank, however wealthy, could retire all its notes in the short space of eight or ten days; and they are also aware that the maintenance of their own credit is intimately connected with the prosperity of the bank. But such considerations do not influence the holders of small notes; and accordingly we find that the drain upon the bank, in 1782, and the crisis of 1797, were chiefly brought about by the prevalence of a panic among the retail traders and small farmers. But, to such persons, a bar of gold

Money.

could be of very little service; and, even if it were, by fixing the *minimum* quantity of bullion to be given by the bank in exchange for its notes at 500 or 1000 ounces, it would not be possible for them to make any sudden run. Before sending notes to be exchanged, they would have to concert measures, to join together, and to make a demand in common. A considerable time being thus necessarily expended in the adjustment of the preliminary steps of the business, the bank would be enabled to make the necessary preparations to meet the run; and, what is of still more consequence, since the panic could not operate immediately, it is probable, that, by the time preparations had been made for demanding payment from the bank, it might have altogether subsided. This certainly forms a very strong recommendation of the plan in question; and it is one which was not originally in the contemplation of Mr Ricardo.

By lessening the danger to be apprehended from sudden runs, and by preventing all demand for bullion, for the purpose of internal circulation, except as small change, this plan would enable the bank to carry on business with a comparatively small supply of bullion in its coffers. In ordinary cases, indeed, no bullion would ever be demanded, except when the directors had fairly overstepped the proper limit in issuing; and the country would not only be benefited by the profitable employment of the capital, which would otherwise be invested in coin, but it would also be benefited by the profitable employment of the greater part of that capital, which, previously to the restriction, was locked up in the coffers of the bank.

The circumstance of no alteration being required in the law relating to country banks, is also a considerable recommendation in favour of Mr Ricardo's plan. It would be enough that these should then, as now, be required to pay their notes, when demanded, in Bank of England notes, or in the legal currency of the country. If the value of the latter is sustained, it is impossible that the interchangible paper of the country banks can ever be depreciated from over issue.

It appears, therefore, as well from reasoning as from experience, that, by the adoption of this plan of making notes payable in bullion, we should have all the security against fluctuation in the value of the currency that we possess under our present system; while we should possess this security, without incurring any part of the expence of a gold or silver currency; except what might be required for small payments below the value of *one pound*, thereby effecting a saving, which, on account of the united kingdom, cannot be estimated at less than *two and a half or three millions a year*. And it further appears, that the security of the bank against the per-

nicious effects of sudden panics among the holders of its notes would be greatly increased by its adoption, and that the banking business might henceforth be carried on with a much less amount of unproductive capital.

The unprecedented and alarming increase of the crime of forgery,—a crime which was scarcely known in this country previously to the restriction act,*—and the general belief that it could not be prevented otherwise than by the suppression of the smaller notes of the Bank of England, appears to have been the sole reason why a plan, which promised to be productive of so many advantages, has been abandoned, and the country again subjected to the heavy expence of a metallic currency; nor, provided this had really been the only means by which so desirable an object as the prevention of forgery could be effected, should this sacrifice have been deemed too great. We are satisfied, however, that such is not the case; and that it is not to the increased issue of Bank of England notes, but to their shamefully defective execution, that the prevalence of forgery ought principally to be ascribed. It is now nearly twenty-five years since Bank of England paper has constituted the legal currency of the country, and during the whole of that period, and for many years previously, there has been *no visible improvement in its manufacture*. Apparently satisfied with the security derived from *private marks*, the directors have continued to issue notes, engraved in so wretched a style, and which afford so few distinguishing peculiarities, or points, on which the eye can rest when comparing them with each other, that they almost seem to have been intended to stimulate the efforts of forgers! But, although no improvement has been made for nearly half a century in the manufacture of the notes of the Bank of England; and although they are executed in so rude and clumsy a manner, as to be easily imitated by every engraver's apprentice, it would be rather rash to conclude from thence that the arts have all the while been stationary, and that it is impossible to render their imitation a work of comparative difficulty! It is, we admit, no easy task to manufacture a note which may not be counterfeited, even by ordinary engravers, with sufficient exactness to deceive the mass of those into whose hands it might be supposed to come in the course of circulation. But, that this is not an insurmountable difficulty is certain. The experience, both of Ireland and the United States, shows that notes may be engraved in such a manner, as to exclude all dangerous competition on the part of forgers. Previously to 1814, the period when the Directors of the Bank of Ireland adopted Mr Oldham's plan for engraving their notes, their forgery was carried on to a very great extent. But, since then, it has almost entirely ceased; and it appears from a paper printed last session (1821), by

Money.

Its supposed tendency to perpetuate the Crime of Forgery; reason why Mr Ricardo's Plan has been abandoned.

Increase of Forgery shown to be a consequence of the defective execution of Bank of England Notes.

* It appears, from returns made to an order of the House of Commons, that, in the *eight years* previous to the restriction, *no individual was capitally convicted of forgery*, while, in the succeeding *eight years*, *one hundred and forty six individuals were capitally convicted and executed*! Only four prosecutions for forgery were instituted by the Bank of England from 1783 to 1797: In the equal period, from 1797 to 1811, they instituted 469 prosecutions! And this frightful progression has since increased even more rapidly.

Money.

order of the House of Commons, that only *seventeen* persons had been convicted of issuing forged notes in Ireland in the *three years* ending with 1820. "In Dublin, where forgeries prevailed to the greatest extent, they have been for a long time comparatively banished. It may indeed be affirmed that there are no forged notes in circulation. Occasionally attempts are made to issue them, but they are immediately detected. Scarcely a single forged note has, during the last three years, found its way to the bank."* The improvement of the engraving of the American notes has had precisely the same effects. Although, therefore, we do not pretend to be acquainted with the nature of the obstacles which have hitherto prevented the Directors of the Bank of England from issuing the improved notes, of which so much has been said, there are certainly very strong reasons for doubting whether they can be so formidable as has been represented. It is a very mistaken notion to suppose, as the Directors of the Bank of England seem to have done, that nothing less than the issue of *inimitable* notes can be of any real service. This is a degree of perfection to which it is in vain to expect to attain. Whatever has been executed by one set of artists, may be imitated by some other set. But, provided this imitation be rendered, as it may be, a work of very great difficulty, the public interests will be sufficiently protected. Notes, which can only be counterfeited by the best engraver, will very rarely be counterfeited at all, and never in such numbers as to be productive of any seriously injurious consequences. First rate talent is seldom, or never, found among forgers. It is by the inferior class of artists that the practice of counterfeiting has been principally carried on. Artists of superior genius, and of superior skill in their profession, have higher objects in view; and only a very small proportion of those who have the prospect of rising to distinction, by the fair and honourable exercise of their talents, will be found profligate enough to prostitute them for the sake of defrauding their fellow citizens. But, not to insist on this point, it is plain that what *has been done* in Dublin and New York, may be done in London. And although the Directors of the Bank of England cannot justly be blamed for not having produced inimitable notes; it is not easy to see how they can be vindicated from the charge of culpable negligence, and inattention to the interests of the public, in having persisted for so long a period, and after so many improvements had been effected, in issuing notes executed in so slovenly a manner, as really to act as a species of premium on forgery.

But, even if it could be shown that the suppression of the smaller Bank of England notes was the only way by which an effectual check could be given to the crime of forgery, it may be fairly doubted, whether this advantage would not be more than compensated by the increased facilities that would, in

Money.

consequence, be given to the issuers of base coins. Forgery, it must be remembered, is an evil inseparable from the use of money—an abatement from the innumerable advantages of which it has been productive. Whatever commodity may be adopted as a circulating medium, it must, in the nature of things, be a hopeless task to attempt completely to guard against the efforts of the issuers of spurious money. If the currency consists of paper, it will be counterfeited, and if it consists of the precious metals, they will be adulterated and debased.† All that can be done, is to throw obstacles in the way of forgery—to render it, if possible, a work of extreme difficulty; and there is no good reason for supposing that it would be more difficult to do this with notes than with coins. Indeed, the very contrary seems to be established. No scheme for the improvement of the coinage has had the same success in preventing the issue of spurious coins, that Mr Oldham's inventions have had in preventing the issue of forged notes. In reasoning on this subject, we have been led into error by referring exclusively to the paper of the Bank of England. But the difficulties opposed to the issue of forged paper must be estimated by the success which forgers have had in imitating the *best*, and not the *worst*, notes in circulation. And if we refer to this proper criterion—if, for example, we take the improved notes of the Bank of Ireland, instead of the *unimproved* notes of the Bank of England, as a standard, it will be found that the security of the public against fraud and imposition is any thing but impaired by the issue of paper.

We do not, therefore, think that the plea of its being necessary to the prevention of forgery, forms any valid reason for the adoption of the measure now in progress for withdrawing the smaller notes of the Bank of England, and reverting to specie payments. To counterfeit a guinea is as great a crime as to counterfeit a guinea note; and the withdrawing of one species of money, without taking any steps to guard against the forgery of that by which it is to be supplied, merely gives a different, and, perhaps, a more profitable direction to the perverse ingenuity of those who exist only by the plunder of the public. The prevention of forgery might have been better accomplished by obliging the Bank of England to improve the fabric of its notes. And had this been done, the country would have saved an unprofitable and useless expenditure of *two millions and a half, or three millions a-year*.

Should the plan for sustaining the value of paper money, suggested by Mr Ricardo, be again adopted, it would be expedient that steps should be taken for enabling the public to participate in the profits made by the Bank of England. In a general point of view, it is, indeed, of no importance whether the paper declared by Government to be a legal tender, and made exchangeable for bullion, is issued by the State, or on account of a private bank-

Williams *On the Increase of Forgery on the Bank of England, &c.*, p. 83.

† Notwithstanding the diminution of coined money during the restriction, the convictions for false coining increased from 380 in the seven years preceding 1797, to 558 in the seven years following that epoch.

Money. ing company. In either case, the country will be benefited by the substitution of a cheap for an expensive species of money, and its productive capital will be increased by the whole amount of the sums that would otherwise have been employed in the effecting of exchanges. But although the national wealth would be equally increased, whether the power to issue paper were placed in the hands of the Government or of a private company, it is plain the wealth of individuals would be very differently affected by each of these measures. By declaring Bank of England notes to be a legal tender, and by obliging the Bank to give bars of bullion to those only who made a demand for L.1000 or L.2000, it is nearly certain that the Bank would be able to keep 25 millions of notes afloat with not more than one or two millions of bullion in its coffers as dead stock. But supposing that the stock of bullion amounted to five millions, and deducting this sum from the Bank's issues, there would remain a sum of 20 millions, which, supposing them to be lent at 5 per cent., the rate at which the Bank uniformly lend, would yield one million a-year. And if, from this sum, we deduct the expences of the establishment, which, on the highest estimate, cannot be taken at more than L.150,000 a-year, there would remain a clear surplus profit of L. 850,000 a-year. Now, admitting that this immense sum might be as profitably and as prudently expended by the bank proprietors as it could be by any other class of individuals, yet there can be no possible reason why the government should gratuitously concede to any private company privileges calculated to enable them to realise such prodigious gains. In any circumstances, such a proceeding would evince a very culpable inattention to the interests of the public, and, in the present financial situation of the country, would be a degree of wanton and unjustifiable profusion which could not be tolerated. If, therefore, Mr Ricardo's plan were to be carried into effect, the public ought, undoubtedly, to be permitted to share in the profits of the bank. And, besides the advantages to be derived from the adoption of the plan in disengaging a large capital from a comparatively unproductive employment, it would have the additional advantage of yielding a considerable revenue—L. 500,000 a-year perhaps—to the public treasury.

Necessity of a Legislative Enactment to prevent the Circulation of Country Bank-Notes of a Lower Value than the Notes of the Bank of England. Whether, however, the measure now in progress for withdrawing the smaller notes of the Bank of England, and supplying their place with gold coins, should be persevered in, or whether the plan which we have endeavoured to elucidate and explain should be adopted in its stead, it appears to be equally necessary to prohibit the issue of local notes of a less value than the lowest notes issued by the Bank of England. Uniformity of value, and security against sudden and dangerous fluctuations, are the great requisites in a currency; and they can never be more than imperfectly attained, while the country banks are permitted to issue notes of a lower value than the metropolitan bank. It is true, that, so long as the obligation to give gold coin or Bank of England notes in exchange for country notes is enforced, the latter cannot be permanently, nor even for any considerable period, depreciated from over issue. The

circulation of depreciated country notes is not, however, the danger that ought to be chiefly guarded against. The great risk incurred by the holders of such notes does not consist so much in the chance of their value falling two, three, four, &c. per cent. below the value of the standard, as in the chance of their losing their value altogether, and becoming perfectly worthless.

From the principle on which the banking business is conducted, that is, from the circumstance of the profits of a banking company depending mainly on the excess of the value of their notes in circulation above the value of the dead stock retained in their coffers to meet the demands of the public, it is obvious, that no company, however wealthy, and however well their affairs may be managed, can avoid being considerably distressed and embarrassed by sudden runs, or demands for payment of their notes. But panics, which are the great cause of runs, seldom or never become general, except when the banks issue notes of so low a value as to fit them for being used in retail trade, and in the ordinary business of society. Previously to 1797, neither the Bank of England, nor any of the English country banks, were permitted to issue notes for less than five pounds. The currency used in small payments was thus made to consist exclusively of the precious metals; and as there was no opportunity for a panic taking place among the holders of small notes, only very few runs were made on the banks, and very little loss was sustained by their failure. In 1797 this system was changed, The Bank of England was then, for the first time, empowered to issue one and two pound notes, a privilege which was soon after granted to the country banks. Bank paper having, in consequence of this arrangement, and of the restriction on cash payments, become the only currency of the country, and being in the hands of almost every individual, the chances of runs, and, what is more to the purpose, runs themselves, were multiplied to an unprecedented extent. Every subsequent period of considerable commercial distress has been marked by the ruin of several country banks; and in some districts these establishments have been almost entirely swept away, and the inhabitants involved in a degree of misery and suffering of which no adequate idea could have been previously formed.

From an account in the *Appendix to the Lords' Report*, "On the Resumption of Cash Payments by the Bank," it appears, that, in the period from 1797 to 1818, 230 commissions of bankruptcy had been issued against country bankers in England and Wales. Of these the far greater proportion were issued in 1814, 1815, and 1816. In 1814, 29 banks failed, out of 699 that were then in existence; in 1815, 26 failed out of 543; and, in 1816, 37 out of 585: so that, in the short space of three years, NINETY-TWO country banks, or one out of every seven and a half of the total number of these establishments, existing in 1814, became bankrupt, besides a much greater number that stopped payment, for a longer or shorter period. Nor did the mischief cease here. The currency was not only diminished by the sudden withdrawing of the notes of the insolvent banks, but the issues of all

Failure of the Country Banks in 1811, 15, and 16.

Money. the rest were very greatly contracted. The Board of Agriculture estimated, that, in the county of Lincoln only, above three millions of country bank paper had, in the course of eighteen months, been withdrawn from circulation. And, in a variety of other extensive districts in England, and in the south of Ireland, no money was to be found in circulation,—credit was totally annihilated; and so great was the panic, that even the notes of the Bank of England would hardly pass current, except at a discount. These failures were the more distressing and calamitous, as they chiefly affected the industrious classes, and frequently swallowed up in an instant the fruits of a long life of unremitting and laborious exertion. That support, on which too many of the agriculturists and manufacturers rested, gave way at the moment when it was most necessary. Prices instantly fell; and thousands, who, but a moment before, considered themselves affluent, found they were destitute of all real property, and sunk, as if by enchantment, and without any fault of their own, into the abyss of poverty. The late Mr Horner, the accuracy and extent of whose information on such subjects cannot be called in question, stated, in his place in the House of Commons, that the destruction of English country bank paper in 1814 and 1815 had given rise to a universality of wretchedness and misery, which had never been equalled, except, perhaps, by the breaking up of the Mississippi scheme in France!*

It is certain, however, that if the country banks are still permitted to continue their issue of small notes, their liability to runs will, in future, be very much increased. From 1797, down to last year, the notes of the Bank of England, for which the country notes were made exchangeable, were not convertible into gold or silver; and those who then made a run on a country bank merely got one species of paper in exchange for another. It is obvious, that this circumstance must have operated in a very powerful manner, to diminish the tendency among the poorer classes to runs. But, now that

the Bank of England has ceased issuing small notes, and begun paying its large notes in cash, the country bankers will be obliged to give cash for their small notes; and there can be no doubt, that, in all periods of difficulty and alarm, many who would never have thought of making a demand on them for Bank of England notes, will be disposed to make such a demand for coins.

In order to diminish the chances of runs arising from the new position in which the country banks are now placed, the directors of several of these establishments have adopted the ingenious device of making their notes payable in London, and not in the place where they are issued! This is a good deal similar to the clause that was formerly inserted in the notes issued by some of the Scots banks, which made it optional for them either to pay the bearer when the note was presented, or six months after such presentment, allowing legal interest for these six months. The effects of this clause, which was abolished by act of Parliament, in degrading the value of the Scots notes, are detailed by Dr Smith; and there can be no question that the clause inserted in the English notes will have similar effects. A note, which cannot be converted into cash, unless it is carried two or three hundred miles, perhaps, from the sphere of its circulation, is plainly not so valuable as a note payable at the place where it is issued; and if the Legislature do not interfere to check this practice, we shall certainly have as many different values of paper, as there are different distances between the principal country towns and London! An abuse of this kind cannot be tolerated.

It appears, therefore, that, to give uniformity to the value of the currency, and as far as possible to guard the public against the risk of sudden and injurious fluctuations in the value of money, the circulation of all local notes, for a smaller sum than the lowest notes issued by the Bank of England, should be prohibited. It is in vain to urge the respectability and the wealth of the individuals engaged in the banking business, in opposition to this regulation.

* The number of country banks in England and Wales, to which licences had been granted to issue promissory notes, in 1797, is not exactly known. They are stated by Mr Thornton, in his *Essay on Paper Credit* (p. 154), to have amounted to 350; but other accounts reduce this number to 230.—(*Appendix Bullion Report*, p. 213, 8vo. ed.) They have since been prodigiously multiplied. We subjoin an account of their number, of the number of their partners, and of the number of the commissions of bankruptcy issued against them from 1808 to 1818, both inclusive.—(See *Appendix Lords' Report*, 1819, pp. 416, 426.)

Years.	Number of Banks.	Number of Partners.	Commissions of Bankruptcy.	Years.	Number of Banks.	Number of Partners.	Commissions of Bankruptcy.
1808	755	2,255	5	1814	699	2,145	29

1813	733	2,234	8				

There were thirty banking companies in Scotland, in 1818, possessed of licences to issue promissory notes; which, in addition to their head offices, had ninety-eight subordinate offices, or agencies, in different parts of the country.

Money.

This consideration might have been equally urged previously to the failures in 1814, 1815, and 1816; and, as we have already shown, no bank can be secure against runs, and consequently against embarrassments, if it issues notes of a low value. Neither can it be justly objected that this measure would interfere with the freedom of industry. It is admitted on all hands, that, in order to prevent the confusion that would arise from the currency of coins of different values, but of the same denomination, it is expedient the government should interfere to prohibit the circulation of private tokens, and of all coins which are not struck at the public mint, and which are not of a certain weight and purity. But, if this regulation be expedient, why should it not also be expedient to set limits to the values for which bank-notes shall be issued? The issue of low notes, by private banking companies, has, both in this country and in America, been productive of the greatest mischiefs; and the government is not only warranted, but it is their duty, and they are called upon to adopt such regulations as may be necessary to prevent a repetition of the calamities we have so lately experienced. Women, mechanics, and labourers of all descriptions—persons who are nowise qualified to judge of the comparative stability of banking companies, are all dealers in money; and they have a right to expect protection from such an obvious cause of loss as the granting of permission to every individual to undertake, without restraint or limitation of any kind, to supply the currency destined to carry on the ordinary business of the country.

If Mr Ricardo's plan were adopted, and bank-notes made exchangeable for bullion, and not for coins, it would be still more desirable that all country notes for less than five pounds should be prohibited, and their place exclusively supplied with Bank of England small notes. This would greatly diminish the chances of runs on the country banks; while it would, at the same time, give a uniformity of value, and a degree of cheapness and security, to the currency, to which it is, we apprehend, almost visionary to expect that it should otherwise attain.

As a farther means of increasing the respectability, and of adding to the stability of the country banks, the act of 1708, prohibiting more than six persons from entering into any association, or copartnery, for carrying on the trade of private bankers in England and Wales, ought to be repealed. It is, indeed, astonishing how so oppressive and so absurd a regulation should have been so long permitted to disgrace the Statute Book. We are inclined to think, that the superior wealth and solidity of the Scots banks, is in no inconsiderable degree owing to their being exempted from the operation of this regulation.

SECT. V.—*Whether Gold or Silver ought to be adopted as the Standard of the Currency, or whether it ought to consist of both.*

As the value of gold and silver, or the cost of their production, is perpetually varying, not only relatively to other commodities, but also relatively to each other, it is impossible arbitrarily to fix their relative value. Gold may now, or at any given period, be to

silver as 14 or 15 is to 1; but were guineas and shillings coined in that proportion, the discovery of either a gold or silver mine of more than the ordinary degree of productiveness, or the discovery of any abridged process, by which labour might be saved in the production of one of the metals, would derange this proportion. As soon, however, as the mint proportion between the different metals ceases to be the same with that which they bear to each other in the market, then it becomes the obvious interest of every debtor to pay his debts in the metal whose mint valuation is highest.

In 1718, in pursuance of the advice of Sir Isaac Newton, the value of the guinea was reduced from twenty-one shillings and sixpence to twenty-one shillings; the value of fine gold to fine silver being then rated, in our mint, at 15 $\frac{3}{4}$ to 1. But, notwithstanding this reduction, the guinea was still rated at a higher value, compared with silver, than it ought to have been. This over-valuation is estimated, by the late Lord Liverpool, to have been, at the time, equal to fourpence on the guinea, or to 1 $\frac{1}{4}$ per cent.; and, as the real value of silver relatively to gold continued to increase during the greater part of last century, this difference, which, even in the reign of George I., caused all considerable payments to be made in gold, became afterwards much greater. This error in the mint valuation of silver and gold was the cause that, during the long period from 1718 down to the late recoinage, no silver currency, of the legal weight and fineness, would remain in circulation. The real value of silver coins, relatively to gold coins, which were, equally with the former, made a legal tender by the proclamation of 1718, being underrated, they were no sooner issued than they found their way to the melting-pot. None, therefore, but very light coins remained in circulation; and when, in 1797, the further coinage of silver was forbidden, the silver currency was very much debased. But, as this currency existed only in a *limited quantity*, it did not, according to the principle already explained, sink in its current value. Though so debased, it was still the interest of debtors to pay in the gold coin. If, indeed, the quantity of this debased silver coin had been very great, or if the mint had issued such debased pieces, it might have been the interest of debtors to pay in this debased money. But its quantity being limited, it sustained its value; and gold, therefore, was in practice the real standard of the currency.

The act of 1774, declaring that silver should not be a legal tender for any debt exceeding £25, *unless by weight according to the mint standard*, had not, as has been supposed, any effect in causing the general employment of gold as money, in preference to silver. For, to use the words of Mr Ricardo, "this law did not prevent any debtor from paying any debt, however large its amount, in silver currency fresh from the mint. That the debtor did not pay in this metal was not a matter of chance, nor a matter of compulsion, but wholly the effect of choice. It did not suit him to take silver to the mint, but it did suit him to take gold hither. It is probable that if the quantity of this debased silver in circulation had been enormously great, and also a legal tender, that

Money.

valuation of Gold at the Mint the case of its being used in all considerable Payments in this Country.

Impossibility of arbitrarily fixing the relative Value of Gold and Silver.

Money.

a guinea would have been, as in the reign of William III., worth 30 shillings; but it would have been the debased shilling that had fallen in value, and not the guinea that had risen." (*Principles of Political Economy*, &c. p. 520.)

Contrary effect produced by the over-valuation of Silver in the market.

In France a different valuation of the precious metals has had a different effect. The louis d'or which, previously to the recoinage in 1785, was rated in the mint valuation at 24 livres, was really worth 25 liv. 10 sols. Those, therefore, who chose to discharge the obligations they had contracted, by payments of gold coin in preference to silver, plainly lost 1 liv. 10 sols on every sum of 24 livres! The consequence was, that very few such payments were made, that gold was almost entirely banished from circulation, and that the currency of France consisted almost exclusively of silver. (Say, *Tom. I.* p. 393.) In 1785, a sixteenth part was deducted from the weight of the louis d'or, and since that period the proportional value of the precious metals, as fixed in the French mint, has more nearly corresponded with the proportion they bear to each other in the market. Indeed, Mr Baring stated, in his evidence before the Committee of the House of Commons in 1819 (*Report*, p. 192), that the difference between the mint and market proportions of gold and silver at Paris in 1817 and 1818, had not exceeded from one-tenth to one-fourth *per cent.* There is, however, no reason to presume that this coincidence, which must have been in a great degree accidental, can be maintained under any arbitrary system. To ensure the indifferent use of gold and silver coins in countries where they are both a legal tender, their mint proportion would require to be every now and then adjusted, so as to correspond with their real proportion. But as this would obviously be productive of much trouble and inconvenience, the preferable plan undoubtedly is to make only one of the metals a legal tender, and to allow the relative worth of the other to be adjusted by the unrestricted competition of the sellers and the buyers.

The absurdity of employing equally two metals as a legal tender for debts, or as a standard of value, was unanswerably demonstrated by Mr Locke and Mr Harris, and has been noticed by every subsequent writer; but so slow is the progress of improvement, that it was not till 1816 that it was enacted that gold only should be a legal tender for any sum exceeding 40s.

Silver preferable to Gold as a Standard.

Whether, however, gold should have been adopted as the standard of exchangeable value, in preference to silver, is a question which is not so easy of solution, and on which there is a great diversity of opinion. Mr Locke, Mr Harris, and Mr Ricardo, are decidedly of opinion that silver is much better fitted than gold for a standard; while Dr Smith, although he has not expressed himself explicitly on the subject, appears to think that gold ought to be adopted in preference; and this opinion has been very ably supported by the late Lord Liverpool, in his valuable work *On the Coins of the Realm*.

It would be presumption in us to attempt to decide on a matter of this kind, respecting which the ablest political economists differ thus widely. We are inclined, however, to concur in opinion with those

who think silver ought to be adopted as the standard. Whatever metal is set apart for this purpose, it will be a very difficult task to preserve the currency from falling into a deranged state, if it be not used in small as well as in large payments.

Money.

"The *integer*," says Mr Harris, "and its several parts, should bear an exact and due proportion of value to each other; and this would be impossible, if they were made of different materials. There must be coins of about the value of shillings and sixpences; and it would be better if we had some that were still smaller. Those sort of coins are the most frequently wanted, and there is no doing without them. But a coin of a shilling, or even of half a crown value, would be too small in gold; and, therefore, at present gold is much too valuable for a standard of money. And it would be a ridiculous and vain attempt to make a standard *integer* of gold whose parts should be of silver; or to make a motley standard, part gold and part silver."—(*Harris On Coins*, Part I. p. 60.)

Silver is, besides, as steady in its value as gold. Almost all foreign countries have adopted it as their standard; and the demand and supply is comparatively regular. The use of paper, as the principal circulating medium, entirely removes the great objection against silver—its being too bulky to be advantageously used in large payments.

Whether gold or silver be adopted as the standard of our currency, will not affect its total cost or value; for, the quantity of metal employed as money, or the quantity of metal for which paper is the substitute, must always be in an inverse proportion to the value or cost of that metal. If gold be continued as the standard, fourteen or fifteen times less of that metal than of silver will be required; or, what is the same thing, if the denomination of a pound were given to any *specific weight* of gold or silver, fifteen times more of such silver pounds would be required to serve as currency, or as bullion to exchange for notes—fifteen to one being about the proportion which gold bears in value to silver; and hence the expence of a currency consisting of gold coins, or of silver coins, is the same; and the expence is also the same whether the currency consists of paper convertible into gold bullion or silver bullion. But, as gold is too valuable, in proportion to its bulk, to be coined into pieces of the value of a shilling or a sixpence, and as it is desirable to have the subsidiary currency necessary in small payments, formed of the same metal as the principal currency, or as the bullion for which paper is made exchangeable, silver ought, in preference, to be adopted as the standard.

If Mr Ricardo's plan should be again adopted, and if it should be deemed inexpedient to change the standard, it would not be proper to make any alteration on the late act, allowing a seignorage of 6 *per cent.* on the silver coin; for, without some very great change in the present comparative value of gold and silver, the imposition of this seignorage will prevent all risk of the fusion or exportation of the subsidiary currency. Neither, on the supposition that silver were to be assumed as the standard, could there be any valid objection against continuing the seignorage. For, as notes would be exchangeable for bul-

A Gold and Silver Currency equally valuable.

Money.

lion, and not for coin, it would not cause any reduction of the standard, while it would have the beneficial effect of preventing the too great multiplication of the subsidiary currency, and of relieving the country of the expences of coinage.

Were a seignorage charged on the gold coins, paper, it is obvious, might be depreciated to the full extent of that seignorage, before it would be the interest of the holders to demand coin for the purpose of melting it into bullion, and consequently before the check of specie payments could begin to operate. But, even with such a seignorage, the risk of paper being depreciated, might be completely avoided, by making it obligatory on the bank to pay their notes, either in bullion, at the mint price of L.3, 17s. 10½d. an ounce, or coin, at the pleasure of the holder. A regulation of this kind could not be justly considered as imposing any hardship on the bank; for it is plain, that no bullion would ever be demanded from it, except when, by the issue of too much paper, its value had been sunk below the standard.

SECT. VI.—Standard of Money.—Degradation of the Standard in Italy, France, Great Britain, and other Countries.—Pernicious Effects of this Degradation.

Standard of Money.

By the standard of money is meant the degree of the purity or fineness of the metal contained in the coins of a particular country, and the quantity or weight of such metal contained in these coins. Twelve ounces of the metal, of which standard English silver coins are made, contains 11 ounces 2 dwts. fine, and 18 dwts. alloy; and of a pound Troy of this standard silver, our money pound, called the pound Sterling, contains 66 shillings, or $\frac{8}{9}$ parts of $\frac{1}{2}$ of a pound Troy of fine silver, that is, 1614 $\frac{8}{9}$ grains. From the 43d of Elizabeth down to 1816, when the act 56th Geo. III. cap. 68, imposing a seignorage of about 6 per cent. on the silver coin, was passed, the pound weight of standard silver bullion had been coined into 62 shillings. All the English silver coins have been coined out of silver of 11 oz. 2 dwts. fine, from the Conquest to this moment, except for a short period of sixteen years, from 34th Henry VIII. to the 2d Elizabeth.

Purity of English Coins.

The purity of gold is not estimated in Great Britain, and in most other European countries, by the weights commonly in use, but by an Abyssinian weight, called a *carat*. The carats are subdivided into four parts, called grains, and these again into quarters; so that a *carat grain*, with respect to the common divisions of a pound Troy, is equivalent to 2½ penny-weights. Gold of the highest degree of fineness, or pure, is said to be 24 carats fine. When gold coins were first made at the English mint, the standard of the gold put in them was of 23 carats 3½ grains fine, and $\frac{1}{4}$ grain of alloy; and so it continued, without any variation, to the 18th Henry VIII.,

Money.

who in that year first introduced a new standard of gold of 22 carats fine, and 2 carats alloy. The first of these standards was called the old standard; the second was called the new standard, or crown gold, because crowns, or pieces of the value of five shillings, were first coined of this new standard. Henry VIII. made his gold coins of both these standards under different denominations; and this practice was continued by his successors until 1633. From that period to the present, the gold of which the coins of this kingdom have been made has been invariably of the new standard, or crown gold; though some of the coins made of the old standard previously to 1633 continued to circulate till 1792, when they were forbidden to be any longer current. (Liverpool *On Coins*, p. 27.)

Weight of English Coins.

The standard of our present gold coins is, therefore, 11 parts of fine gold, and 1 part of alloy. The pound Troy of such standard gold is divided into 44½ guineas, each of which ought, consequently, when fresh from the mint, to weigh $\frac{1}{44\frac{1}{2}}$ of 12 ounces, or 5

dwts. 9 $\frac{8}{9}$ grains. The sovereign, or twenty shilling piece, weighs 5 dwts. 3 $\frac{7}{8}$ grains of standard gold, or 4 dwts. 17 $\frac{1}{16}$ grains of pure gold.

The alloy in coins is reckoned of no value. It is allowed, in order to save the trouble and expence that would be incurred in refining the metals, so as to bring them to the highest degree of purity; and because, when its quantity is small, it has a tendency to render the coins harder, and less liable to be worn or rubbed. If the quantity of alloy were considerable, it would lessen the splendour and the ductility of the precious metals, and would add too much to the weight of the coins.

Having thus ascertained what the standard of money really is, we shall now proceed to examine the effects produced by variations in the standard. This is, both in a practical and historical point of view, a very important inquiry.

Variations of the Standard and General Remarks

To make any direct alteration in the terms of the contracts entered into between individuals, would be a degree of barefaced oppression, and of wanton and tyrannical interference with the rights of property, that could not be tolerated. Those, therefore, who have hitherto endeavoured to enrich one part of society, at the expence of another, have found it necessary to act with greater caution and reserve. They have been obliged to substitute artifice for open and avowed injustice. Instead of directly altering the stipulations in contracts, they have ingeniously bethought themselves of altering the standard, by a reference to which these stipulations had been adjusted! They have not said, in so many words, that 10 or 20 per cent. should be added to or deducted from the mutual debts and obligations of society, but they have really effected the same thing, by making a proportional change in the value of the currency. Men, in their bargains,

* The carat is a bean, the fruit of an Abyssinian tree, called Kuara. This bean, from the time of its being gathered, varies very little in its weight, and seems to have been, in the earliest ages, a weight for gold in Africa. In India it is used as a weight for diamonds, &c. Bruce's *Travels*, Vol. V. p. 66.

Money. do not, as we have already shown, stipulate for *signs* or *measures of value*, but for real equivalents. Money is not merely the standard by a comparison with which the relative value of commodities is ascertained at any given period; but it is also the equivalent by the delivery of a fixed amount of which, the stipulations in almost all contracts and engagements may be discharged. It is plain, therefore, that no variation can take place in its value, without essentially affecting all these stipulations. Every addition to the value of money must make a corresponding addition to the debts of the state, and of every individual; and every diminution of its value must make a corresponding diminution of these debts. Suppose that, owing to an increased difficulty of production, or to the increase of the quantity of bullion contained in coins of the same denomination, the value of money is raised 20 per cent., it is plain that 20 per cent. is, in consequence, added to all the various sums in which one part of society is indebted to the other part. Though the nominal rent of the farmer, for example, is not increased by this means, his real rent is increased: He continues to pay the same number of pounds or livres as formerly; but the pound or the livre is become more valuable, and requires the sacrifice of *one-fifth* part more of corn, of labour, or of any other commodity whose value has remained stationary, to obtain them. On the other hand, had the value of money fallen 20 per cent., the advantage, it is plain, would have been all on the side of the farmer, who would have been entitled to claim a discharge from his landlord, when he had paid him only *four-fifths* of the rent he had really bargained for.

But, notwithstanding it is thus obviously necessary, in order to prevent the pernicious subversion of private fortunes, and the falsifying of all precedent contracts, that the standard of money, when once fixed, should be religiously kept sacred, there is nothing that has been so frequently changed. We do not here allude to those variations which affect the value of the material of which the standard itself is composed, and against which it is impossible to guard, but to the changes which have been made in the quantity of that material contained in the same nominal sum of money. In almost every country, debtors have been enriched at the expence of their creditors. The necessities, or the extravagance of governments, have forced them to borrow; and to relieve themselves of the incumbrances they had contracted, they have almost universally had recourse to the disgraceful expedient of degrading the coin; that is, of *cheating* those who had lent them money to the extent of the degradation, and of enabling every other debtor in their dominions to do the same.

The ignorance of the public in remote ages facilitated this species of fraud. Had the names of the coins been changed when the quantity of metal contained in them was diminished, there would have been no room for misapprehension. But, although the weight of the coins was undergoing perpetual, and their purity occasional reductions, their ancient denominations were almost uniformly preserved; and the people who saw the same names still remaining after the substance was diminished,—who saw coins

of a certain weight and fineness circulate under the names of florins, livres, and pounds, and who saw them continue to circulate as such, after both their weight and the degree of their fineness had been lessened, began to think that they derived their value more from the *stamp* affixed to them, by authority of government, than from the quantity of the precious metals they contained. This was long a very prevalent opinion. But the rise of prices which invariably followed every reduction of the standard, and the derangement that was thereby occasioned in every pecuniary transaction, undeceived the public, and taught them, though it has not yet taught their rulers, the expediency of preserving the standard of money inviolate.

Before proceeding to notice the changes made in the currency of this and other countries, it may be proper to observe, that the standard is generally debased in one or other of the undermentioned ways.

1st, By simply altering the *denominations* of the coins, without making any alteration in their weight or purity. Thus, suppose sixpence, or as much silver as there is in sixpence, should be called a shilling, then a shilling would be two shillings, and twenty of these shillings, or ten of our present shillings, would constitute a pound sterling. This would be a reduction of 50 per cent. in the standard.

2d, The standard may be reduced, by continuing to issue coins of the same weight, but making them baser, or with less pure metal and more alloy.

3d, It may be reduced, by making the coins of the same degree of purity, but of diminished weight, or with less pure metal: or it may be reduced partly by one of these methods, and partly by another.

The first of these methods of degrading the standard was recommended by Mr Lowndes in 1695, and if injustice is to be done, it is certainly, on the whole, the least mischievous mode by which it can be perpetrated. It saves all the trouble and expence of a recoinage; but as it renders the fraud too obvious, it has been but seldom resorted to. In inquiries of this kind, however, it is rarely necessary to investigate the manner in which the standard has been degraded. And by its reduction or degradation, we uniformly mean, unless when the contrary is distinctly expressed, a diminution of the quantity of pure metal contained in coins of the same denomination, without regard to the particular mode in which such diminution may have been effected.

In conformity with what we have observed in the first section of this article, relative to the universality of the ancient practice of weighing the precious metals in every exchange, it is found that the coins of almost every country have the same names as the weights commonly used in them. To these weights the coins at first exactly corresponded. Thus the *talent* was a weight used in the earliest periods by the Greeks, the *as* or *pondo* by the Romans, the *livre* by the French, and the *pound* by the English and the Scotch, &c.; and the coins originally in use in Greece, Italy, France, and England, received the same denominations, and weighed precisely a talent, a pondo, a livre, and a pound. The standard has not,

Money.

Manner of changing the Standard.

Money. however, been preserved inviolate, either in ancient or modern times. But the limits within which an article of this kind must be confined, prevents us from tracing the various changes in the money of this and other countries, with the minuteness which the importance of the subject deserves, and obliges us to notice only those that were most prominent.*

History of
the Money
of Rome.

ROMAN MONEY.—We learn from Pliny, that the first Roman coinage took place in the reign of Servius Tullus, that is, according to the common chronology, about 550 years before Christ. The *as* or *pondo*, of this early period, contained a Roman pound of copper, the metal then exclusively used in the Roman coinage, and was divided into twelve parts or *uncie*. If we may rely on Pliny, this simple and natural system was maintained until 250 years before our era, or until the first Punic war, when the revenues of the state being insufficient, the government attempted to supply the deficiency, by reducing the weight of the *as* from 12 to 2 ounces! But it is extremely improbable, that a government, which had maintained its standard inviolate for 300 years, should have commenced the work of degradation, by at once reducing their standard to a sixth part of its former amount; and it is equally improbable that so sudden and excessive a reduction could have been made in the value of the current money of the state, and, consequently, in the debts due by one individual to another, without occasioning the most violent commotions. Nothing, however, is said in any ancient writer, to entitle us to infer that such commotions actually took place, and we, therefore, concur with those who think that the weight of the *as* had been previously reduced, and that its diminution, which, it is most probable, would be gradual and progressive, had merely been carried to the extent mentioned by Pliny during the first Punic war. In the second Punic war, or 215 years before Christ, a further degradation took place, and the weight of the *as* was reduced from two ounces to one ounce. And by the Papyrian law, supposed to have passed when Papyrius Turdus was Tribune of the people, or 175 years before Christ, the weight of the

Weight of
the *As*.

as was reduced to half an ounce, or to $\frac{1}{2}$ of its ancient weight, at which it continued till Pliny's time and long after.†

The denarius, the principal silver coin in use among the Romans, for a period of 600 years, was coined five years before the first Punic war, and was, as its name imports, rated in the mint valuation at 10 asses. Mr Greaves, whose dissertation on the denarius has been deservedly eulogised by Gibbon (*Decline and Fall*, Vol. III. p. 89), shows that the denarius weighed at first only one-seventh of a Roman ounce, ‡ which, if Pliny's account of the period when the weight of the *as* was first reduced was correct, would give the value of silver to copper in the Roman mint as 840 to 1, which Mr Greaves very truly calls a "most unadvised proportion." But if we suppose, with Mr Pinkerton (*Essay on Medals*, Vol. I. p. 132, edit. 1789), that when the denarius was first issued, the *as* only weighed 3 ounces, the proportion of silver to copper would be as 252 to 1;—a proportion which, when the *as* was soon after reduced to 2 ounces, would be as 168 to 1, or about a third more than in the British mint. When, in the second Punic war, the *as* was reduced from 2 ounces to 1, the denarius was rated at 16 asses.

Money.
Proportion
of Silver to
Copper.

During his stay in Italy, Mr Greaves weighed many of the consular denarii, that is, as he explains himself, of the denarii that were struck after the second Punic war, and previously to the government of the Cæsars, and he found, by frequent and exact trials, the best and most perfect of them to weigh 62 grains English Troy weight. (Greaves' *Works*, Vol. I. p. 262.) Now, as the English shilling (new coinage) contains very nearly 87½ grains standard silver, this would give 8½d. for the value of the consular denarius. We should, however, fall into the grossest mistakes, if we indiscriminately converted the sums mentioned in the Latin authors by this or any other fixed proportion. It is not enough to enable us to judge of the real value of a coin, that we know its weight; we must also know the degree of its purity, or the fineness of the metal of which it is made. But Mr Greaves did not assay any of the denarii weighed

Value of the
Denarius.

* It is impossible for us to enter in this place into any discussion relative to the value of the Grecian money. It is, however, a subject of no little interest and curiosity. M. Rome de l'Isle, in his *Traité de Metrologie*, published in 1789, has given an account of the weight, and of the degree of fineness of an immense number of attic *drachmas* and *tetradrachmas*. But he does not seem to have been more fortunate than his predecessors, in deducing the value of the *talent* from the weight of the *drachmas*. The errors and absurdities into which modern critics and commentators have fallen, in estimating the value of the sums mentioned in ancient authors, is indeed astonishing. They are ably pointed out in a short essay, *De la Monnaie des Peuples Anciens*, in the supplemental volume added by Ganner to his translation of the *Wealth of Nations*.

† "Servius rex primus signavit æs. Antea rudi usos Romæ Remeus tradit. Signatum est nota pecudum unde et pecunia appellata. * Argentum signatum est anno urbis DLXXXV. Q. Fabio Cos. quinque annos ante primum bellum Punicum. Et placuit denarius pro X. libris æris, quinarium pro quinque, sestertium pro dipondio ac semisse. † Æris autem pondus æris imminutum bello Punico primo cum impensis resp. non sufficeret, constitutumque ut asses sextentario pondere ferirentur. Ita quinque partes factæ lucra, dissolutumque æs alienum. ** Postea, Annibale urgente, Q. Fabio Maximo Dictatore, asses unciales facti: placuitque denarium XVI. assibus permutari, quinarium octonis, sestertium quaternis. Ita resp. dimidium lucrata est. Mox lege Papyria semunciales asses facti."—(Plinii, *Hist. Nat. Lib. 33*, cap. 3. Ed. Lugd. Bat. 1669.)

‡ This is indeed decisively proved by a passage in Celsus. "Sed et antea sciri volo in uncia pondus denariorum esse septem" (Cels. Lib. 18, cap. 17.)

Money. by him. And although it were true, as most probably it is, that, from the first coinage of silver in the 465th year of the city to the reign of Augustus, the weight of the denarius had remained constant at $\frac{1}{4}$ th of a Roman ounce, or about 62 grains; and that, from the reign of Augustus to that of Vespasian, it only declined in weight from $\frac{1}{4}$ th to $\frac{1}{8}$ th of an ounce;* still it is abundantly certain that its real value had been reduced to a much greater extent. Of this fact the authority of Pliny is decisive; for he expressly states, that Livius Drusus, who was Tribune of the people in the 662d year of the city, or 177 years after the first coinage of silver, debased its purity, by alloying it with $\frac{1}{4}$ th part of copper. (Lib. 33, cap. 3, previously quoted.) And in a subsequent chapter (the 9th) of the same book, he informs us that Anthony the Triumvir mixed iron with the silver of the denarius; and that, to counteract these abuses, a law was afterwards made providing for the assay of the denarii. Some idea of the extent to which the debasement of the purity of the coins had been carried, and of the disorder which had in consequence been occasioned, may be formed from the circumstance, also mentioned by Pliny, of statues being every where erected in honour of Marius Gratidianus, by whom the law for the assay had been proposed! But this law was not long respected; and many imperial denarii are now in existence, consisting of mere plated copper. (Bazingham, *Dictionnaire de Monnoies*, Tom. II. p. 64.)

on Aureus. Gold was first coined at Rome 62 years after silver, in the 517th year of the city, and 204 years before Christ. The aureus originally weighed $\frac{1}{6}$ th part of the *pondo* or Roman pound; but by successive reductions its weight was reduced, in the reign of Constantine, to only $\frac{1}{12}$ d part of a pound. The purity, however, as well as the weight of the aureus was diminished. Under Alexander Severus it was alloyed with $\frac{1}{4}$ th of silver. We learn from Dion Cassius, who was contemporary with Severus, that the aureus was rated at 25 denarii; a proportion which Mr Pinkerton thinks was always maintained under the Emperors. (*Essay on Medals*, Vol. I. p. 148.)

Value Sester-. The want of attention to this progressive degradation has led the translators of, and commentators on, ancient writers, to the most extraordinary conclu-

sions. The sesterlius, or money unit of the Romans, was precisely the fourth part of a denarius. *Nostri autem*, says Vitruvius, lib. 3. cap. 1, *primo decem fecerunt antiquum numerum, et in denario denos æreos asses constituerunt, et ea re compositio nummi ad hodiernum diem denarii, nomen retinet; etiamque quartam ejus partem, quod efficiebatur ex duobus assibus et tertio semisse SESTERTIUM nominaverunt.* When, therefore, the denarius was worth 8 $\frac{1}{2}$ d., the sesterse must have been worth 2 $\frac{1}{4}$ d. But the sesterse being thus plainly a multiple of, and bearing a fixed and determined proportion to the denarius, and consequently to the as, the aureus, and the other coins generally in use, it must have partaken of all their fluctuations. When they were reduced, the sesterse must have been reduced likewise; for if it had not been so reduced, or, which in effect is the same thing, if it had been necessary to increase the quantity of the degraded denarii and aurei contained in a given sum of sestertii in proportion to their degradation, nothing, it is obvious, could have been gained by falsifying the standard. But as we know that on one occasion the republic got rid of one-half of its debts—*respublica dimidium lucrata est*—by simply reducing the standard of the as, it is certain that the value of the sesterse must have fallen in the same proportion, just as in England we should reduce the pound sterling, our money unit, by reducing the shillings of which it is made up.†

But, although it had not been possible to produce such clear and explicit testimony to show the continued degradation of the Roman money, the obvious absurdity of many of the calculations which have been framed, on the supposition of its remaining stationary at the rates fixed in the earlier ages of the commonwealth, would have sufficiently established the fact of its degradation. Dr Arbuthnot's *Tables of Ancient Coins*, which, for nearly a century, have been considered in England, and in the greater part of the Continent, as of the highest authority, are constructed on the hypothesis that the denarii weighed by Mr Greaves were of equal purity with English standard silver, and that no subsequent diminution had been made either in their weight or fineness! The conclusions derived from such data are precisely of the same sort we should arrive at, if, in estimating

Errors of Dr Arbuthnot and others.

* Greaves, Vol. I. p. 331. Gibbon's *Miscellaneous Works*, Vol. V. p. 71.

† All the writers on ancient coins, with the single exception of Mr Pinkerton, agree in supposing the sesterse to have been originally, and to have always continued to be, a silver coin. Mr Pinkerton has, however, denied this opinion, and on the authority of the following passage of Pliny, contends that the sesterse was at the time when Pliny wrote, whatever it might have been before, a brass coin. "*Summa gloria aris nunc in Marianum conversa, quod et Cordubense dicitur. Hoc a Liviano cadmiam maxime scribet, et orichalci bonitatem imitatur in SESTERIIS, DUPONDIIARIISQUE, Cyprio suo ASSIBUS contentis.*" (Lib. 31, cap. 2.) That is, literally, "The greatest glory of brass is now due to the Marian, also called that of Cordova. This, after the Livian, absorbs the greatest quantity of lapis calaminari, and imitates the goodness of orichalcum (yellow brass) in our SESTERII and DUPONDIIARI, the ASSES being contented with the Cyprian (brass)." (Pliny had previously observed, that the Cyprian was the least valuable brass.) This passage is, we think, decisive in favour of Mr Pinkerton's hypothesis. But, in the absence of positive testimony, the small value of the sesterse might be relied on as a sufficient proof that it could not be silver. When the denarius weighed 62 grains, the sesterse must have weighed 15 $\frac{1}{2}$, and been worth 2 $\frac{1}{4}$ d.; but a coin of so small a size as to be scarcely equal to one-third of one of our sixpences, would have been extremely apt to have been lost; and could not have been struck by the rude methods used in the Roman mint with any thing approaching to even tolerable precision. It is, therefore, much more reasonable to suppose that it was of brass.

Money.

the value of a French livre previously to the Revolution, we took for granted that it weighed a pound of pure silver, as in the reign of Charlemagne. Among many other things even more extraordinary, we learn from Arbuthnot, that Julius Cæsar, when he set out for Spain, after his praetorship, was just L.2,018,229 Sterling worse than nothing,—that Augustus received, in legacies from his friends, L.32,291,666,—that the estate of Pallas, a freedman of Crassus, was worth L.2,421,875, and, which is still better, that he received L.121,093 as a reward for his virtues and frugality,—that Æsop, the tragedian, had a dish served up at his table which cost L.4,843,—that Vitellius spent L.7,265,625 in twelve months in eating and drinking,—and that Vespasian, at his accession to the empire, declared, that an annual revenue of L.322,916,666 would be necessary to keep the state machine in motion! It is astonishing, that none of our scholars or commentators seem ever to have been struck with the palpable extravagance of such conclusions—conclusions which, to use the words of Garnier, “ont mis l’histoire Ancienne, sous le rapport des valeurs, au même degré de vraisemblance que les contes de *Mille et une Nuits*!” They have, we believe, without any exception, slavishly copied the errors of Arbuthnot; and to this hour the computations in the works on Roman antiquities used in our most celebrated schools and universities, are all borrowed from his work! It ought to be remembered, that the value of gold and silver must, because of the greater poverty of the mines of the old world, and the comparatively small progress made by the ancients in the art of mining, have been much greater in antiquity than at present. But, without taking this circumstance into account, the computations referred to are too grossly and obviously erroneous to deserve the smallest attention.

Vespasian, we believe, would have been very well satisfied with a revenue of 20 millions; and there are good grounds for supposing that the Roman revenue, when at the highest, never amounted to so large a sum. (Gibbon, Vol. I. p. 260.)

Money.

FRENCH MONEY.—From about the year 800, in the reign of Charlemagne, to the year 1103, in the reign of Philip I., the French *livre*, or money unit, contained exactly a pound weight, or 12 ounces (poids de marc) of pure silver. It was divided into twenty sols, each of which, of course, weighed $\frac{1}{20}$ th of a pound. This ancient standard was first violated by Philip I., who made a considerable diminution of the quantity of pure silver contained in the sols. The example having been once set, it was so well followed up, that, in 1180, the livre was reduced to less than *one-fourth* part of its original weight of pure silver. In almost every succeeding reign there was a fresh diminution. “*La monnoye*,” says Le Blanc, “qui est la plus précieuse et la plus importante des mesures, a changé en France presque aussi souvent que nos habits ont changé de mode!” And to such an extent had the process of degradation been carried, that, at the epoch of the Revolution, the livre did not contain a SEVENTY-EIGHTH part of the silver contained in the livre of Charlemagne! It would then have required 7885 livres really to extinguish a debt of 100 livres contracted in the ninth or tenth centuries; and an individual who, in that remote period, had an annual income of 1000 livres, was as rich, in respect to money, as those who, at the Revolution, enjoyed a revenue of 78,850 livres. (Pauquet, *Traité des Mesures, Poids, &c.* p. 693.)

History of the Money of France.

Degradation of the Livre

We subjoin an abridged table, calculated by M. Denis, exhibiting the average value of the French livre in different periods, from the year 800 to the Revolution:

Reigns.	Years.	Value of the Livre in the Current Money of 1789.		
		Livres.	Sols.	Den.
From the 32d year of Charlemagne to the 43d year of Philip I., — or from	800 to 1103,	78	17	0
Part of the reign of Philip I., Louis VI., and VII. —	1103 — 1180,	18	13	8
Philip II. and Louis VIII. —	1180 — 1226,	19	18	4½
Louis IX. and Philip IV. —	1226 — 1314,	18	3	5
Louis X. and Philip V. —	1314 — 1322,	17	3	5
Charles IV. and Philip VI. —	1322 — 1350,	14	11	10
John, —	1350 — 1364,	9	19	2½
Charles V. —	1364 — 1380,	9	9	8
Charles VI. —	1380 — 1422,	7	2	3
Charles VII. —	1422 — 1461,	5	13	9
Louis XI. —	1461 — 1483,	4	19	7
Charles VIII. —	1483 — 1498,	4	10	7
Louis XII. —	1498 — 1515,	3	19	8
Francis I. —	1515 — 1547,	8	11	2
Henry II. and Francis II. —	1547 — 1560,	8	6	4½
Charles IX. —	1560 — 1574,	2	18	7
Henry III. —	1574 — 1589,	2	12	11
Henry IV. —	1589 — 1610,	2	8	0
Louis XIII. —	1610 — 1643,	1	15	3
Louis XIV. —	1643 — 1715,	1	4	11
Louis XV. —	1715 — 1720,	0	8	0
Louis XV. and XVI. —	1720 — 1789,	1	0	0

Money.

Those who wish for a full and detailed account of the various changes in the weight and purity of the French coins, may, besides the excellent work of Le Blanc, consult the elaborate and very complete tables at page 905 of the *Traité des Mesures* of Pauton; and at page 197 of the *Essai sur les Monnoies* of Dupré de St Maur.

It was not to be expected, that degradations originating in the necessities, the ignorance, and the rapacity of a long series of arbitrary princes, should be made according to any fixed principle. They were sometimes the result of an increase in the denomination of the coins; but more frequently of a diminution of the purity of the metal of which they were struck. A degradation of this kind was not so easily detected, and, in order to render its discovery still more difficult, Philip of Valois, John, and some of the other kings, obliged the officers of the mint to swear to conceal the fraud, and to endeavour to make the merchants believe that the coins were of full value! (Le Blanc, p. 212.) Sometimes one species of money was reduced, without any alteration being made in the others. No sooner, however, had the people in their dealings manifested a preference, as they uniformly did, for the money which had not been reduced, than its circulation was forbidden, or its value brought down to the same level with the rest. (*Id.* Introduction, p. 20.) In order to render the subject more obscure, and the better to conceal their incessant frauds, individuals were at one time compelled to reckon exclusively by livres and sols, at other times by crowns or ecus, and not unfrequently they were obliged to refer in computing to coins which were neither livres, sols, nor crowns, but some multiple or fractional part thereof. The injurious effects of these constant fluctuations in the value of money are forcibly depicted by the French historians. And so insupportable did they become, that, in the fourteenth and fifteenth centuries, several cities and provinces were glad to purchase the precarious and little respected privilege of having coins of a fixed standard, by submitting to the imposition of heavy taxes. (Le Blanc, p. 93.)

In the duchy of Normandy, when it was governed by the English monarchs, there was a tax on hearths paid every three years, called *monetagium*, in return for which the sovereign engaged not to debase his coins. This tax was introduced into England by our early kings of the Norman race; but Henry I. in the first year of his reign, was induced to abandon it, and it has not since been revived. (*Liverpool On Coins*, p. 107.)

According to the present regulations of the French Mint, the coins contain $\frac{9}{10}$ ths of pure metal, and $\frac{1}{10}$ th of alloy. The franc, which is equal to 1 livre, 0 sols, 3 deniers, weighs exactly 5 grammes, or 77.2205 English Troy grains. The gold piece of 20 francs weighs 102.96 English grains. (Peuchet, *Statistique Elementaire de la France*, p. 538.)

Of England.

ENGLISH MONEY.—In England, at the epoch of the Norman Conquest, the silver, or money pound, weighed exactly twelve ounces Tower weight. It was divided into twenty shillings, and each shilling into twelve pence, or sterlings. This system of coinage, which is in every respect the same with that

Money.

established in France by Charlemagne, had been introduced into England previously to the invasion of William the Conqueror, and was continued, without any alteration, till the year 1300, in the 28th Edward I., when it was for the first time violated, and the value of the pound Sterling degraded to the extent of $1\frac{1}{2}$ per cent. But, the really pernicious effect of this degradation did not consist so much in the trifling extent to which it was carried by Edward, as in the example which it afforded to his less scrupulous successors, by whom the standard was gradually debased, until, in 1601, in the reign of Queen Elizabeth, 62s. were coined out of a pound weight of silver. This was a reduction of above two-thirds in the standard; so that all the stipulations in contracts, entered into in the reigns immediately subsequent to the Conquest, might, in 1601, and since, be legally discharged by the payment of less than one-third of the sums that had been really bargained for. And yet the standard has been much less degraded in England than in any other country!

Degradation of the Pound Sterling.

The tables annexed to this article give an ample account of these degradations, and also give the weight of the gold coins, and the proportional value of gold to silver, estimated both by the mint regulations, and by the quantity of fine gold and fine silver contained in the different coins.

SCOTTISH MONEY.—In the same manner as the English had derived their system of coinage from the French, the Scots derived theirs from the English. From 1296 to 1355, the coins of both divisions of the island were of the same size and purity. But, at the last mentioned period, it was attempted to fill up the void occasioned by the remittance of the ransom of David II. to England, by a degradation of the coins. Till this time, the money of Scotland had been current in England, upon the same footing with the money of that country; and the preservation of this equality is assigned by Edward III. as a reason for his degrading the English coins. But this equilibrium was soon after deranged. In the first year of Robert III. (1390), the Scottish coin only passed for half its nominal value in England; and, in 1393, Richard II. ordered that its currency, as money, should entirely cease, and that its value should be made to depend exclusively on the weight of the genuine metal contained in it. "To close this point at once," says Mr Pinkerton, "the Scottish money, equal in value to the English till 1355, sunk by degrees, reign after reign, owing to succeeding public calamities, and the consequent impoverishment of the kingdom, till, in 1600, it was only a twelfth part of the value of English money of the same denomination, and remained at that point till the union of the kingdoms cancelled the Scottish coinage."—(*Essay on Medals*, Vol. II. p. 99.)

The tables at the end of this article exhibit the successive degradations both of the Scottish silver and gold coins.

At the Union, in 1707, it was ordered that all the silver coins current in Scotland, foreign as well as domestic, except English coins of full weight, should be brought to the Bank of Scotland, to be carried to the mint to be recoinced. In compliance with this order, there was brought in,

Money.

	L.	s.	d.
Of foreign silver money (Sterling),	132,080	17	9
Milled Scottish coins,	96,856	15	0
Coins struck by hammer,	142,180	0	0
English milled coin,	40,000	0	0
Total,	L.411,117	10	9

Mr Ruddiman conjectures, apparently with considerable probability, that the value of the Scottish gold coins, and of the silver coins not brought in, amounted to about as much more. Much suspicion was entertained of the measure of a recoinage; and that large proportion of the people who were hostile to the Union, and who did not conceive it could be permanent, brought very little of their money to the bank. Only a few of the hoarded coins have been preserved, the far greater part having either been melted by the goldsmiths, or exported to other countries. (Preface to Anderson's *Diplomata*, p. 176.)

Of Ireland.

IRISH MONEY.—The gold and silver coins of Great Britain and Ireland are now the same, and have been so for a considerable period. The rate, however, at which these coins circulate in Ireland, or their nominal value as money of account, is $8\frac{1}{2}$ per cent. higher than in Great Britain. This difference of valuation, which is attended with considerable inconvenience in adjusting the money transactions between the two countries, has subsisted since 1689. For an account of the various species of metallic money which have at different times been current in Ireland, we must refer our readers to Mr Simons' *Essay on Irish Coins*, *—a work pronounced by Mr Ruding to be "the most valuable of all the publications on the coinage of any part of the united empire."—(*Annals of the Coinage*, Preface, Vol. 1. p. 11.)

Of Germany, &c.

MONEY OF GERMANY, SPAIN, &c.—A similar process of degradation had been universally carried on. "In many parts of Germany, the florin, which is still the integer, or money of account of those countries, was originally a gold coin, of the value of about 10s. of our present money (old coinage). It is now become a silver coin, of the value of only 20d.; and its present value, therefore, is only equal to a sixth part of what it was formerly. In Spain, the maravedi, which was in its origin a Moorish coin, and is still the money of account of that kingdom, was in ancient times most frequently made of gold. Le Blanc observes, that, in 1220, the maravedi weighed $8\frac{1}{2}$ grains of gold, equal in value to about 14s. (old coinage) of our present money. But this maravedi, though its value is not quite the same in all the different provinces of Spain, is now become a small copper coin, equal in general to only $\frac{1}{2}$ of an English penny! In Portugal, the re, or reis, is become of

no greater value than $\frac{1}{10}$ of an English penny; it is so small, that, in estimating its value in other coins, it is reckoned by hundreds and thousands. The moeda, or moidore, is equal to 4800 reis; and this little coin has now, in fact, no existence but in name. Such has been the fate of all these coins, and such is their present state of their depreciation."—(*Liverpool on Coins*, p. 111.)

RUSSIAN MONEY.—The following, according to M. Of Russia Storch, are the fluctuations in the weight and value of the rouble, or money unit of Russia, since 1700.

Years.	Weight of the Rouble.	Value in Current Roubles of 1821.
1700	11 40	2 70 $\frac{1}{2}$
From 1700 to 1718,	5 67	1 35
— 1718 — 1731,	4 83	1 15 $\frac{1}{2}$
— 1731 — 1762,	5 16	1 22 $\frac{1}{2}$
— 1762 — 1821,	4 21	1 0

The principle of degradation has not, however, been uniformly acted upon. The quantity of bullion contained in coins of the same denomination has sometimes, though rarely, been increased, and creditors enriched at the expence of their debtors. This method of swindling his subjects is said to have been first practised by Heliogabalus. The Roman citizens being bound to pay into the imperial treasury, not a certain weight of gold, but a certain number of pieces of gold, or aurei, the Emperor, whose vices have become proverbial, in order to increase his means of dissipation, without appearing to add to the weight of the taxes, increased the quantity of metal contained in the aureus; and thus obtained, by a dishonest trick, what it might have been difficult for him to have obtained by a fair and open proceeding. † In France, the value of the coins has been frequently raised. During the early part of the reign of Philippe Bel, who ascended the throne in 1285, the value of the coin had been reduced to such an extent as to occasion the most violent complaints on the part of the clergy and landholders, and generally of all that portion of the subjects who could not raise their incomes proportionably to the reduction in the value of money. To appease this discontent, and in compliance with an injunction of the Popes, the king at last consented to issue new coins, of the same denomination with those previously current, but which contained about three times the quantity of silver. This, however, was merely shifting an oppressive burden from the shoulders of one class to those of another, who were less able to bear it. The degraded money having been in circulation for about sixteen

* Originally printed at Dublin in 1749, in 4to, and reprinted with some additions in 1810.

† Lamp. *Vita Alex. Severi*, Cap. 39.—Perhaps Heliogabalus took the hint from Licinius, a freedman of Cæsar's, who, in his government of the Gauls under Augustus, divided the year into fourteen months instead of twelve, because the Gauls paid a certain monthly tribute!—Dion Cassius, Lib. 72.

Money.

years, by far the largest proportion of the existing contracts must have been adjusted exclusively with reference to its value. No wonder, therefore, that those who were in the situation of debtors should have declared their repugnance to submit to so shameful an act of injustice as was done them by this enhancement of the value of money, and that they should have refused to make good their engagements, otherwise than in money of the value of that which had been current at the time when they were entered into. The labouring class, to whom every sudden rise in the value of money is always injurious, having joined the debtors in their opposition, they broke out into open rebellion. "The people," says Le Blanc, "being reduced to despair, and having no longer any thing to care for, lost the respect due to the edict of his Majesty;—they pillaged the house of the master of the mint, who was believed to have been the chief adviser of the measure, besieged the temple, in which the King lodged, and did all that an infuriated populace is capable of doing." (*Traité Historique des Monnoyes de France*, p. 190.) The sedition was ultimately suppressed; but it is not mentioned whether any abatement was made, by authority, from the claims of the creditors, in the contracts entered into when the light money was in circulation. It seems probable, however, from what is elsewhere mentioned by Le Blanc (*Introduction*, p. 30), that such was really the case.

Increase of
the Value of
the English
Coins in the
Reign of
Edward VI

The history of the French coinage affords several instances similar to the very remarkable one we have now brought under the notice of our readers; but, in England, the new coinage in the last year of the reign of Edward VI. is the only instance in which the value of money has been augmented by the direct interference of government. Previously to the accession of Henry VIII., the pound of standard silver bullion, containing 11 oz. 2 dwts. of pure silver, and 18 dwts. of alloy, was coined into thirty-seven shillings and sixpence. But Henry not only increased the number of shillings coined out of a pound weight of silver, but also debased its purity. The degradation was increased under his son and successor, Edward VI., in the fifth year of whose reign, seventy-two shillings were coined out of a pound weight of bullion; but this bullion only contained three ounces of pure silver to nine ounces of alloy; so that, in fact, twenty of these shillings were only equal to 4s. 7½d. of our present money, including the seignorage. (*Folkes's Table of English Coins*, p. 34.) It appears from the proclamations issued at the time, and from other authentic documents, that this excessive reduction of the value of silver money had been productive of the greatest confusion. A maximum was set on the price of corn and other necessaries; and letters were sent to the gentlemen of the different counties, desiring them to punish those who refused to carry their grain to market. But it was soon found to be quite impossible to remedy these disorders otherwise than by withdrawing the base money from circulation. This was accordingly resolved upon; and, in 1552, new coins were issued, the silver of which was restored to the old standard of purity, and which, though less valuable than those in circulation during the early part of the reign of Henry VIII., were above four

times the value of a large proportion of the same denomination that had been in circulation for some years before.

Money.

It is clear to demonstration, however, that such a rise in the value of money could not have taken place without occasioning the most violent commotions, had all the coins previously in circulation been debased. Equal injustice, it must be remembered, is always done to the poorest, and not least numerous class of society, by increasing the value of money, as is done to the wealthier classes by depressing it. But, although government had been disposed to sanction so enormous an invasion of the right of property, it is altogether impossible that the country could have submitted to have had 400 or 450 per cent. added to its taxes and other public burdens, by a piece of legerdemain of this kind, or that individuals would have consented to pay so much more than they had originally bargained for. Instead of deserving praise for accomplishing such a measure, Edward VI., by whom the reformation of the coins was begun, and Elizabeth, by whom it was completed, would have justly forfeited the esteem of their subjects, and merited the deepest execration. The truth is, however, that almost no change had been made, during all this period, in the value of the gold coins; and there is, besides, abundance of evidence to show, that a large supply of the old silver coins had remained in circulation. Now, as there is no mention made of the issue of the new coins having been attended with any inconvenience, it is nearly certain, as Mr Harris has remarked, that, during the period of the debasement of the standard, individuals had regulated their contracts chiefly with reference to the gold or old silver coins; or, which is the same thing, that "they had endeavoured, as well as they could, to keep by the standard, as it had been fixed in the preceding times." (*Harris On Coins*, Part II. p. 3.)

We have been thus particular in examining this measure, because it has, of late, been much referred to. It is plain, however, that it can give no support to the arguments of those who have appealed to it as affording a striking proof of the benefits which they affirm must always result from restoring a debased or degraded currency to its original purity or weight. Invariability of value is the great desideratum in a currency. To elevate the standard after it has been for a considerable period depressed, is really not a measure of justice, but the giving a new direction to injustice. It vitiates and falsifies the provisions in one set of contracts, in order properly to adjust those in some other set!

This, however, as we have already remarked, is the only instance in which the government of England has ever interfered directly to enhance the value of money. In every other case, where they have tampered with the standard, it has been to lower its value, or, which comes to the same thing, to reduce their own debts and those of their subjects.

It is unnecessary to enumerate in detail the various bad consequences that must have resulted from these successive changes in the standard of value. But, it deserves to be remarked, that an arbitrary reduction of the standard does not afford any real relief to the embarrassments of the governments by whom

Pernicious
Effects of a
Reduction of
the Stand-
ard.

Money.

it is practised. Their *debts* are, it is true, reduced in proportion to the reduction in the value of the currency, but their *revenues* are also reduced in the same proportion. A degraded piece of money will not exchange for the same quantity of commodities. To whatever extent the standard of money may be reduced, prices must, very soon, be raised to the same extent. If the degradation be 10 *per cent.*, the government, as well as every one else, will, henceforth, be compelled to pay L.110 for those commodities which it might previously have obtained for L.100. To bring the same real value into the coffers of the treasury, it is necessary, therefore, that taxation should be increased whenever the standard is diminished—a measure always odious, and in some countries impracticable.

But a diminution of revenue is not the only bad effect which governments experience from reducing the standard of the currency. A state which has degraded its money, and cheated its creditors, is unable to borrow again on the same favourable terms as if it had acted with perfect good faith. We cannot expect to enjoy the reputation of honesty, at the same time that we are openly pocketing the booty earned by duplicity and treachery. Those who lend money to knaves always stipulate for a proportionably high rate of interest. They must not only obtain as much as they could have obtained from the most secure investments, but they must also obtain an *additional* rate or premium, sufficient to cover the risk they run in transacting with those who have given proofs of bad faith, and on whose promises no reliance can be placed. A degradation of the standard of value is, therefore, of all others, the most wretched resource of a bankrupt government. It will never, indeed, be resorted to, except by those who are alike unprincipled and ignorant. "It occasions," says Dr Smith, "a general and most pernicious subversion of the fortunes of private people; enriching, in most cases, the idle and profuse debtor at the expence of the frugal and industrious creditor; and transporting a great part of the national capital from the hands which were likely to increase and improve it, to those which are likely to dissipate and destroy it. When it becomes necessary for a state to declare itself bankrupt, in the same manner as when it becomes necessary for an individual to do so, a fair, open, and avowed bankruptcy, is always the measure which is both least dishonourable to the debtor, and least hurtful to the creditor. The honour of a state is surely very poorly provided for, when, in order to cover the disgrace of a real bankruptcy, it has recourse to a juggling trick of this kind, so easily seen through, and at the same time so utterly pernicious."—(*Wealth of Nations*, Vol. III. p. 435.)

Some of the bad consequences resulting from a change in the value of money might, indeed, be obviated, by enacting, that the stipulations in all pre-

cedent contracts should be made good, not according to the present value of money, but to its value at the time when they were entered into. This principle, which is conformable to the just maxim of the civil law—*Valor monetæ considerandus atque inspicendus est, a tempore contractus, non autem a tempore solutionis*—was acted upon, to a certain extent, at least, by the Kings of France, during the middle ages. Ordonnances of Philip le Bel, Philip of Valois, and Charles VI., issued subsequently to their having increased the value of money, or, as the French historians term it, returned from the *foible* to the *forte* monnaie, are still extant, in which it is ordered, that all previous debts and contracts should be settled by reference to the previous standard. But although the same reason existed, it does not appear that any such ordonnances were ever issued when the value of money was degraded. It is obvious, indeed, that no government could derive any advantage whatever from reducing the value of money, if it were to order, as it is in justice bound to do, that all existing contracts should be adjusted by the old standard. Such a measure would reduce the revenue without reducing the incumbrances of the state; while, by establishing a new standard of value, and unsettling all the notions of the public, it would open a door for the grossest abuses, and be productive of infinite confusion and disorder in the dealings of individuals.

The odium and positive disadvantage attending the degradation of the value of metallic money, appears to have at length induced almost all governments to abstain from it. But they have only renounced one mode of playing at fast and loose with the property of their subjects, to adopt another and a still more pernicious one. The injustice which was formerly done by diminishing the quantity of bullion contained in the coins of different countries, is now perpetrated with greater ease, and to a still more ruinous extent, by the depreciation of their paper currency.*

In the long period from 1601 to 1797, no change was made in the standard of money in this country. A project for enfeebling the standard had indeed been entertained, both in 1626 and 1695; but, in the former instance, it was quashed by the celebrated speech addressed by Sir Robert Cotton to the Lords of the Privy Council, and in the latter by the opposition of Mr Montague, then Chancellor of the Exchequer, in the House of Commons, and by the impression made by the writings of Mr Locke, by whom the injustice of the scheme was admirably exposed, out of doors. It was reserved for Mr Pitt to set aside a standard which had been thus preserved inviolate for nearly two centuries. The Order in Council of the 25th February 1797, and the acts of Parliament by which it was followed up, effected a total change in our ancient monetary system; and, instead of the old standard, gave us the *self-interest*.

Money.

From 1601 to 1797, no change made in the Standard.

* In the sixth volume of the *Cours d'Economie Politique* of M. Storch, there is a very instructive account of the paper money of the different continental states. We can confidently recommend it as containing a great deal of new and important information.

Money. *ed views and opinions of twenty-four irresponsible individuals.* The circulation of Bank of England paper was secured, by its being exclusively issued in payment of the dividends, or of the interest of the public debt, and by its also being received as cash, in all payments into the exchequer; but no attempt was made to sustain the value of this paper on a par with the value of gold or silver. Full power was given to the directors of a private banking company to raise or depress the value of money, as their interest or caprice might suggest. They were enabled to exchange unlimited quantities of bits of engraved paper, of the intrinsic worth, perhaps, of 5s. a quire, for as many, or the value of as many, hundreds of thousands of pounds. And, in such circumstances, our only wonder is, not that paper money became depreciated, but that its value was not more reduced—that a still greater quantity of bank-notes were not thrust into circulation.

Effects of the Restriction in 1797, in degrading the Value of Bank Paper.

For the first three or four years after the restriction, the Directors, ignorant, perhaps, of the nature of the immense power which had been placed in their hands, seem to have regulated their issues nearly on the same principles that they had regulated them by, while they were obliged to pay in coin. It appears, by the *Tables of the Price of Bullion*, published by order of the House of Commons, that, until 1801, bank-notes were on a par with gold. In 1801 and 1802, however, they were at a discount of from 8½ to 7½ per cent.; but they again recovered their value; and, from 1803 to 1809, both inclusive, they were only at a discount of L.2, 13s. 2d. per cent. But, in 1809 and 1810, the Directors appear to have totally lost sight of every principle by which their issues had previously been governed. The average amount of bank-notes in circulation, which had never exceeded 17½ millions, nor fallen short of 16½ millions in any one year from 1802 to 1808, both inclusive, was, in 1809, raised to L.18,927,833; and, in 1810, to L.22,541,523. The issues of country bank paper were increased in a still greater proportion; and, as there was no corresponding increase in the business of the country, the discount on bank-notes rose from L.2, 13s. 2d. in 1809, to L.13, 9s. 6d. per cent. in 1810! The recommendation to return to cash payments, contained in the *Report of the Bullion Committee*, presented to the House of Commons in 1810, appears to have given a slight check to the issues of the Bank. All apprehensions from this quarter were, however, speedily dissipated; for, in May 1811, when guineas were notoriously bought at a premium, and bank-notes were at an open discount, as compared with gold bullion, of upwards of 10 per cent., the House of Commons not only refused to fix any certain period for reverting to cash payments, but actually voted a resolution, declaring that the promissory notes of the Bank of England had hitherto been, and were AT THAT TIME, held to be, in public estimation, equivalent to the legal coin of the realm!

Extraordinary Resolution of the House of Commons.

This ever memorable resolution—a resolution which took for granted, that a part was equal to a whole—that L.90 and L.100 were the same thing—relieved the Bank from all uneasiness respecting the interference of Parliament, and stimulated the Di-

rectors to increase the number of their notes in circulation. The consequence was, that, in 1812, they were at an average discount of 20½; in 1813, of 23; and, in 1814, of 25 per cent. This was the maximum of depreciation. The importation of foreign corn, subsequent to the opening of the Dutch ports in 1814, by occasioning a great decline of the price of the principal article of agricultural produce, produced an unprecedented degree of distress, first among the farmers, and latterly among the country bankers. It is estimated that, in 1814, 1815, and 1816, no fewer than 240 private banking companies either became bankrupt, or, at least, stopped payment; and the reduction that was thus occasioned in the quantity of bank-notes in circulation, raised their value so rapidly, that, in October 1816, the discount was reduced to L.1, 8s. 7d. per cent. In 1817 and 1818, the average discount on bank paper, as compared with gold, did not exceed L.2, 13s. 2d. per cent. In the early part of 1819, it rose to about 6 per cent.; but it very soon declined; and, for the last two years, paper has been nearly on a level with gold. (See Table No. V. annexed to this article.)

Money.

Nothing that has ever happened in the history of the country has proved more injurious to its best interests than these fluctuations. From 1809 to 1815, the creditors of every antecedent contract, landholders whose estates had been let on lease, stockholders and annuitants of every description—all, in short, who could not raise the nominal amount of their claims or of their incomes proportionably to the fall in the real value of money, were robbed of a corresponding portion of them. The injustice that would have been done to the creditors of the state and of individuals, who had made their loans in gold or paper equivalent to gold, by raising the denomination of the coin 25 per cent., however gross and palpable, would not have been greater than was actually done them in 1814, by compelling them to receive payment of their just debts in paper depreciated to that extent. Circumstances which could neither be controlled by the Bank of England nor the Government, put an end, as we have just seen, to this monstrous system. But we are still suffering, and will long continue to suffer severely, for the folly and injustice of which we have been guilty. The mischief occasioned by the sudden reduction of the paper currency, and the consequent rapid augmentation of its value, has been still greater than what had previously been caused by its depreciation. The hardship occasioned by the subversion of private fortunes, and by the change in the debts and credits of individuals, might be, in both cases, nearly equal. A vast amount of public debt was, however, contracted during those years in which the depreciation was greatest; and the state is now paying this debt, borrowed when the bank-note was not worth more than 14s. or 15s., with bank-notes whose value is increased to 20s. The salaries, too, of all our public officers, and the expences of the army and navy, and of all our other public establishments, had been generally augmented proportionably to the reduced value of money. And as no corresponding reduction has been made from the sums voted on their account since the currency recovered its value,

Money.

it is easy to perceive, that a very great addition has thus been made to the public expenditure. All those taxes, too, which were imposed when the currency was depreciated, must now, though not nominally, be really increased in the same proportion; so that, when sufficient allowance has been made for the difference in the value of money, it is doubtful whether the country be not more heavily burdoned at this moment than it was in 1813 and 1814, though we have since got rid of the income-tax—a tax which produced about 14 millions a year!

Such is but a brief and imperfect outline of the very great and almost irreparable injury which the late fluctuations in the value of the currency have entailed on the country. And yet, strange to tell, there is a considerable party amongst us who, not satisfied with this pernicious transference of property from the pockets of those who ought to possess it, to the pockets of those who have no right to it whatever—are clamouring for a fresh reduction of the standard! And it is, indeed, unquestionably true, as we have already had occasion to show, that after a currency has been for a considerable period depreciated, equal injustice is done by again raising its value, as was done by first depressing it. There is good reason, however, to doubt, whether the depreciation from 1809 to 1815 (for the depreciation of $2\frac{1}{2}$ per cent. during the seven preceding years is too inconsiderable to be taken into account) extended over a sufficiently lengthened period to have warranted the Legislature in departing from the old standard. But, without giving any opinion on this point, which is confessedly one of considerable difficulty, it is sufficient to remark, that the value of the currency was raised, *independently altogether of the interference of Government*. The destruction of country bank paper, occasioned by the renewed intercourse with the continent, and the consequent introduction of cheap foreign corn, had raised the value of paper currency, in October 1816, to within $1\frac{1}{2}$ per cent. of par. Now, as the act 59th Geo. III. was not passed until 1819, and as the currency had not been depreciated in the interim, we frankly confess our inability to discover the grounds on which it is affirmed to have been the cause of that rise in the value of money which took place *three years before it was in existence!* The proceedings in 1819 did not really add 3 per cent. to the value of bank paper, nor were they intended to raise it. Their great object was to shut the door against a new depreciation, and to prevent the value of paper, which had, for three years, been nearly on a level with gold, from being again degraded. By maintaining the old standard, or, which is the same thing, by maintaining the currency at a value nearly corresponding to that to which it had attained in 1816, 1817, and 1818, Parliament certainly gave permanence to the serious injury which the rise in the value of money had occasioned to the debtors in all the contracts entered into between 1810 and 1815; but if, instead of maintaining this old standard, they had raised the mint price of bullion to its market

price in 1814, they would have done an equal injury to the far more numerous body of creditors, in all the contracts entered into previously to 1810, and in the three years subsequent to autumn 1816.

Money.

In these circumstances, it was impossible to adopt any measure capable of giving general satisfaction to those whose interests were so widely different; and against which many plausible, and even forcible objections, might not have been stated. We are firmly persuaded, however, that the Legislature followed that course which was, on the whole, the wisest and most advantageous. It must be remembered, that much of that inconvenience and distress, which must always result from every sudden rise in the value of money, had been got over in 1817 and 1818. The rents of such farms as had been let during the depreciation had been very generally reduced; a vast number of annuity bonds had been cancelled, and prices and wages had begun to accommodate themselves to the new scale of value. The adoption of Mr Peel's bill only gave stability to arrangements which had been brought about by the natural course of events; and, by fixing the standard at its former limit, secured us, as long at least as we have good sense and honesty to maintain it inviolate, against the risk of future derangement and fluctuation.

Standard as now fixed ought to be maintained inviolate.

But, even if it could be shown that the act 59th Geo. III. was inexpedient at the time when it was passed, that would add but little real strength to the plea of those who are now contending for its repeal. Every objection which it was possible to make to the degradation of the standard in 1819, must apply with tenfold force to the scheme for degrading it in 1821: while, on the other hand, all the arguments that could have been urged in favour of the measure at the former period must now be proportionably weakened. Two years more have been afforded for the completion of those arrangements which had been begun in 1817 and 1818; and an immense variety of new contracts and engagements have been entered into, exclusively with reference to the present value of money. A fresh reduction of the standard would vitiate all these engagements, and plunge us of new into that confusion and embarrassment from which we have now nearly escaped. We should again witness the most pernicious subversion of private fortunes. Debtors would be again enriched at the expence of their creditors; the ignorant and unwary would again become the prey of the cunning and the crafty; and capitalists would be eager to transfer their stock from a country where it would be impossible to lend it, except at the risk of getting it repaid in a depreciated currency. "Whatever, therefore," to avail ourselves of the just and forcible expressions of Mr Harris, "may be the fate of future times, and whatever the exigency of affairs may require, it is to be hoped that that most awkward, clandestine, and most direful method, of cancelling debts by debasing the standard of money, will be the last that shall be thought of."—(*On Money and Coins*, Part II. p. 108.)

Act 59th Geo. III. did not raise the Value of the Currency.

* At the period when Mr Peel's bill was passed, bullion was at L. 4 an ounce; consequently, the depreciation was only L. 2, 13s. 2d. per cent.

TABLES RELATIVE TO THE MONEY OF GREAT BRITAIN AND OTHER COUNTRIES.

No. I. ENGLISH MONEY.—*Account of the English Silver and Gold Coins; showing their Value; the Seignorage or Profit upon the Coinage, and the Price paid to the Public by the Mint, for the Pound Troy of Standard Gold and Silver, from the Conquest to the year 1816. (This and the next Table, No. II., are taken from Part II. of Essays on Money, Exchanges, and Political Economy, by Henry James.)*

* 1527—Henry VIII.] The Saxon or Tower-pound was used at the mint up to this time, when the pound Troy was substituted in its stead. The Tower-pound was but 11 oz. 5 dwts. Troy; so that, from the Conquest to the 28th of Edward I., twenty shillings in tale were exactly a pound in weight.

† 1666—18 Charles II.] The seignorage on the coinage was at this time given up, and the gold bullion brought to the mint has ever since been coined free of expence. A seignorage of $6\frac{1}{2}\%$ per cent was imposed on the coinage of silver by 56th Geo. III.

No. II. ENGLISH MONEY.—ACCOUNT of the Quantity of Fine Silver coined into σ for the Pound Sterling; the Quantity of Standard Silver, of 11 oz. 2 dwts. fine, and 18 dwts. alloy, contained in 20s. or the Pound Sterling, and the Quantity of Standard Silver which was delivered to the Mint, by the Public, for 20s. of Silver Money, in the different Reigns; from the time of Edward I. to the Reign of George III.—A similar Account with respect to Gold.—And an Account of the proportionate Value of Fine Gold to Fine Silver, according to the number of Grains contained in the Coins; and the proportionate Value of Fine Gold to Fine Silver, according to the Price paid by the Mint to the Public.—Calculated in Grains, and 1000 Parts, Troy-weight.

A. D.	Anno Regni.	SILVER.			GOLD.			7.	8.
		1. Number of Grains of Fine Silver in 20 Shil- lings, or the £ Sterling, as coined by the Mint Indentures.	2. Number of Grains of Standard Silver, 11 oz. 2 dwts. fine in 20 Shil- lings, or the £ Sterling, as coined by the Mint Indentures.	3. Number of Grains of Standard Silver which 20s. were worth, according to the Price paid by the Mint to the Public.	4. Number of Grains of Fine Gold in 20 Shil- lings, or the £ Sterling, as coined by the Mint Indentures.	5. Number of Grains of Standard Gold, 22 ca- rats fine in 20s. or the £ Sterling, as coined by the Mint Indentures.	6. Number of Grains of Standard Gold which 20 Shillings were worth according to the Price paid by the Mint to the Public.	7. Proportionate Value of Fine Gold to Fine Silver, accord- ing to the quan- tity of each Metal contained in the Coins.*	8. * 1551—5 Edward VI.] The coinage of debased silver money in the 5th year of Edward VI. of 3 oz. fine, ought more properly to be considered as Tokens. The sum of £120,000 only was so coined. (See James's *Essays*, Chap. IV.)

† 1816—56 George III.] The Government having taken the coinage of silver into its own hands, there is at present no fixed price paid to the public, by the mint, for standard silver. And supposing the Government to continue the present mint regulations, and to keep gold at 77s. 10½d. an ounce, as the price of silver varies, the relative value of gold to silver will vary in like proportion.

No. III. SCOTS MONEY.—Account of the Number of Pounds, Shillings, and Pennies Scots, which have been coined out of One Pound Weight of Silver, at different times; with the degree of Purity of such Silver, or its Fineness, from the year 1107 to the year 1601. (From Cardonnel's Numismata Scotica, p. 24.)

* The London Assays in this Table have been made by Robert Bingley, Esq. F. R. S. the King's Assay Master of the Mint, and those at Paris by Pierre Frederic Bonneville, Essayeur du Commerce, as published in his elaborate work on the coins of all nations.

Specimens of all the foreign coins brought to London for commercial purposes have been supplied for this Table from the Bullion Office, Bank of England; by order of the Bank Directors, and have been selected by John Humble, Esq., the chief of that office, who also examined the tables in their progress. It may likewise be added, that the Mint Reports of these commercial coins are chiefly from average assays; and that all the computations have been carefully verified by different calculators. (Note by Dr Kelly, to second edition of the *Cambist*, published in 1821.)

S. S.

MONMOUTHSHIRE, a county of England, which, before the year 1535, was a portion of the principality of Wales. It is now no longer under the jurisdiction of the Welsh Judges, but it still is so far considered as not an English county, that the causes which are removed for trial from the principality to England are tried within it. The greater part of the inhabitants still speak one of the three dialects of the Welsh language; in some of the churches the worship is exclusively conducted in that tongue, in many it is celebrated in Welsh and English alternately, and only in the towns in English alone.

Boundaries and Extent. Monmouthshire is bounded on the north by Herefordshire, on the east by Gloucestershire, on the south by the river Severn, and on the west by the Welsh counties of Brecon and Glamorgan. Its greatest length is 33 miles, its greatest breadth 26, and its circumference 110 miles. The square extent is 516 miles, or 330,240 acres.

Soil and Face of the Country. The face of the country is highly diversified, exhibiting every gradation from lofty and bleak mountains, to highly verdant and beautiful sequestered vallies. Some of the mountains, as the Sugar-loaf, of 1850 feet, the Blorenge of 1720, and the Skyrid-vawr of 1498 feet, with some others, display their summits for many months covered with snow, whilst their sides, near the bottom, are cultivated with the different species of grain, and terminate in meadows of the most luxuriant fertility. Mr Fox, in his Agricultural Survey of this county, divides it into three

districts. The first, comprising the southern division, consists in part of large tracts of moor or marsh land, exhibiting in some parts of it a great depth of unctuous loamy soil, and in others a vast body of black peaty earth. In other parts of this district the soil is of a light loamy consistence, highly favourable to the growth of various trees. Another portion is a mixture of clay and loam, forming fertile meadows, and above them an excellent red soil, in which turnips, potatoes, and grain, liberally repay the cultivator. The second division comprehends the eastern part of the county, extending to a considerable, but varying distance on both sides the river Usk. The soil is of a faint red colour, highly grateful, and being carefully cultivated, the whole displays the appearance of great fertility. The third division comprises the western and most mountainous parts of the county. The soil on the hills is generally of a thin peaty nature, covering strata of stone, underneath which are mines of coal and iron ore, of most unbounded productiveness. The low lands in this division are chiefly in the state of meadow and pasture, whilst the middle lands are occupied partly by pasture and partly by arable husbandry.

The rivers of this county have been generally celebrated for the picturesque scenery which their banks display, and which, added to the many remains of antiquity that are to be seen near them, invite the visits of numerous parties in the summer months, and afford the highest gratification to travellers of taste. The most eminent of these rivers, in beauty as well as

Monmouth-
shire.

utility, is the Wye. It rises on the southern side of Plinlimmon, in Montgomeryshire, and forming the division line between the counties of Brecon and Radnor, passes through a part of Herefordshire, and enters this county at Dizon, becomes navigable for boats at Monmouth, and empties itself into the Severn at Chepstow. The beauties of this stream are derived from the sinuosities of its course, the uniformity of its breadth, the picturesque country through which it flows, and, among many other striking objects on its banks, from the Abbey of Tintern, and the mansion and grounds of Piercefield. The tide in this river rises at Chepstow to a greater height than in any other English river; at the bridge of that town the elevation has been between 50 and 60 feet, and it takes place with most unusual celerity. The Usk rises in the black mountains of Brecknockshire, and when it enters this county, passes between lofty hills, which gives its borders every variety of beauty that landscape can display. It is navigable for a short distance, and only for barges. It abounds with salmon, some of which are frequently caught in it of a most unusual size. The other rivers are the Rumney, the Monnow, and the Ebwy, each of which has peculiar and characteristic beauties.

Canals and
Rail-roads.

The heavy productions of this county, iron, coal, and limestone, have given rise to the establishment of various canals for their conveyance. The Monmouthshire canal begins at Newport, and dividing into two branches, connects that town, by one, with Pontypool and Pontnewyd, and by the other with Crumlin Bridge. The Brecknockshire canal unites with this, and passes, in its course, under a hill by means of a tunnel 360 feet. The county is most abundantly supplied with rail-roads, leading from the principal mining districts to the canals; and many private mines have small rail-ways, provincially called tram-roads, leading to the principal iron rail-roads, by which a facility is afforded to the conveyance of productions through a country whose roads are eminently bad.

Agriculture.

The agricultural productions are wheat, barley, and oats, with a few pease and beans. They are sufficient for the supply of the inhabitants, and the small surplus, as well as much fruit, is sent to the markets of Bristol. On the arable lands the system of summer fallowing is pretty generally pursued. The principal manure is lime, the stone from which it is burnt being most abundant. The oxen of this county are highly esteemed both for draught and for fattening. They are usually a deep red colour, short in the legs, and compact in the carcase, being a cross between the breeds of Hereford and Glamorgan. They are very docile in harness, and will fatten so as to weigh from seven to nine hundred weight. They are much sought after by the English graziers, who purchase them when young, and after employing them in labour, fatten them for the butcher. The sheep are remarkably small, the wool is short and coarse, but the flesh is fine in the grain, and of a most delicate flavour. Of late years much improvement has been made in the flocks by judicious crosses with the Cotswold, Southdown, and Dorset sheep. The horses of the county are generally a very man-

Live Stock.

gre, light, and uncompact breed. In this county and Brecknockshire the breeding and rearing of mules is carried to a greater extent than in any other part of the island. They are found very beneficial in the hilly districts, where the mines are worked. Male asses are imported from Spain and the south of France, to propagate, and the mules are frequently of a size and strength equal to the natives of those countries.

Monmouth-
shire.

The landed property of this county is in few hands, but divided generally into small farms, varying in rent from L.70 to L.200. The leases are generally for 21 years, and the conduct of the landlords to their tenants is liberal, and somewhat parental. Many farms are held by copy of the court roll.

Division of
Property.

The greatest riches of Monmouthshire are derived from its mines. Coal and iron ore abound in all the hills. The facilities for interior conveyance have been before noticed. The coals of this county have, under the act of Parliament for constructing the canal, the peculiar privilege of being carried to the opposite shore, including the city of Bristol and the towns on that coast, as far as Bridgewater, without paying the water-borne duty. This gives to them a monopoly of those large markets, to the exclusion of the collieries in the forest of Dean, and of Glamorgan and Carmarthenshire. The proprietors of these last mentioned mines have petitioned Parliament to be placed on a similar footing, but, after a most patient investigation of all the circumstances in a committee, the peculiar rights of the coals brought by the Monmouthshire canal were confirmed. The iron mines were worked as early as the reign of Queen Elizabeth, and made a rapid progress; but owing to the great consumption of wood, which soon caused a scarcity of fuel, they had sunk very low till about fifty years ago, when the mode of making iron from coke was introduced. This discovery, with the improvements in machinery, has given a vast impulse to the working the iron mines. Fifteen or sixteen works, on the largest scale, and many smaller ones, have been established. At one period, the weekly delivery of pig-iron and bar-iron from these different works is stated to have amounted to a thousand tons.

The abundance of iron, and the facility of intercourse with Cornwall, have led to the establishment of some very extensive manufactories of tin plates. The manufactory of a kind of Japan ware was first practised in England by Thomas Allgood of Pontypool, in the reign of Charles the Second; and though the skill of Birmingham has been successfully exerted to rival the town from whence that ware derived its name, the business is still continued there, but upon a small scale. The manufactory of caps, for which Monmouth was celebrated at the period when Shakespeare wrote, has been long abandoned. At Newport and Chepstow there are some considerable establishments for building ships.

Manufac-
tures.

Few parts of the island contain more numerous or better preserved remains of Roman and Saxon antiquity than this county. Caerleon was long the metropolis of the British dominions, and the residence of King Arthur. The ruins of the wall, 530 yards by 480, are still to be traced; and the vast

Antiquities.

Monmouth-
shire.

masses of stones, which are now in a confused state, show that it was formerly a place of great importance. There are many Roman encampments still visible. The remains of the abbeys of Gracedieu, Llantarnam, Llanthony, and Tintern, and of the priories of Goldcliff, Thynemark, Monmouth, and Usk, invite the close examination of antiquarians. The castles of Abergavenny, Carleon, Caldecot, Castell-Glas, Chepstow, Dinham, Grosmont, Llanfair, Scenfrith, Striguil, Usk, and Llandeilo, are the most remarkable among numerous other similar buildings. The character of the architecture of the churches of Abergavenny, Carleon, Caldecot, Chepstow, Newport, and others, discovers a very ancient origin. The antiquities of Monmouthshire would, indeed, require a volume for their delineation.

Civil and
Ecclesiasti-
cal Affairs.

The county gives the title of Earl of Abergavenny to the family of Neville, not by creation or writ, but as possessors of the castle of that town. The Irish Marquis of Ormond derives from it the title of Baron Butler, and the Duke of Beaufort is Baron Herbert of Chepstow and Rogland, and Baron Beaufort of Caldecot Castle. The members to the House of Commons are two for the county and one for the united boroughs of Monmouth, Newport, and Usk. The whole county is within the diocese of Llandaff, except three parishes, which are in St David's, and three others in that of Hereford. The English Judges, on the Oxford circuit, hold the assizes twice a year at Monmouth.

Divisions
and Popu-
lation.

The county is divided into six hundreds, and contains one hundred and twenty parishes and seven market towns. At the census of 1811, there were returned 12,127 houses, inhabited by 12,548 families. Of these families 5815 were employed in agriculture, 4812 in trade and manufactures, and 1916 in other occupations. The number of inhabitants was 62,127, viz. 30,987 males and 31,140 females. The baptisms of males, the preceding years, were 642, and of females 632. The burials of males were 514, of females 444. The marriages were 416. The towns which contain more than 1000 souls are as follows:

	Houses.	Inhabitants.
Monmouth,	675	3503
Abergavenny,	575	2815
Ushkawood,	416	2728
Chepstow,	429	2581

Montgo-
meryshire.

See Coxe's *Historical Tour in Monmouthshire*; *History of Monmouthshire*, by David Williams; *Do-novan's Descriptive Excursions through South Wales and Monmouthshire*; *Strange's Roman Antiquities at Caerleon and Caerwent*; *Fox's General View of the Agriculture of Monmouthshire*. (w. w.)

MONTGOMERYSHIRE, an inland county of North Wales. It is bounded on the east by Shropshire, on the north by Denbighshire and Merionethshire, on the west by Cardiganshire and Merionethshire, and on the south by Radnorshire. It is of an irregular form; its greatest length, from north to south, is thirty-six miles, and its mean breadth, from east to west, is about thirty-two miles. Its area, in square miles, is estimated to be 982, or 620,720 statute acres; but is probably overrated.

It is a county of very irregular surface, composed, in the centre, of a ridge of lofty mountains, which nearly divide it, and from which various branches project, which, though not equal in height to the mean ridge, attain a great elevation. The loftiest of the mountains, Plinlimmon, or Pumlumon, is continued through Montgomeryshire and enters Merionethshire; from its centre various streams run, some to the east and some to the west, the former into the Severn, and the latter to the sea at Cardigan Bay. Plinlimmon is, at the highest point, 2463 feet above the level of the sea; the other mountains that branch from it are Llandinam, 1898 feet, the Long Mountain 1930, and that on which a pillar, to the memory of Lord Rodney, is erected, 1204. From the irregularity of the surface, and the great elevations, the chief part of the county is bare, raw, and barren; but in the valleys between the mountains, there are some most delightful and fertile spots, watered by translucent rivulets, and bordered with the richest forest scenery.

The rivers that run westerly from the mountain ridges are the Traeth-bach, the Maw, and the Dovey. The Wye, the Severn, the Vyrnwy, and the Tanat, which receive several smaller mountain torrents, run to the eastward: the two first, which receive the others, keep nearly a parallel course to the plains of Salop. The Severn, though at first a mere mountain rill, and soon a rapid torrent, speedily assumes a tranquil character, and glides through deep vales till it enters Shropshire, and becomes the second of our English rivers. It is the only stream navigable in this county, but it is passable only at periods of rain by boats, and frequently ship timber lies on its banks a long time, waiting for sufficient water to float it down the stream. A canal has been constructed, connected with the Ellesmere canal in Shropshire; but though completed, it is found to be a very unproductive undertaking. There are some picturesque waterfalls, which invite the inspection of travellers in this romantic county. The

Cascades.

Montgomeryshire.

most remarkable of these is Pystyll-Rhaiadr. The brook, or rather river Rhaiadr, (for, after rains, it deserves the latter name), runs over a gentle declivity for a short distance, and then suddenly precipitates itself over a perpendicular ledge, from whence it falls, rather in the form of spray than in that of a torrent, to the depth of two hundred feet, while the projecting rocks that intercept its fall cause a spectacle and sounds that are highly terrific. This cataract appears in its grandeur only after a wet season, for in very dry weather it is an insignificant rill.

Agriculture.

The agriculture of Montgomeryshire is in a very backward state; not one-eighth of the land is under the plough; about three-eighths of it is devoted to pasture, but the food it produces is small for the extent on which it grows. Nearly half the county is in an uncultivated state, or covered with wood. Some few good cultivators have of late, in some spots, introduced the Norfolk four course system of turnips, barley, clover, and wheat, but it prevails to a very limited extent, owing to the deficiency of capital among the occupiers. The greater part of the arable land is destined to produce corn, without intermission, till it becomes exhausted, when it returns of itself to a very imperfect and unproductive kind of pasture. Though these remarks refer to the greatest part of the county, yet a part of it adjoining to Shropshire forms a very laudable exception, as it is well cultivated, and very prolific, especially on the banks of the Severn. In almost every part of the county hemp is cultivated for domestic use, in small patches, and the making it into cloth forms the employment of itinerant weavers.

Article.

The cows of this county somewhat resemble the Devonshire breed, and are said to have been originally brought from that county. When removed to better pasture, and fattened, they are highly valued by the butchers, because they yield less offal, and collect a greater mass of flesh on the more valuable parts of the body. The sheep are of small size, but their mutton is exquisite. The wool is of very fine quality, and the best Welsh flannels are made from it. There is a very numerous breed of small horses on the mountainous parts of Montgomeryshire, which are nearly in a state of nature. They are known by the name of Merlyns, and range through the whole year over the most elevated parts of the country. By their exposure, and the ease with which they are subsisted, they acquire a very hardy frame, and are capable of performing labour far beyond what their size and apparent strength indicate. They are driven, when needed, into an inclosure, where the best are selected from those that have attained their third year, and the remainder are turned out to range at large as before. Notwithstanding their diminutive size, the greater part of the commodities furnished by the county are conveyed on their backs from one place to another. The vallies in this county have been long celebrated for a breed of excellent horses, introduced originally from the south of Spain, by the Earl of Shrewsbury in the reign of Queen Elizabeth; these, by various crosses, have been much improved, and they now furnish some of the best hunters in the kingdom, from uniting strength with speed.

Name and use.

Limestone is not generally found in this county.

VOL. V. PART II.

and rarely unmixed with argillaceous earth; so that the lime required for building is brought from one extremity to the other by the canal. Coal is only found in an angle of the county, on the borders of Salop; the quantity is small, and its combustive quality causes it to burn so rapidly, as to make it a much more expensive fuel, except in the vicinity of the pits, than either wood or turf.

Minerals.

The mineral which abounds most in the mountains of Montgomery is lead, which is raised in many parts of them. The ore known by the name of *galena*, provincially called potters ore, was formerly discovered in a prodigious vein at Llangynnog, but, after much profitable excavation, the miners reached a fault in the vein, and its continuance has not been yet ascertained. At Llanymynach are the vestiges of mines worked in very remote periods, which exhibit intricate recesses, and form a kind of subterraneous labyrinth. Both copper and lead ore are still found in these ancient mines, and zinc, in unison with sulphuric and carbonic acids, known by the common appellations of calamine, and black-jack. A very rich lead mine at Tallessi was formerly worked, and yielded large profits to its owner, Sir Watkins Williams Wynne; but, owing to a great increase of water, the working has been discontinued. The ranges of mountains are partly composed of schist, from which are drawn large quantities of slates, applied to the covering of houses, or sent to London and Bristol, to be fitted for writing.

Timber.

This was formerly one of the best wooded counties of North Wales, and it has, for the last seventy years, contributed to supply a great part of the best oak timber to the Royal Dock-yards. The size of the Montgomeryshire oaks has made them much prized for naval purposes; some have been felled which have contained more than 600 cubic feet. This oak is of a remarkably good quality, but the difficulty of conveyance has rendered the price very low on the spots where it is grown, and formerly much of even the most valuable quality was used for fuel.

The only manufactures are of woollens, made from the fleeces of their native sheep, and mostly confined to flannels known through England, and highly prized, under the denomination of *Welsh flannels*. They have been imitated both in Lancashire and Yorkshire, but have not been equalled in fineness of texture, combined with softness. The farmers, and even the cottagers, make these flannels; and they are collected by a kind of middle-men, who bring them to the market of Welshpool, whence they are sold to the merchants of Shrewsbury, who distribute them over the kingdom. The annual value sold at the market is about £. 50,000, and the cost of the wool is estimated at about half that amount.

Two members are returned to Parliament, one for the county, and one for the borough of Montgomery, the county town.

In 1811, the population amounted to 53,700 persons; Welshpool then contained 3140, and Montgomery 932.

The most remarkable seats of noblemen and gentlemen are, Powis Castle, Lord Powis; Lydiarth Hall, Sir W. W. Wynne, Bart.; Llangedwen, Mr Wynne; Towyn, E. Corbet, Esq.; Llandinam, M.

MOORE (JOHN, M. D.) was the son of one of the clergymen of Stirling, where he was born in the year 1730. He received his medical education at the University of Glasgow, and at the early age of seventeen, he served as surgeon's mate with the army in Flanders. After the conclusion of peace, he prosecuted his medical studies at Paris, where he was appointed surgeon to the household of the English Ambassador, Lord Albemarle. On his return to Scotland, he settled as a surgeon at Glasgow; and there he quickly rose to extensive and successful practice. In every period of his life he delighted in social intercourse; and during his residence in Glasgow, his leisure hours were, in a great measure, devoted to the enjoyment of society. His vivacity in conversation, and agreeable turn of wit and humour, attracted around him a numerous and respectable circle of acquaintances. Though he did not at this period come before the public as an author, he often wrote occasional poems on the occurrences of the day, for the amusement of the society which he frequented, and of which he formed the principal charm. His acute and just discrimination of the various shades in the manners and dispositions of mankind was even at this time displayed in a series of verses, characteristic of the members of a convivial club to which he belonged.

In the year 1769 he was called, in his medical capacity, to attend the young Duke of Hamilton, who was labouring under a pulmonary complaint, to which he ultimately fell a victim. His attendance at Hamilton subsequently led to his accompanying the brother of his patient to the continent. An extensive and long continued tour through Italy, France, and Germany, opened a wider range to his faculty of investigating the characters of mankind than he had hitherto enjoyed. After spending five years abroad, he settled as a physician in London; and about the same time commenced his literary career, by publishing the fruits of his travels in his *View of Society and Manners in France, Switzerland, and Germany*. This work was so well received that, in 1781, he added to it two volumes, entitled, *A View of Society and Manners in Italy*. A discriminating observer of the customs, passions, and prejudices of mankind, he was admirably qualified to give a correct and interesting view of society and manners in the countries through which he had travelled; and, by means of the epistolary form which he adopted, he has completely succeeded in giving sufficient connection and animation to his Miscellaneous Anecdotes, his Sketches of Distinguished Men, and his Remarks on National Character. In 1785 he published his *Medical Sketches*, consisting chiefly of observations on the Animal Economy and the treatment of Fevers. His next performance, which appeared in the year following, was the celebrated novel of *Zeluco*, in which he has exhibited a character so atrocious, as rather to excite horror, than to afford amusement or instruction. The only prototype of such a personage in fictitious narrative (for surely none ever existed in real life) is

the *Ferdinand Count Fathom* of Smollet, which Dr Moore, doubtless, had in his eye when he undertook this singular delineation. Both characters are utterly devoid of principle, and are equally profligate, perfidious, and selfish. Yet there are different shades in the characters of these fictitious wretches; *Zeluco* is a more daring and hardy, *Fathom* a more pliant and crafty villain. *Fathom*, too, in the commission of all his atrocities, is solely actuated by self interest, or the indulgence of the lowest sensual gratifications; whereas, *Zeluco* is excited to many of his blackest crimes by the strongest evil passions of our nature,—by hatred, envy, and revenge. *Fathom* has perfect command of temper, and never sacrifices his interest to caprice. *Zeluco's* temper, on the other hand, is ungovernable, and he disregards all consequences in the gratification of his rage and malice. The moral effect of all such pictures of depravity may well be doubted. *Fathom*, indeed, who is pointed out as a coward, a thief, and a sharper, is so utterly degraded, loathsome, and disgusting, that the contemplation of his character is only for the time a pollution of the imagination. But the high birth, personal attractions, gentlemanlike accomplishments, and courage of *Zeluco*, may, to an ill regulated mind, extenuate his enormities, and even spread the infection of his wickedness. It is true, that the history of *Zeluco*, who is the only son of a noble and wealthy family in Sicily, is intended to show the fatal consequences of uncontrolled passions, and excessive maternal indulgence: It is true, that, with every advantage of person, birth, and fortune, he is represented as utterly wretched from the depravity of his nature;—it is true, that an awful punishment is awarded to him in the catastrophe, and that he closes his life in paroxysms of penitence. But though the author's design may have been laudable, in the perusal, the moral scope is often as much lost sight of, as the recondite allegories of the *Orlando*, or *Jerusalem Delivered*. Such a picture, too, of the darkest tinges of villany, unmitigated by the intermixture of one good quality, harmonizes so little with the ideas or feelings of this country, that we revolt at its improbability; or, at least, the credence of reality, so essential to the success of every fictitious narrative, is hardly ever excited. Besides, the principal parts of the work are not such as afford scope for the display of the author's peculiar excellencies. The mind, however, is occasionally relieved by scenes of humour and pleasantry, by picturesque sketches, and interesting traits of character. The comic part, indeed, is infinitely superior to the tragic, and in it the author seldom fails. Of *Transfer* we have, perhaps, too much, but Buchanan is an admirable sketch. There is much light humour in the relation of the story of Rosolia, and the comic dialogue is invariably spirited and lively. Though now somewhat sunk in reputation, *Zeluco* was much admired on its first appearance, and was hailed as one of those productions which, by its knowledge of human nature, and reach of mind, redeemed the species of composition to which it belonged from the imputation of frivolity, and elevated fictitious narratives to a higher walk in the paths of literature. In 1792 Dr Moore accompanied Lord Lauderdale to Paris, where he witnessed some of the prin-

Moore
Morayshire.

principal scenes of the Revolution, of which he published an interesting account on his return to England. The same journey supplied him with materials for his *View of the Causes and Progress of the French Revolution*, published in 1795.

The scenes which Dr Moore had hitherto exhibited, both in his travels and fictitious compositions, were copied from the manners of other countries. The novel of *Edward*, which he published in 1796, is entirely confined to the illustration of our domestic usages and national customs. Edward is a foundling, whom chance places under the protection of Mrs Barnet. Under her guidance his mind, which is intended as a contrast to that of Zeluco, gradually unfolds to every amiable and manly virtue. His character is exhibited in many trying situations, till at length, by a natural series of incidents, he is finally brought to the discovery of his reputable descent, and is united to a beautiful heiress, of whom he was enamoured, and of whom the person he discovers to be his mother is the guardian. The thread, however, by which the hero is connected with the other characters of the work is very slight, and the incidents are barely such as keep up its title to the character of a regular novel. It is not distinguished by originality of sentiment, by novelty of character, by deep involution of events, or by scenes of complicated distress or unexpected deliverance. But, without deeply interesting the feelings, the mind is kept, particularly through the conversation pieces, in an agreeable state of amusement; and it is wonderful that, in its perusal, we should experience so little lassitude, when there is so little excitation.

Mordaunt possesses something of the same sort of merit as *Edward*, but in an inferior degree. A series of letters from different persons, characteristically supported, was a species of novel which required great versatility of powers, and one in which the genius of Dr Moore qualified him peculiarly to excel. But it would appear that the brilliancy of his wit had been tarnished by too frequent exposure to the world, or that his natural vivacity had been somewhat diminished by the advance of age. He survived the publication of *Mordaunt* only two years, and died at London in 1802.

The reputation of Dr Moore with posterity will rest on his travels and novels. As long as they are read, he will be acknowledged as a writer endued with admirable good sense, a rich vein of original humour, an uncommon power of insight into human nature, and a capacity of describing its intricacies with force and discernment. (M.)

MORAYSHIRE, or MURRAYSHIRE, a county in Scotland. The province of Moray formerly included part of the shires of Inverness and Banff, and that of Nairn, besides the present county; but the name is now confined to this district, which is also known by the appellation of Eginshire. It is situated between 57° 12' and 57° 43' north latitude, and between 3° 2' and 3° 58' west longitude, extending about 40 miles from north-east to south-west, and in breadth from 8 to 14 miles in the interior, but upon the coast from 17 to 23 miles; and it contains, including its lakes, 480 square miles, or 307,200 English acres, of which only about a third

is productive land. The county of Moray has the Morayshire. frith of that name on the north, Banffshire on the east, Inverness-shire on the south, and Nairnshire on the west. The river Spey, which, with a few exceptions, separates it from Banffshire, is commonly considered its eastern boundary. On the south, it is intersected by a small part of Inverness-shire, by which two parishes, Abernethy and Duthil, partly in county, are detached from the body of it. It is divided into fifteen entire parishes, and contains part nine parishes more, the rest of which are situated in the counties adjacent. The Presbyteries to which these parishes belong are, Aberlour, Abernethy, Elgin, and Forres, all under the jurisdiction of the Synod of Moray.

The natural divisions are the low grounds which Natural stretch along the coast, varying in breadth, southward, Divisions. from 5 to 12 miles, and the mountains which occupy the interior; yet the former is not without ridges of hills, of no great height, which generally rise in a line parallel to the shore; nor the latter without considerable tracts of low land, particularly on the branches of the Spey and Findhorn, and the other streams which flow from the south. The climate, soil, and productiveness of these two divisions are very different. The climate on the coast is supposed Climate. to be as good as that of any part of Scotland, both in respect to heat and dryness; while the prevailing soil is a sandy loam, in many parts affording plentiful crops, which ripen early, and are seldom injured by bad weather, in the harvest season. The wind blows from westerly points for almost three-fourths of the year. The strong gales are from the north-west, and the most frequent rains from this point and the north-north. Easterly winds, however, prevail in the spring months, to the great injury of vegetation. The annual fall of rain, on the north-east quarter, near Speymouth, is said to be little more than 25 inches; and the medium temperature of the year varies from 45° to 50°. In the mountain district, the winters are long and severe; more rain falls than on the coast; and the labours of the harvest are sometimes not brought to a close till the crops are covered with snow. Limestone, sandstone, and slate, with marl, abound in various parts. Iron was almost a century ago wrought in Strath-spey by the York Buildings Company. The rivers Rivers are the Spey, the Lossie, and the Findhorn, which receive the waters of a great many mountain streams. The Spey, the most considerable, has a course of 30 miles before it enters Morayshire, at Aviemore, from which it flows in a deep channel, and with a considerable fall, till it empties itself, after describing a line of about 96 miles in all, into the sea at Speymouth Bay. It is not navigable, except near its mouth, and there only for small vessels; but it affords the means of bringing down to the sea the forests on its banks; and the rents of its salmon fisheries, some years ago, exceeded £7000 per annum. The Lossie flows almost parallel to the Spey, about ten miles distant, and, after a course of 24 miles, during which it works a number of corn mills, falls into the sea at Lossiemouth, about six miles to the north of Elgin. The Findhorn, like the two former, flows from south to north, and enters the Frith of Moray at the village that bears its name, having

Situation
and Extent.

Morayshire. traversed Inverness-shire, where it has its source, Nairnshire, and this county, for a distance of 60 miles. There is also a valuable salmon fishery on this river. The principal lakes, beginning on the east, are Loughnaboe, which covers about 60 acres; Lough Spynie, which formerly spread over more than 2000 acres, but has been since laid almost dry by drainage; Inchstellie, Lochloy, and Loughnadurb, containing an island on which there are the remains of an ancient fortress, and where it is said turnips have been found growing naturally. Chalybeate springs are found in every quarter of the county, but none of them are in much repute.

Valuation and Rental The valued rent of Morayshire, in Scots money, is L.65,603, 0s. 5d., and the real rent, in 1811, of the lands was L.62,312, 9s. 6d. Sterling, and of the houses L.2,753, 14s. 6d. In the same year, the number of proprietors was forty-one, five of whom held more than half the valuation and rental; and that of the freeholders thirty-six. Only about a fortieth part is held in feu, the whole, with this exception, and small portions belonging to the burghs, being freehold, but nearly a third is under entail. Many of the proprietors have elegant mansions, of which the most considerable, beginning on the eastern quarter, are Innes House, the Earl of Fife; Findrossie, Lesslie, Bart.; Gordonstown and Altyre, Cumming Gordon, Bart.; Duffus, Dunbar, Bart.; Darnway Castle, the Earl of Moray; Brodie House, Brodie; Grange, Peterkin; Burgie Castle, Dunbar Brodie; and Elchies House, Grant.

Seats. The size of farms on the coast does not often exceed 400 acres, and the greater number are below 150 acres. The larger farms are generally held on leases for nineteen years, as in other parts of Scotland, but many of the smaller tenants have no leases. This division of the county produces all the species of corn grown in Scotland, with turnips, potatoes, and clovers. In the higher district, barley and oats, with potatoes, are almost the only crops, with small por-

Farms. tions of turnips and cultivated herbage, and in some places a little flax. The native cattle have been improved, by crossing them with the West Highland race; and the sheep, which were originally similar to those of Shetland, have, in many parts, given way to the Linton, or black-faced race, and a variety of other breeds from the south. On the small farms, especially in the mountain district, the horses are very diminutive, seldom more than nine or ten hands high; but, upon the larger farms on the coast, they are not inferior to those of other parts of Scotland. In the latter situation, two only are used at a plough, and oxen are seldom worked; whereas, the team in the high grounds consists of oxen and horses intermixed, sometimes to the number of six or eight.

Manuf. Morayshire employs few of its people in manufactures for sale. A woollen factory has been established at Newmill, in the parish of St Andrews Lhanbryd, and in the same quarter another for the weaving of cottons. There are tanneries at Forres and Elgin; and, at the latter place, a tawing work of some consideration, which sends most of its produce to London. The exports are cattle, corn, and salmon, with a variety of smaller articles. The value of the salmon has been stated at about L.25,000, and that of all the other exports does not exceed L.30,000 yearly. A considerable quantity of timber is floated down the Spey, and shipped at Garmouth; but it is chiefly the produce of Strathspey, in Inverness-shire. The towns and villages are, Elgin, the county town, Forres, Garmouth, Urquhart, Lossiemouth, Bishopmill, Findhorn, Rothes, and Balnatom. The first two are burghs; Elgin is joined with Cullen, Banff, Inverary, and Kintore; and Forres with Inverness, Nairn, and Fortrose, in the election of members for the Scottish burghs. Both these places are of great antiquity. The population in 1800 and 1811 is exhibited in the following abstract. See Leslie's *General View of the Agriculture, &c. of the Counties of Nairn and Moray.* (A.)

MORTALITY, HUMAN, LAW OF.

Mortality. THE law of human mortality is that which determines the proportion of the number of persons who die in any assigned period of life, or interval of age, out of a given number of persons who enter upon the same interval; and, consequently, the proportion of them who survive that interval.

Tables showing how many out of a great number of children, as 10,000, or 100,000, born alive, die in each year of their age; and, consequently, how many complete each year; exhibit this law through the whole extent of life, and are called *Tables of Mortality*.

For information respecting the *data* from which such tables may be constructed, and the uses they may be applied to, the reader is referred to the articles **BILLS OF MORTALITY** and **ANNUITIES**, in this *Supplement*.

There is already an article on this subject in the *Encyclopædia Britannica*, under the head **BILLS OF MORTALITY**; but the imperfections of that article, and the increasing importance of the subject, render it expedient that it should be resumed here, and treated entirely anew.

The present article is divided into three parts. In the *first*, we deliver the history of this branch of knowledge, with as much brevity as appears to be consistent with the chief object,—that of conveying correct and useful information.

In the *second part*, we demonstrate the whole theory by common arithmetic.

In the *third part*, a new table of mortality is given, constructed on the principles previously explained; some observations are made on the comparative merits of the different tables that have been published; which were purposely omitted in the historical part, when the tables they relate to were mentioned, to avoid discouraging such readers as might not be previously acquainted with the theory; and the faults are explained, which render most of those tables really of no use, since others, more correct, have been constructed.

PART I.—History.

The first table of mortality was constructed by Dr Halley, from the Mortuary Registers of Breslaw, for five years ending with 1691; and was inserted in his paper on the subject in the *Philosophical Transactions* for the year 1693, with many judicious observations on the useful purposes to which such tables may be applied.

No further information of this kind was communicated to the public, until William Kersseboom of the Hague published there three tracts on the subject (in 4to). The first, dated March 1, 1738, was entitled, *Eerste Verhandeling tot een Proeve om te weeten de probable menigte des volks in de provincie van Hollandt en Westvrieslandt*. The second, dated May 15, 1742, *Tweede Verhandeling bevestigende*

de Proeve om te weeten de probable meenigte des volks in de provincie van Hollandt en Westvrieslandt; and the third, dated August 31, 1742, *Derde Verhandeling over de probable meenigte des volks in de provincie van Hollandt en Westvrieslandt*. **Mortality.**

A good account of the first of these tracts has been given by Mr Eames, in the *Philosophical Transactions* for 1738; and rather a meagre one of the other two, by Mr Van Rixtel, in the same *Transactions* for 1743. It is therefore unnecessary to repeat here, any thing contained in those accounts; but as they give no satisfactory information concerning the construction of Mr Kersseboom's table of mortality (which he called a *Table of Vitality*), it will be proper to supply so material a defect in this place.

In his first tract, the author informs us that he constructed his table from registers of many thousand life annuitants, in Holland and West Friesland, which had been kept there from 125 to 130 years previous to the date of his publication; and showed how many of the nominees, or lives the annuities depended upon, were, at the time of their nomination, under one year old, between one and two, between two and three, and so on for all ages.

An exact account was also kept of the age at which each life of every class failed; whence it clearly appeared, what degree of mortality prevailed at every age above one year. But because very few children were nominated at or near their birth, he could not, from these registers, determine the mortality under one year of age. He therefore had recourse to mortuary registers and other observations; from exact accounts of which he found, with sufficient certainty (as he says), that out of 28,000 born alive, 5,500 died under one year. He also informs us, that, for this purpose, he made use of the observations of divers learned men in England and elsewhere, especially Major John Graunt's, upon the number of the people and the rate of mortality; and upon taking an average of the whole, he found it to differ but little from that just stated.

And this appears to be the only ground for the assertion made by most writers on this subject (probably copying from each other without having seen the original work), that Kersseboom's Table of Mortality was constructed from observations made upon annuitants in England as well as in Holland; also, that it was formed partly from observations made upon the inhabitants of some Dutch villages.

He first published his Table of Mortality in his second Tract, and in his third, he gave abstracts of the registers from which it was constructed;—these were contained in twenty-nine tables, twenty-two of which were for the two sexes separately; in the rest the sexes were not distinguished; and the ages at which the lives failed were generally given to the exactness of half a year.

Mortality. The numbers of lives, whose current year of age at the time of their nomination was given precisely in these tables, were,

Males separately, -	1848
Females separately, -	1769
Males and Females, without distinction of sex,	1536
Total,	5148

And none of these nominees were above 12 years of age at the time of their nomination.

These, however, are only specimens of Mr Kersseboom's labours. He says there were so many lives in the registers, that he had not the courage to undertake extracting the necessary particulars for more than 50,000 of them; and in that, he was greatly assisted by his friend Thomas von Schaak.

Of all the lives, not more than 1 of 120 was past 55 years of age at the time of nomination.

Nicholas Struyck, in his *Aanhangsel op de Gissengen over den staat van het Menschelyk Geslacht, en de Uitreekening der Lyfrenten*, published at Amsterdam in 1740, at the end of the quarto volume, commencing with his *Inleiding tot de Algemeene Geographie*, gave, from registers kept at Amsterdam for about thirty-five years, two tables of observations made upon the duration of the lives of 794 male, and 876 female annuitants separately; and two tables of mortality he had constructed from them for the two sexes; both beginning with five years of age. These two, taken together, differ but little from that of Dr Halley; they represent the mortality to be considerably greater than Kersseboom's: having been constructed from so few observations, they are not entitled to much confidence, and appear to have been very little known or attended to.

This work of Struyck gave occasion to the publication, in the same year, of a small tract (in 4to) by Kersseboom, entitled, *Eenige Anmerkingen op de Gissengen over den staat van het Menschelyk Geslacht, &c.*, wherein he accused Struyck of plagiarism, with but too much appearance of justice.

Neither Kersseboom nor Struyck gave any information as to the manner in which they formed their tables of mortality from the observations on which they were grounded. Mr Kersseboom informs us, that he submitted his table to Professor S' Gravesande, some years previous to its publication, and obtained his approbation of it for calculating the values of annuities on lives.

In the year 1742, Mr Thomas Simpson, in his *Doctrine of Annuities*, (see ART. ANNUITIES in this Supplement,) gave a table of mortality for London, being the same that had previously been constructed by Mr Smart, at twenty-five and all the greater ages, but corrected at all ages under twenty-five years, on account of the great number of strangers who settle in London under that age, which occasioned, till lately, a constant excess of the burials above the births. This correction Mr Simpson made by comparing together the numbers of christenings and burials; and observing, by means of Dr Halley's Table, the proportion between the mortality in London and Breslaw above twenty-five years of age.

In 1746, M. Deparcieux published (at Paris in 4to) his *Essai sur les Probabilités de la durée de la vie Humaine*, in which he gave six new and valuable tables of mortality; one of them constructed from the lists of the nominees in the French Tontines, principally those of the years 1689 and 1696, and the rest from the mortuary registers of different religious houses;—four of these showing the mortality that prevailed among the monks of different orders, and the fifth, that which obtained among the nuns in different convents of Paris. Those for the monks and nuns, with the exception of the tables of Struyck, mentioned above, were the first ever constructed for the two sexes separately.

The *Essay* of M. Deparcieux is written popularly, and with great perspicuity; he has given the most satisfactory accounts both of the data his tables were constructed from, and the manner of their construction.

In his thirteenth table, he included with the five tables of mortality of his own construction; that of Mr Smart for London, as corrected by Mr Simpson, Dr Halley's, and Mr Kersseboom's, together with the expectation of life at, or its average duration after each age, both according to his own and Mr Kersseboom's table for annuitants, and for every fifth year of age according to each of the other tables; the fractional parts of a year being always expressed in months, and not in decimals.

Dr Halley first, and Struyck after him, had given the *probable duration of life* after several ages, according to their respective tables, that is, the term at the expiration of which, the persons now living at any proposed age, will be reduced by death to one-half their present number.

But Deparcieux appears to have first given the *average duration of life* after any age, and showed how to calculate it correctly from tables of mortality. On account of the scarcity and value of M. Deparcieux's *Tables of Mortality*, Mr Milne has reprinted them, with the expectations of life just mentioned, in his *Treatise on Annuities*, with a short account of their construction; it is therefore unnecessary to pursue the subject further here.

M. de Buffon, at the end of the second volume of his *Histoire Naturelle*, published in 1749, inserted a table of mortality that had been constructed by M. Dupré de Saint Maur, from the registers of twelve country parishes in France, and three parishes of Paris; which M. de Buffon informs his readers that he inserted in his work the more willingly, since these were the only kind of documents, or combinations of them, from which the probabilities of life among mankind in general, could be determined with any certainty. Yet this was a very faulty table, and the numbers of annual deaths were so injudiciously distributed, according to the ages, that it often represented the mortality in one year of age to be three or four times as great, and in some cases, six times as great, as in the next year. Some remarks of M. Kersseboom on this table may be seen in the *Philosophical Transactions* for 1753. M. de Saint Cyran corrected some of its most obvious errors, and inserted both the original and his corrected copy in his *Calcul des Rentes Viageres*. (4to. Paris, 1779.)

Mortality. Mr Simpson, in the *Supplement* to his *Doctrine of Annuities*, published in 1752, gave some further explanations of the corrections he had made in Mr Smart's table of mortality for London; and made some very judicious observations on the difficulties that attend the construction of tables of mortality from the mortuary registers only, of large towns.

In the *Nouveau Mém. de l'Acad. Roy. de Berlin* for the year 1760, there is a paper by the celebrated Euler, entitled *Recherches générales sur la mortalité, et la multiplication du genre humain*, wherein the subject is treated algebraically. He assumes that the population is not affected by migration, and that the annual births and deaths are always as the contemporaneous population; consequently, that the number of the people increases or decreases in geometrical progression. Then he gives several theorems exhibiting the relations that would obtain between the annual births and deaths, and the population, and determines the law of mortality upon these hypotheses, but does not show how it may be deduced from actual observations independent of hypotheses; neither does he undertake the construction of any table of mortality, but, by way of example, gives that of M. Kerssboom, with the changes of the numbers which become necessary, in consequence of his altering the radix from 1400 annual births to 1000.

Süssmilch took great pains in collecting the numbers of annual deaths in the different intervals of age, which he published in his *Göttliche Ordnung*; and four tables of mortality formed from these data are to be found in the same work: that in the 2d volume (§ 461), which has many imperfections was formed by himself; the three others, being the 21st, 22d, and 23d, at the end of the 3d volume, were constructed by his commentator Baumann, according to the more correct method of Lambert.

The first edition of Dr Price's *Observations on Reversionary Payments* appeared in 1771, containing his observations on the proper method of constructing tables of mortality from bills which show the numbers dying annually at all ages (see the article **BILLS OF MORTALITY** in this *Supplement*, p. 311), and three new tables of mortality constructed from the London, Norwich, and Northampton bills.

The second edition of the same work was published in 1772; and contained, in the *Supplement*, much interesting and valuable information which did not appear in the first; with five new tables, intended to exhibit the law of mortality that obtained,—1. In the district of Vaud, Switzerland. 2. In a country parish in Brandenburg. 3. In the parish of Holy Cross, near Shrewsbury. 4. At Vienna. 5. At Berlin. The first formed from bills of mortality given in the *Mémoire* of M. Muret; and the 2d, 4th, and 5th, from those given by Süssmilch in his *Göttliche Ordnung*; the 3d was from the parish register only, of Holy Cross. And we consider none of those tables to be now of any value, on account of the defects in the data they were constructed from.

Mortality. At the end of the first volume of the work of J. H. Lambert, entitled, *Beiträge zum Gebrauche der Mathematik und deren Anwendung*, published at Berlin in 1765 (8vo), he gave a chapter *On the certainty of inferences deduced from observations and experiments*; and the example with which he concluded the illustration of his theory, was the deduction of the law of mortality in London from the bills of mortality there; by means of a curve, of which the absciss being proportional to the age, the corresponding ordinate was proportional to the number of survivors of the same age.

In the third volume of the same work, published in 1772, the ingenious author treated the subject at much greater length: x being the age, and y the corresponding ordinate to the curve of mortality for London, proportional to the number of survivors of that age out of a given number (10,000) born alive; he

gave this equation to the curve, $y = 10,000 \left(\frac{96-x}{96} \right)^x - 6176 \left(e^{-\frac{x}{13.682}} - e^{-\frac{x}{24.3114}} \right)$, (e being the num-

ber of which unit is the hyperbolic logarithm); which determined the numbers in the table of mortality very near the truth, until 96 years of age, beyond which it was not intended to be used.

M. Lambert also constructed a table by which he intended to exhibit the law of mortality that prevails among mankind in general, from the 23d and 24th tables in the second volume of Süssmilch's *Göttliche Ordnung*, which gave the numbers of deaths, in the different intervals of age, in seventeen country parishes in the mark of Brandenburg, and from the London bills for thirty years; supposing, with Süssmilch (*Göttl. Ordn. T. I. § 34*), that the country people are double the number of those residing in towns.

By an extract of a letter from M. Lambert to Gaeta and Fontana, given in their Italian translation of Demolivre's *Treatise on Life Annuities* (*Discorso Preliminare, Parte III.*), it appears, that all his attempts to find *à posteriori* an equation which should determine the relation between the age and the number of survivors in this last table, proved fruitless; the formulæ he arrived at having been either too long and intricate, or too incorrect. This is the less to be regretted, since there is no doubt that M. Lambert's table did not represent the true law of mortality, as he made no allowance for the effect of the increase of the people by procreation; and it is singular he did not see, that that law might be correctly determined from the numbers of the living, and the annual deaths at all ages in Sweden and Finland, given in Mr Wargentin's paper in the *Stockholm Transactions* for 1766; which paper he himself quotes.

Lambert appears to have first demonstrated clearly the principal properties of tables of mortality;* in doing which, he made use of the differential and integral calculus; but as he could not determine the

* The author thinks it right to observe here, that he did not see the above mentioned work of Lambert, until he procured it from the Continent in November 1819; and that he had published elementary alge-

Mortality. equation to the curve of mortality, that resource did not avail him much.

Florencourt treated this subject algebraically in the third chapter of his *Political Arithmetic**, where he gave a perspicuous view of it, as it had been previously treated by Euler and Lambert; but added nothing himself that was original, except three new tables of mortality; one for males, another for females, and a third for both sexes without distinction; deriving his data in each case from the *Göttliche Ordnung* of Süßmilch. He also gave a new copy of the table of mortality M. Deparcieux had constructed from the registers of the nominees in the French tontines; assuming 10,000 for the radix, and inserting the numbers under three years of age, nearly according to M. Kersseboom's table; this, however, does not differ materially from the original table of Deparcieux.

The fourth edition of Dr Price's *Observations on Reversionary Payments* was published in 1783, and contained new tables of mortality for Warrington and Chester, also for all Sweden and Finland, and for Stockholm separately, in which the sexes were distinguished; those for the whole kingdom were constructed from enumerations of the living, and registers of the annual deaths, in each interval of age, during twenty one years; those for Stockholm during nine years. These tables for Sweden and Stockholm were the first ever constructed from the data that are requisite to determine the law of mortality among the bulk of the people, and were sufficiently accurate representations of that law, for the times and places in which the observations were made.

In a paper of M. Henrik Nicander, inserted in the *Transactions of the Royal Academy of Sciences* at Stockholm, for the first quarter of the year 1801, he gave two tables of mortality for all Sweden and Finland, in which the sexes were distinguished, but they were not properly constructed; and the mean duration of life which he gave in them at each age, was very erroneous, especially in early life. In that paper he asserted, without offering any demonstration or proof, that, in what we have called the curve of mortality above, if an ordinate be drawn through the centre of gravity of the portion of the area cut off by the ordinate at any assigned age, on the side of the more advanced ages, the part of the base, or of the axe of the abscisses, intercepted between these two ordinates, will measure the mean duration of life after such assigned age. And the mean duration of life after each age, which he has given, was determined in this manner.

Mr Milne's *Treatise on Annuities and Assurances* was published in 1815; and, in the third chapter of that work, the construction and properties of tables of mortality are fully treated of.

In the second volume of the same work, three new tables of mortality are given; one constructed from very accurate observations made at Carlisle, by Dr

Heysham, who preserved the bills of mortality of the two parishes, which include that city and its environs, and supplied their deficiencies with great care, together with correct accounts of two enumerations of the inhabitants, in which their ages were taken. Except the Swedish registers and enumerations, this is the only instance in which the data requisite for the construction of an accurate table of mortality for the bulk of the population, have been obtained; and a table showing the diseases by which the deaths at all ages were occasioned, is also given.

The fourth and fifth tables in Mr Milne's work, exhibit the law of mortality which prevailed in all Sweden and Finland, both with and without distinction of the sexes, deduced from the registers kept and the enumerations made there, during the twenty years ended with 1795; which term was subsequent to that wherein the observations were made, from which Dr Price's tables were constructed.

The seventh table in the same work exhibits the law of mortality at Montpellier for males and females separately, and was constructed from the bills of mortality of that place for twenty-one years, ending in 1792.

PART II.—On the Construction and Properties of Tables of Mortality.

1. Suppose 10,000 children to have been all born alive at the same instant of time, more than 100 years since; and that the numbers of them who completed and who died in each year of age were correctly entered in the following table:

Age.	Number who	
	completed the year	died in the year next
0	10,000	858
1	8,142	53
2	7,079	250
3	7,103	177
4	7,026	130
5	7,096	112
...
...

...
90	49	15
91	34	11
92	23	9
93	14	5
94	9	4
95	5	2
96	3	1
97	2	1
98	1	1

braical demonstrations of the properties of tables of mortality, as well as of the best methods of constructing them, in March 1815.

* *Abhandlungen aus der Juristischen und Politischen Rechenkunst*, von Carl Chassot de Florencourt, Altenburg, 1781, 4to.

mortality. which, then, would evidently be a table of mortality; and this mode of constructing one, were it practicable, would be the simplest possible.

2. But of 10,000 children taken indiscriminately at birth, it is manifest that the number who complete or survive any year of age, will be just the same, whether they be all born at the same time or not; and, therefore, this table might as well have been constructed by noting the times of the births of 10,000 children taken indiscriminately, and registering the time or the age at which each died; for then, after the whole were extinct, it would only be necessary to collect the sum of those who died in each year of their age, and insert it in the third column of the above table (1) against the proper age. The numbers in the second column would then be obtained by beginning with the 10,000 births, and merely subtracting the number in the third from the number in the second column, and placing the remainder in the next line below, in that column, throughout the table.

3. It is evident that the number against any age in the second column of such a table is equal to the sum of those in the third column against that, and all the greater ages; that is to say, that *the number who complete any year of age is equal to the sum of those who die at all the greater ages.*

4. Now let us suppose the population of a place to have remained invariable for one or two hundred years past, during which period 10,000 children have been born alive, at 10,000 equal intervals of time in each year. And that there having been no migration, and the law of mortality having been always the same, both the number of the living and that of the annual deaths in each year of age, have remained constant, the whole amount of the annual deaths at all ages, as well as the number of annual births, having been 10,000.

5. Then, if the law of mortality exhibited in the above table (1) be that which obtains in the place just mentioned, that table will represent the stream of life which flows through it, and fills the vacancies left by those who advance in age, or are carried off by death, their successors incessantly following and being followed in the same course.

6. Thus:—10,000 children being born annually at so many equal intervals of time, 7096 will annually complete their fifth year, also at equal intervals; and of these, 112 will die annually in the sixth year of their age.

7. And it is manifest, that, *the number who annually complete any year of their age in such a place, is equal to the sum of the annual deaths at all the greater ages.*

8. Let us next suppose, that the constant number of deaths which happen annually in any one year of age, take place at equal intervals of age in that year. For instance, that the four deaths which happen annually, in the 94th year of age, always take place at the ages of

Years.	Months.
94	- 3
94	- 6
94	- 9

and 95 years; or rather, that the last individual dies at the moment before completing the 95th year.

9. Then the number constantly living in any year of age may be determined as follows:

Let us take, for example, the 94th year, which 14 persons annually enter upon, and 5 die in.

Now, if no deaths happened in that year, it is obvious that the 14 persons who annually enter upon it at so many equal intervals (4 and 6), would be all constantly living at 14 equal intervals of age in that year; and if that year of age were divided into five equal intervals, there would be constantly living in

each interval $\frac{14}{5}$ persons; or, in a place similarly circumstanced, but five times more populous, 14 persons.

But when five deaths take place at so many equal intervals in the 94th year of age; (the fifth part of a year being 73 days,) the case is altered:—Thus,

Lives.	Complete the Age of		Number of the Living during these last 73 Days.
	Year.	Days.	
14	93	73	14
13	94	146	13
12	93	219	12
11	93	292	11
10	94	—	10

Now, the oldest life that fails in the 94th year, must be considered to expire the moment before completing that year, as only 9 survive 94.

But the numerators of these fractions being in arithmetical progression, their sum is equal to half the sum of the first and last terms multiplied by the

number of terms; or $\frac{14+10}{2} \times 5$: which sum being

divided by the common denominator, 5; we have the

number of the living in the 94th year of age $= \frac{14+10}{2}$;

an arithmetical mean proportional between the numbers who enter upon the first and last of the intervals which that year of age was divided into.

10. Now the number, 9, who survive their 94th year, is less only by unit than the number 10, who enter upon the last of the intervals that year was di-

vided into; so that if, instead of $\frac{14+10}{2}$, we take

$\frac{14+9}{2}$, or an arithmetical mean proportional be-

tween the numbers who annually enter upon, and annually survive their 94th year, for the number constantly living in that year, it will only be less by half a life than what has just been demonstrated to be the true number, according to the hypotheses; and the difference would still have been but half a life, although the radix of the table had been 10,000,000 instead of 10,000; the number of the living would, in that case, according to these two methods, have been 1200 and 1199½. And the number of the living

Mortality. in any one year of age, even according to the above table, is generally several thousands; so that this difference, which remains always the same, is quite immaterial.

Besides, it is obvious that the above hypotheses can never coincide exactly with the facts. And the above reasoning is evidently applicable to any other year of age.

11. We are therefore authorized to conclude, that, in a place circumstanced as above stated, *the number of the living in any year of their age, is an arithmetical mean proportional between the numbers who annually enter upon, and who annually complete that year.*

12. Thus it appears that

The number of the living in their	Is half the sum of
94th year,	14 and 9,
95th ———	9 and 5,
96th ———	5 and 3,
97th ———	3 and 2,
98th ———	2 and 1,
99th ———	1 and 0.

But it is to be observed, that the same numbers occur in the first of these two series as in the second, except the first term of the first, and the last of the second, which are 14 and 0 respectively. Therefore the sum of the second of these two series falls short of the sum of the first, by 14, the number who annually complete their 93d year; so that the series of half sums falls short of the sum of the first series by 7, the half of 14. And this reasoning will apply equally to any other age than that of 93 years.

13. Whence it follows, that, in a place circumstanced as we have supposed, *the number of persons constantly living at any assigned age and upwards, is less than the sum of those who annually complete that and all the greater ages, by half the number who annually complete that year of their age.*

14. From the supposition that the number of persons who die annually in any one and the same year of age, expire at so many equal intervals of age in that year (8), it follows, that, for each of these lives which fails before the middle of that year of age, there will be another which will fail just so much after it; and, consequently, that the average quantity of existence during any year of age, for the lives that fail in it, is just half a year.

15. But in taking, for any one year of age, the sum of the numbers in the second column of the table (1) at all the greater ages, each life is counted once for every complete year it survives, after the age first mentioned; and if, to the sum of these, we add half the number in the same second column against that first mentioned age, this half number being the sum of the fractional parts of a year, by which the whole of these lives survive the last year of age they complete (14); the sum total thus obtained, will evidently be the whole duration of life after the age first mentioned, enjoyed by all the lives that survive that age in any one year.

16. Therefore, if this last sum total be divided by

Mortality. the number who annually survive that first mentioned age, the quotient will be *the mean duration of life after that age*; which is also called *the expectation of life at the same age*, being the portion of future existence which an individual at that age may reasonably expect to enjoy.

17. But, by No. 13 it appears, that the last mentioned sum total is also the number constantly living in the place, at and above the age first mentioned (15).

18. Whence, and from No. 16, it follows, that if the number of the living in the place at any age and upwards, be divided by the number who annually complete that age, the quotient will be the mean duration of life after the same age.

19. And, consequently, if the number constantly living at all ages, be divided by the number of annual births, the quotient will be the mean duration of life from birth, or the expectation of life of a child just born.

20. Hence also it appears, that the number of years in the expectation of life at any age, is the same as the number of living persons at that age and upwards, out of which one dies annually.

21. Thus, for example, the expectation of life at 40 years of age being 25.495 years, the proportion of the living in the place aged 40 years and upwards who die annually, is one of 25.495, or, which is the same, 1000 out of 25,495.

22. The numbers represented by a table of mortality to die in any intervals of age, are called *the decrements of life* in those intervals.

23. And the interval between any age and the utmost extent of life, according to any table of mortality, is called *the complement of life* at that age, according to the same table.

24. If the decrements of life be supposed to be equal and uniform through its whole extent, and the interval between birth and the utmost extremity of life be divided into as many equal parts as there are annual births; then, one of the individuals born, will die at the expiration of each of these equal intervals of age; and the numbers who survive the several intervals, from birth to the extremity of life, will form an arithmetical progression.

25. Whence it will be found (11), that the number of the living at any assigned age and upwards, will be equal to the number who annually complete that age, multiplied by half the number of years in the complement of life at the same age.

26. And if this last product be divided by the number who annually complete that age, the quotient, that is, *half the complement of life, will be the expectation of life at that age* (18).

27. The mean numbers of annual deaths at all ages, or, which in this case is the same, the number of deaths in each year of age, that take place during any one year in a place circumstanced as we have supposed, being given, a table may be constructed as follows, which will answer all the most interesting questions that can be put respecting the population and mortality of the place.

28. Let there be five columns; in the first of which insert the ages 0, 1, 2, 3, 4..... 96, 97, 98, 99, and against every age, insert in the fifth column, the given number that died in the year

Mortality. between that and the next greater age; then begin at the greatest age, and proceed towards the least, as follows :

1st, To the number against any age in the fourth column, add that against the next less age in the fifth, and insert the sum against that next less age in the fourth (7).

2d, To the sum of the numbers in the third and fourth columns against any age, add half the number in the fifth column against the next less age, and insert this last sum against that next less age in the third column (11).

3d, Divide the number against any age in the third column, by the number against the same age in the fourth, the quotient will be the expectation of life at that age, to be inserted in the second column (16).

1.	2.	3.	4.	5.
Age.	Expectation of Life at that Age.	Number of the Living at that Age, and upwards.	Number who annually complete that Year of their Age.	Number who die annually in their next Year.

A complete table of this kind for the two sexes separately, formed from observations made in all Sweden and Finland, during twenty years ending with 1795, will be found in Mr Milne's *Treatise on Annuities and Assurances*, being the fourth in that work.

29. Hitherto we have supposed the state of the population to continue invariable for 100 years at the least, on account of the facility with which tables of mortality might be formed from accurate mortuary registers in such circumstances.

But whether the population be stationary or increasing or decreasing, and from whatever causes these changes proceed, provided that they be produced gradually, and not by sudden starts during the time of the observations, the law of mortality may be determined from actual enumerations of the people, and the bills of mortality, thus :

30. Let the number of persons in each year of

their age, that are resident in a place at any one time, be taken, and let an accurate register be kept of the number that die annually in each year of their age, during a term of eight or ten years at the least, whereof the first half may precede, and the second follow the time of the enumeration.

Then, if the number of the inhabitants of every age either increase or decrease uniformly during that term, the mean number of annual deaths in each year of age thus registered, will be the same as if the population of the place had continued throughout that term what it was when the enumeration was made.

31. But if, to the number of the living in any year of age, we add half the number who annually die in the same year, the sum will be the number who annually enter upon that year of their age (11).

And thus, from the enumerations and registers above mentioned, may be derived the ratio of the number who annually enter upon any year of their age, to the number who annually die in it.

32. But all the observations which have been made with sufficient minuteness, on the mortality during the first year from birth, concur in showing, that many more deaths take place in the first few weeks from birth, than in equal periods of time during the remainder of the first year; and that the nearer to birth, the greater is the mortality among infants. So that the number of the living in successive equal intervals in the first year of age, cannot be correctly assumed to be in arithmetical progression.

33. On this account it is desirable that the annual numbers, both of the children born alive, and the deaths under one year of age, should be correctly registered, as in Sweden.

34. Then, as the number annually born alive, is to the number of annual deaths under one year of age, according to the registers, so is the radix of the table of mortality, to the number dying under one year of age according to that table, which, being subtracted from the radix, the remainder is the number who complete their first and enter on their second year. Whence the numbers, both of survivors and annual deaths, at all the greater ages, may be determined in the order of their succession by No. 31.

35. If, instead of the number of the living in each year of age being taken only once, according to No. 30, that operation be performed several times during the term for which the mean number of annual deaths in each year of age is given;—then, the mean number of the living in each year of age throughout that term, must be deduced from the given numbers; and, being substituted for the number at the middle of the term according to No. 30, the law of mortality may be determined with more certainty, than when the people are only numbered once.

36. Both in enumerations of the people, and in bills of mortality, the numbers are, however, almost always given only for intervals of age of several years each. For the manner of interpolating the numbers in each particular year of age, the reader is referred to Mr Milne's *Treatise on Annuities and Assurances*, Arts. 180 and 181.

Mortality.

Mortality.

PART III.—On the Law of Mortality as deduced by the preceding methods from actual observations; and on the comparative merits of the different Tables of Mortality that have been published.

37. When the uniformity of anatomical structure in different individuals of the human species is considered, and the great power possessed by the human body, of so adapting itself to the circumstances it is placed in, as to avoid injury from changes in those circumstances, it will appear natural to expect, *a priori*, that, where the circumstances of the people are not greatly different, the law of mortality will be nearly the same. And, from a comparison of the best tables of mortality yet constructed, we are induced to believe that this expectation will be realized, whenever a sufficient number of good observations shall have been made, under circumstances sufficiently varied.

38. Hitherto, no observations have been made from which the law of mortality may be correctly determined, except

1. Those of Kersseboom, in Holland.
2. Deparcieux's, in France.
3. The Swedish.
4. Dr Heysham's, at Carlisle.

Those of Kersseboom and Deparcieux were made only on select classes of the people; the Swedish are incomparably the most numerous and extensive; but Dr Heysham's will, we believe, be found to be best authenticated, and most correct.

39. The climate of Sweden is so unfavourable to the products of agriculture, and the number of the people is so great in proportion to the quantity of food produced, that unfavourable seasons there, are generally followed by distressing dearths, and the destructive epidemical diseases constantly attendant upon famine, which raise the mortality, when they occur, much above what it would otherwise be; and both in that way, and by weakening the constitutions of those who survive them, they materially increase the average mortality deduced from observations made during any considerable number of years. Of this the reader will find ample proofs drawn from authentic sources, in the 10th, 12th, and 13th chapters of Mr Milne's *Treatise on Annuities*.

40. For these reasons, the mortality in Sweden deduced from many years' observations, will be found to be higher than in the more temperate and fruitful parts of Europe. And we shall probably make the nearest approach to the general law of human mortality in the temperate climates, that can be made from the Swedish observations, by selecting a period in which no remarkable epidemics prevailed. Such a period was that of five years commencing with 1801 and ending with 1805; during which, according to a statement of M. Nicander, in the *Transactions of the Royal Academy of Sciences at Stockholm* for the year 1809, the population and mortality were as stated in Table I. at the end of this article.

41. From these data, the second table, at the end of this article, has been formed. The numbers in the columns for males and females separately, having been determined according to Nos. 36 and 31—35; assuming that, of 20,000 children born alive, 10,219

are males, and 9,781 females, in the ratio of 275,599 to 263,812. Mortality.

The numbers against each age in the columns for the whole population without distinction of sex, are arithmetical mean proportionals between the corresponding numbers in the columns for males and females separately, against the same age.

42. From the table last-mentioned, Table III. has been deduced by No. 16, exhibiting the expectation of life at every fifth year of age; or its mean duration after that age.

43. Vaccination commenced throughout Sweden and Finland in 1804, during which year, the number vaccinated was 38,255; and, in the year following, 42,839.

The number of deaths by small-pox there, during the year

1801,	was	6,458
1802,	—	2,679
1803,	—	8,610
1804,	—	3,764
1805,	—	1,887

Sum, 23,398

Annual average number, 4,680

While the annual average of the ten years ending with 1803, was 6962. (*Vet. Ac. Handl.* 1809, and Milne *On Annuities*, Art. 698.)

44. Therefore if we assume that, had vaccination not been practised in the years 1804 and 1805, the annual average number of deaths during the five years ending with that last-mentioned, would have been greater by 2,282 than it actually was, and that these 2,282 additional deaths would have all taken place under five years of age, both assumptions will be near the truth; and it will follow, that the annual mortality under five years of age, which actually was but one of 13,534, would have been one of 12,629, had vaccination not been introduced. Its introduction cannot have affected the three first tables above five years of age; and under that age, not quite so much as has just been stated.

45. Of all ages, and both sexes, there actually died annually, during these five years, one of 40,901; had vaccination not been practised at all, the annual average mortality would not have been so great as one of 39,759.

46. Table IV. exhibits the mean duration of life after every fifth year of age, according to twelve different tables of mortality; the first six, A, B, C, D, E, F, having been constructed from the requisite data (30 and 38), the last six, M, N, O, P, Q, R, from mortuary registers only.

47. Of the first six tables, Kersseboom's (C), although constructed from great numbers of accurate observations, is entitled to less confidence than the rest, as he did not explain how he constructed it. If we knew it had been properly formed, it would afford ground to conclude, that until about 45 or 50 years of age, Holland was less favourable to the duration of human life than the rest of Europe, but not afterwards.

48. Deparcieux's Table (B), constructed from

mortality. great numbers of accurate observations on the nominees in the French Tontines, resident principally in Paris and its environs, represents the duration of life too small after 60 or 65 years of age. (See Mr Milne's *Treatise on Annuities*, Articles 867 and 868.)

49. Column D has been taken from the 45th Table in Dr Price's *Observations*, E from the 5th in Mr Milne's *Annuities*, and F from the 3d Table in this article. All these tables represent the duration of life in Sweden and Finland, after 45 or 50 years of age, to be less than according to the others; and it might reasonably be expected, *a priori*, that the excessive cold in Sweden would be unfavourable to the prolongation of life in old age.

50. Of the less correct columns, M has been deduced from the 7th Table in Mr Milne's *Annuities*, and N from the 42d in Dr Price's *Observations*; but, as the Montpellier and Chester Tables, just referred to, give the expectations of life only for males and females separately, the numbers in columns M and N against each age, are arithmetical mean proportionals between the expectations for males and females against the same ages in those tables; which, though not quite correct, is fully sufficient for our present purpose.

51. Column O has been derived from Lambert's Table for mankind in general, already mentioned in the historical part of this article, in which he gives a column headed *mean age*; thus, against the age of 20 in that column, stands 54.3; by which he means that persons who survive 20 years of age, do, on an average, attain the age of 54.3 years; so that their expectation of life at 20, will be 34.3. But his numbers in that column are all too great by $\frac{1}{2}$, or 0.5, as he has himself demonstrated; the last, therefore, should be 33.8; and

Against the Age of	For his Number.	We insert in Column O.
0	29.5	29.00
5	47.7	42.20
10	51.4	40.90
15	53.1	37.60
and so on.		

52. The reason assigned by Lambert for voluntarily admitting this error at each age, as well as the corresponding one in the number of the living at and above the same age, into his table, was, that he did not consider the *data* in his possession enabled him to determine the duration of life within half a year of the truth.

53. In both these errors M. Lambert has been followed by J. C. Baumann, in constructing the 21st, 22d, and 23d tables inserted at the end of the third volume of Süssmilch's *Göttl. Ordn.* which were intended to represent respectively, the law of mortality among the country people in the churchmark of Brandenburg, among the whole population of the churchmark, and among the inhabitants of London.

54. Column P has been taken from the 4th table in the above mentioned work of Florencourt, which was also intended to represent the law of mortality

among mankind in general, and was constructed partly from the registers of the same seventeen country parishes as that of Lambert, but instead of combining them with the London bills only, Florencourt also used those of Paris, Vienna, Berlin, and Brunswick; all given in Süssmilch's second volume; assuming also that the inhabitants of the country are to those of large towns as two to one. He determined the expectations of life according to the correct method, but not with much care or accuracy; for there are several numerical errors in that table.

55. The numbers in column Q were calculated by Deparcieux from Dr Halley's table; and those in column R have been extracted from the 18th table in Dr Price's *Observations*.

56. Upon comparing the numbers in the first six of these columns, which are more correct, with those in the last six, which are less so; it will be found, that at the early periods of life, its future mean duration according to the tables formed from mortuary registers alone, is less than according to those formed from the requisite *data*; also that the difference is greater the younger the lives are, and diminishes while the age increases, so as at 60 or 65 years of age to be little or nothing, and to continue small, and variable both in kind and magnitude, through the rest of life.

57. This appears to have arisen from the number of the people having varied but little during the first 35 or 40 years of the century that ended at or about the middle of the term in which the observations were made; and having increased considerably by procreation, during the remainder of that century; such increase having been slow at first, but gradually accelerated afterwards.

58. Table V. is calculated to illustrate this part of the subject. The columns A and B represent the law of mortality among the whole population of Sweden and Finland without distinction of sex, having been merely copied from Table II.

Column C shows the proportion of 10,000 annual deaths in Sweden and Finland that took place in each year of age, on an average of five years ending with 1805. And the number in column D against any age, being the sum of those in column C against that and all the greater ages, would be the number who annually attain to that age, if the number of the people of every age had remained stationary from the year 1700 till 1806 (7).

59. The table of mortality formed by the columns C and D therefore, is that which Dupré de Saint Maur, Süssmilch, Lambert, Baumann, and Florencourt, for want of the mortuary registers of a whole country, endeavoured to form by combining the registers of different town and country parishes.

60. But it has been ascertained by repeated enumerations of the people in Sweden and Finland, that the hypothesis of their number having remained stationary for the last 100 years or more, is far from the truth. And by comparing columns A and B with C and D, it will be seen in what manner, and to what degree, the falsity of the hypothesis in this case, has vitiated the table derived from it.

61. To facilitate this comparison, columns E and F have been added. Taking the age of five years

Mortality.

Mortality. for an example; the numbers against that age in columns C and D show, that, according to the hypothesis, out of 5988 children who annually enter upon their 6th year, 144 die in it; while it appears by columns A and B, that out of 7096 children who enter upon that year of their age, only 112 die in it: and $112 : 7096 :: 144 : 9123$, so that 9123, inserted against the age of five years in column E, is the number of children annually entering upon their 6th year, out of whom 144 *really* die in the same year of their age; and the mortality as represented by the hypothetical table in this case, is to the true mortality, as 9123 to 5988, or as 8 to 2 nearly.

Then the number in column F against any age, is always the excess of that in E above that in column D against the same age.

62. Columns B and C both containing 10,000 deaths, it will be seen that in column C, they are greatly accumulated at the early ages, in comparison with those in column B; and that in old age, the deaths in column C are much less numerous than in B; which are necessary consequences of the people increasing by procreation; the numbers of the people in a progressive population, in comparison with a stationary one, being greater in early life, and less in old age: And, while the law of mortality remains the same, the numbers of deaths at the different ages, must necessarily be distributed in a similar manner.

63. Neglecting those who survived 100 years of age, as inconsiderable in comparison with the rest. If the number of annual births in Sweden and Finland had remained stationary from the year 1700 till 1735, all that were born in that interval, would, during the term of our observations, have been between 65 and 100 years of age; and, if the law of mortality had remained invariable, the numbers in columns C and D, in Table V., would, during that period of life, have been exactly the same as those in columns B and A respectively against the same age; and the number in column F against each of those ages would have vanished, or been reduced to nothing.

64. But if the population and annual births had decreased a little from 1700 till 1735; then, the true and hypothetical laws of mortality, after 65 years of age in this table, would have differed the opposite way to what they do in early life; and the numbers in column F, after 65, would all have been negative.

65. Lastly, If the number of annual births from 1700 till 1735 varied but little, having sometimes increased and sometimes decreased, the differences of the tables, and the numbers in column F, after 65 years of age, would be such as we find them.

66. Table VI., which needs no further explanation than is placed at the head of it, will also illustrate the difference between tables of mortality formed from the requisite data, and those constructed from mortuary registers only.

It is better fitted for this purpose than Table IV., with which, however, it will be found to correspond very well. But the 4th Table has other uses which this has not.

67. From what has already been advanced, it

would appear probable, that the number of annual births in Sweden and Finland had been nearly stationary, and rather decreasing than increasing, upon an average, from about 1700 till 1735.

The numbers both of the annual births and deaths, from the year 1749 till 1803, will be found in Mr Milne's *Treatise on Annuities*, Art. 698: these kind of returns to Government were not made before 1749, neither have we any satisfactory account of the population before that period.

68. But the statements in our 7th table corroborate the inferences just drawn from the 5th and 6th, as they show that during the 43 years ended with 1800, the total population increased, while the proportion above 90 years of age diminished through the whole term, and increased very little during the next ten years.

The numbers in that table include both sexes, and the long continued diminution of them past 90, cannot be explained by supposing the males to have fallen in battle; for the females were reduced in the same proportion, their number throughout, having been to that of the males above 90 years of age, as nine to five nearly.

From the 7th table, therefore, it appears probable, that the annual births in the years

1698, 1705, 1710, and 1715,

were respectively proportional to the numbers

907, 637, 837, and 786.

The last number, 786, has been calculated upon the supposition that the proportion of the population in Sweden and Finland to those in Sweden alone, was the same in 1810 as in 1805.

69. It should also be observed here, that the disastrous career of Charles the Twelfth commenced with the eighteenth century, and terminated in 1718, when the country was in such a state of exhaustion as it could not have recovered from for many years; whence there appears reason to believe, that the annual births during the succeeding fifteen or twenty years, did not increase fast.

Cantzlaer informs us, that between the 10th August 1710, and the month of February 1711, near 30,000 persons were carried off by the plague in Stockholm alone. (*Mem. du Royaume de Suede*, T. I. p. 29.)

70. It will be seen that the numbers in col. F of Table V., in proceeding back from four years of age to birth, continually decrease, contrary to what generally obtains; and as we ascribed the general increase of these numbers, when taken in the retrograde order of the ages, to the annually increasing number of births, so will this anomalous appearance be found to arise partly from the average number of annual births having actually *decreased* for a few years; for

During the Five Years ending with	The Annual Average Number of Births was
1800	107,690
1801	106,392
1802	105,504
1803	104,644
1804	105,430
1805	107,882

But it appears to have arisen principally from the practice of vaccination during the years 1804 and 1805, by which the mortality among children, or the numbers in col. C, in a few of the first years from birth, were reduced below what they otherwise would have been (44), while those in col. D remained nearly the same (58); consequently, the numbers in col. E were reduced in nearly the same ratio as those in C (61), and the reduction in col. F was in each case nearly the same as in E (61).

71. The numbers relating to Sweden and Finland in the 7th Table, have been derived from the *Stockholm Transactions* for the years 1766, 1801, 1809, and 1813.

Those relating to Spain and the Spanish possessions in Europe and Africa, including the Canary Islands, from the *Censo de la Poblacion de Espana en el ano de 1797*, mentioned in the Article BILLS OF MORTALITY in this *Supplement*. These last have been included in this Table, to show the difference in the proportion of aged persons in Spain and Sweden, and still more between the Canary Islands and both.

72. If the population of Spain had remained invariable from 1697 to 1797, the law of mortality there, might have been easily derived from the statements above mentioned of the enumeration in 1797; but in the actual state of things, that cannot be determined without comparing these with exact accounts of the numbers that died annually in each interval of age. And the author avails himself of this opportunity to state, that, since the Article BILLS OF MORTALITY was printed, he has obtained satisfactory information that no such returns from the parish registers throughout Spain, as are there mentioned, ever were published, nor is it probable they were ever made.

73. When what we have advanced respecting the 5th and 6th Tables is clearly understood, it will not be difficult to account for the greater part of the difference between the more and less correct columns in Table IV.

Most of the observations which the German tables were constructed from, were made between the years 1720 and 1750; and those who died then between 60 and 100 years of age, must have been born between 1620 and 1690; in which period nearly the whole of the thirty years' war, ended in 1648, was included, during which, and for several years after, it is probable that the annual births increased little or nothing, if they did not decrease.

74. Among the less correct columns of Table IV., those for Montpellier and Chester agree much better than the rest with the more correct ones, which has probably arisen in each case, partly from the mortality in these two places having really been less throughout life than in most large towns; and partly from the annual births in them, having increased less than in the other places, during the fifty or sixty years preceding the period in which the observations the tables were constructed from were made.

75. The Northampton Table was constructed by Dr Price, from the bills of mortality (from the year 1735 to 1780) of the single parish of All Saints, containing a little more than half the inhabitants of

the town; and as the deaths exceeded the births in number, the Doctor applied a correction to the table under twenty years of age, which, if it had answered the intended purpose under that age, as we are satisfied it did not, could have no effect on any of the numbers above the same age; and almost all the useful applications of such tables, are to ages above twenty.

76. The table so formed could only be correct, provided that the numbers, both of the living and the annual deaths at every age above twenty years, had continued invariable during the 146 years that intervened between 1634 and 1780; provided also, that no migration from or to the town took place, except at twenty years of age, and that the annual increase the population received by migration at that age, was just equal to the excess of the annual deaths above the annual births.

77. But we consider it to be much more probable, that during these 146 years, Northampton partook of the prosperity and adversity that prevailed in the rest of the kingdom; and, consequently, that its population was generally progressive, though sometimes stationary, and sometimes retrograde.

78. We have not room here to support this opinion by numerical statements and calculations, but from the population abstracts, and an enumeration of the inhabitants of Northampton, given in Dr Price's *Observations on Reversionary Payments*, Vol. II. p. 94, it will be found, that both the annual births, and annual settlers in that town, have been increasing ever since about the year 1715 or 1720; also, that although the burials exceeded the baptisms till the year 1802, the supply by migration was much greater than that excess; and, consequently, that the numbers of the living have been accumulated more at the early ages, and less at the advanced ones, than they would have been had the population remained stationary.

79. Thus it appears, that the faults in the Northampton Table are of the same kind as those of the others constructed from mortuary registers only. And the civil war in the time of Charles the First, with the unsettled state of the kingdom for some years before and after it, would probably have prevented, or greatly retarded, the increase of the annual births, during the time in which those persons were born, who died past sixty years of age between the years 1734 and 1781, and may account for the table after that age, being near the truth; while the comparatively rapid increase of the people during the sixty years ending with 1780, appears to explain the great excess of mortality in that table at the early periods of life.

80. As it is only from the Carlisle and Northampton Tables of Mortality, that tables of the values of annuities on single and joint lives have been calculated, sufficiently copious to admit of the values of interests dependent upon the continuance or the failure of human life being accurately derived from them; we will here give, at one view, a comparison between the mortality represented by each of these tables to take place at the different periods of life, with that which has been observed to obtain among the members of the Equitable Assurance Society.

Mortality. 81. From an address delivered at a general court of that society by Mr Morgan the Actuary, on the 24th of April 1800, it appears, that, according to the result of an annual experience of thirty years, the decrements of life (22) among the members of the society, were to those in the Northampton Table,

Between the ages of 10 and 20	as 1 to 2
20 — 30	— 1 — 2
30 — 40	— 3 — 5
40 — 50	— 3 — 5
50 — 60	— 5 — 7
60 — 80	— 4 — 5

The same information may also be found in two notes in Dr Price's *Observations on Reversionary Payments*, Vol. I. p. 183, and Vol. II. p. 443, by which it also appears, that the number of lives this experience was derived from, exceeded 83,000.

82. From the preceding statement, the Carlisle Table of Mortality (No. II. in Mr Milne's *Annuities*, or No. V. at the end of the article *ANNUITIES* in this *Supplement*), and the Northampton Table (No. XVII. in Dr Price's *Observations*), we have derived the following.

Out of	Who attain the Age of	There die before the Age of	According to the		
			Carlisle Table.	Experience of the Equitable Society.	Northampton Table.
<i>Persons.</i>	<i>Years.</i>				
6460	10	20	370	309	618
6090	20	30	448	443	886
5642	30	40	567	579	965
5075	40	50	678	652	1086
4397	50	60	754	900	1260
3643	60	80	2690	2244	2805

83. This Table shows, that the law of mortality exhibited in the Carlisle Table is almost exactly the same as that which has prevailed among the members of the Equitable Assurance Society. And although the members of such a society, when they first enter, are select lives, they are not, even then, so much better than the common average, as many persons suppose; for the more precarious a life is,

the stronger is the inducement for parties interested in its continuance, to get it insured, so that bad risks are frequently offered to such companies. And many proposals for insurance are accepted by the directors, that are not thought very eligible at the time, in cases where they are not aware of any specific objection to the life proposed.

84. Besides, it is to be considered, that of the number in a society at any one time, but a small proportion can have been recently admitted, and in a few years from the time of admission, the members will generally have come down to the common average of persons of the same ages.

85. It ought also to be observed, that most of the tables of mortality that have been published, have been constructed from observations made upon the whole population of very large towns, such as London, Paris, Vienna, and Stockholm; in each of which there are particular quarters inhabited only by the very lowest of the people, who, unfortunately, are also very numerous, badly clothed and fed, therefore exposed to serious injury from the inclemencies of the weather; extremely ignorant and vicious, indulging in the abuse of spirituous liquors, and inattentive to cleanliness both in their persons and habitations; which last are crowded, badly ventilated, and surrounded with mud and the putrid remains of animals and vegetables. These are the nests of contagious diseases, in which they are generated and kept alive, where they at all times occasion great mortality, though not so much within the last 30 or 40 years as previously, and from which, when circumstances favour them, they spread among the rest of the people.

86. It is, therefore, obvious, that in such places, the average mortality at every age must be considerably greater than that which prevails only among the middling and higher classes of society even in such towns.

87. But the lives upon which leases, annuities, reversions, and assurances depend, are very seldom exposed to the influence of the causes of mortality mentioned in No. 85. Whence it follows, that a table of mortality on which those causes have had no great influence, is best adapted to the valuation of such interests.

And these kind of valuations are the most important purposes to which tables of mortality can be applied. (v.)

MORTALITY.

Mortality.

555

Mortality.

TABLE I.

In all Sweden and Finland during the Five Years ending with 1805.

Between the Ages of	Mean Number of the Living.		Annual average Number of Deaths.		That is, Males One of	That is, Females One of
	Males.	Females.	Males.	Females.		
0 and 1	44,536	43,847	11,132	9,238	4.00	4.74

(u.)

Mueller.

MUELLER (JOHANNES VON), the only author whom Germany can oppose to the illustrious historians of Italy and Britain, was born at Schaffhausen in 1752, of which town his father was a pastor. In 1769, he commenced his academical life at Göttingen, where he applied himself principally to theology; a study and a profession which he soon deserted. In 1772, he was appointed professor of the Greek language in the Gymnasium of his native town. In 1774, he removed to Geneva, where he principally resided till 1781. Here he delivered his lectures on Universal History, which were written originally in French; and here he formed the plan, and commenced the investigations towards his *History of the Helvetic Confederacy*. In 1781, he was called as professor of history to the Carolinum of Brunswick, an appointment which he soon abandoned; and, in 1782, he returned to Switzerland. By Heyne's recommendation, he was, in 1786, called as Librarian, with the title of Aulic Counsellor to Mentz. In 1800, he received the appointment of Librarian to the Imperial Library at Vienna; in 1804, was

called as Historiographer and Counsellor of War to Berlin; and, in 1807, was appointed Minister, Counsellor of State, and General Director of Public Instruction in Cassel. Here he died in 1809.

To enter into any detail regarding the history of Mueller's life is here the less requisite, as there perhaps never existed an author whose internal character was more independent of outward circumstances, or in whom the writer was in a more remarkable manner distinguished from the man; while, at the same time, his writings breathe the whole energy of the deep feelings of his ardent disposition. An honest enthusiasm for truth and virtue was combined in him, with an ambition, which could be satisfied only with the renown of a great author. No exertion of intellect was for him too painful; no perseverance in industry surpassed his endurance. Of a cheerful disposition, even amid the adversities of life, he pursued without faltering his determined object. From the letters which in his youth he wrote to his friend De Bonstetten, we see him at the beginning, the same as at the termination of his course. But this very con-

Mueller.

Mueller.

sistency renders the contrast between the two characters which he united in his person, only the more remarkable. By nature amiable, but soft even to weakness, open and liberal, though without one conspicuous trait of magnanimity, accommodating himself to circumstances with the pliability of a courtier, and yielding to the seduction of his passions in a point where morality condemns him without appeal: yet, no sooner had he seized his pen—no sooner had he begun to narrate the great events of former times, than this man became a hero at once in firmness and elevation; and this not by any artificial discipline of his imagination, but from a genuine and resistless enthusiasm in his own moral delineations. It then became a necessity of his nature to think and to write as if he himself had been one of the mighty warriors or statesmen, to glorify whose names it was his chief delight; now a Roman, now a Switzer of the ancient time, and now some other illustrious personage, whose character he superinduced upon his own in the moment of description. Moral and political grandeur had indeed for him so strong a charm, that he frequently deceived himself in his estimate of their amount.

With such a character of mind, Mueller could never be a historian who wrote only for the intellect, and still less a historian who wrote only for the memory. All that he read of remarkable persons and events became, in his imagination, a series of animated pictures. He must represent and paint, and he painted with few strokes, and happily, as if from life; while truth, as far as this could be discovered by historical research, was of greater value in his eyes than all the ornaments of rhetoric. His imagination was only active to place what he read before him in a living form. His historical delineations were inspired with the warmth of his peculiar temperament, but not misrepresented. As he himself was animated by whatever was good, and generous, and great, so, too, he wished to animate his reader by a sympathy with his portraits, and through the instructions which history conveys. But in Mueller's view, history must be instructive in a degree of which few historians have any conception. His free and clear intellect, adhering to no philosophical system, and with little inclination towards the abstract sciences in general, but penetrating deeply into the internal connection of historical events, was able to extract from this connection political and moral principles, which, though manifest even to the unlearned reader, when placed before him, are overlooked even by the enlightened thinker, when his observation is not guided by the legitimate deduction of causes and effects. And in this historical deduction, if we except Thucydides and Tacitus, Mueller has no superior. Not that he is equal to these great originals, or even to some modern historians, in the detailed developement of events, and in the arrangement of circumstances in the order of their absolute and relative importance. For the adequate attainment of this great end Mueller was disqualified by a certain deficiency in the powers of abstraction and combination. The ideas, in his representation, display no regular subordination; they are frequently crowded together, transposed, or dragged

Mueller.

behind. In this respect he is more peculiarly opposed to Tacitus, although the Germans have fondly styled him the twin brother of that great historian, who, in the distinction of what is principal and accessory, has no equal, and almost no likeness, among the historians either of ancient or modern times. Thucydides and Tacitus he more nearly resembles in the energy and laconic brevity of his style. Pleased only with a strength and fulness of thought, he abhors all that is empty, trivial, or redundant. Impelled by youthful enthusiasm to write the history of his native Switzerland, and dwelling, as it were, for years among the original documents from which his materials were compiled, his powerful style insensibly contracted a certain antique colouring from the language of the ancient chronicles; and thus it is that his diction more vividly expresses the character of that peculiar period, which, during the interval of composition, was then living in his own imagination. What was tasteless and offensive in the style of the old chronicles was indeed softened down in Mueller's cultivated mind; but while his intellect was engrossed with the connection of events, a laconic brevity had for his individual taste an irresistible charm, even when purchased at the expence of easy and natural expression. Mueller's *History of the Helvetic Confederacy*, the work on which he laboured longest, and to which he applied the whole force of his industry and talents, is the book in which we may best discover the spirit of his historical composition, in all its qualities both of comprehension and detail. But this work, one of the most singular products of great historical intellect, requires so close an attention to a multitude of small matters of fact, the details of which might easily have been omitted, and from the continued brevity, combined with the antiquated costume of the expression, exacts from the reader, unaccustomed to such a style, so vehement a stretch of thought, that we are ever and anon compelled to lay aside the book and breathe, in order to collect new strength for the perusal. Indeed, no book has, perhaps, been so much praised, and so little read, as the *Helvetic History* of our author. Mueller, who, from youth till death, and amid literary and political occupations of another kind, always considered the history of his native country as the principal object of his life, had so accustomed himself to that character of composition, which he thought accommodated to a history of Switzerland, that in his other writings, he is not wholly able to divest himself of its peculiarities. His *Universal History*, first drawn up in French, for a society of young persons who were his pupils at Geneva, afterwards with greater care re-written in the German tongue, and first published after the author's death, though comprising, in abridgment, all ancient and modern ages, is, however, far inferior in historical value to the history of Switzerland; but the nature of its subject is more agreeable to the majority of readers; and in the condensation of the matter, the style has a certain facility, in which we easily recognise the man to whom French was in his youth a second mother-tongue.

Of the other writings of Mueller, the most remarkable are the *Letters*, which were not written

Mueller
||
Mutis.

for the world, but published after his death in the collection of his works, of which they occupy several volumes. From these letters we learn the character of the man on its fairest and most honourable side; and we likewise see how far his style is removed from the affectation with which he has so often been reproached. For in these letters, written rapidly, without premeditation, and to confidential friends, the historian of the *Helvetic Confederacy* is recognized in every sentence; and the absence of a smooth and polished diction is in itself an excellence, when contrasted with the paint of letters written for admiration and display.

MUTIS (JOSEPH CELESTINO), an eminent Natural Historian, but peculiarly distinguished for the ardour of his botanical researches; was a native of Spain, born at Cadiz, 6th April 1732. His parents were respectable inhabitants of that city, and conferred on him the best elementary education that could be acquired in Andalusia. His first instructions were received in the College of San Fernando, in his native city, from whence he removed to the University of Seville. In both these seminaries he was distinguished, as well by his application and talents, as by the modesty of his demeanour. He attended the classical and mathematical course as taught in the latter seminary, as well as to the study of theology; and during his residence there, sedulously applied himself to anatomy, medicine, and natural history. The ardour he displayed for this class of pursuits was great, so that, when he removed to Madrid in 1757, he had made such progress as to enable him to become a lecturer on anatomy. It was then usual for the Court of Madrid to select some promising young men, and send them to Leyden, Paris, or Bologna, to improve their faculties, and advance their knowledge of the sciences. Mutis was selected for this purpose, but about the same period Don Pedro Messia de la Cerda was appointed Viceroy of New Granada, and proposed to the ardent naturalist to accompany him, in the quality of physician, to that interesting country. His natural modesty and love of retirement induced him to relinquish the opportunity of visiting different countries, and thereby increasing his knowledge in Europe, and to devote himself to the examination and description of those objects of natural history which the mountains of South America presented, and which had previously been scarcely explored by any scientific European.

He embarked with the Viceroy, and landed at Carthagena in the year 1760. The various new productions that met his eye at every point in that hot climate, did not detain him from ascending towards the mountain plain, where at the city of Santa Fé de Bogota he fixed his abode.

Mutis.

He had scarcely reached the destined place of his residence, before he began to arrange his plan for the collection of those plants to whose study he was attached, and of which the descriptions formed the delight of his life, and the basis of his future fame. He soon began a correspondence with Linnæus, which continued during the life of that celebrated man, who procured his admission to the academy at Stockholm. His accuracy, diligence, and enthusiasm, were highly estimated by the Swedish botanist, who felt, in the eulogiums he paid him, that he very imperfectly gratified his own sentiments of respect and admiration. * His skill was speedily known through Europe by all the botanists of considerable eminence, as his discoveries were communicated to many of them, through the extensive correspondence which he maintained. †

At the time Mutis arrived at Santa Fé de Bogota, that capital was in profound ignorance of science, and, even in the university, the true system of the universe was so little known, that he is represented as having encountered great difficulties, when he first taught that the world turned on its own axis, revolved round the sun, and was in reality only a planet of the solar system. With the approbation of the Viceroy, he began to dispense mathematical, and especially astronomical knowledge, to the pupils in the college of the Rosario; and he had the satisfaction, long before the close of a protracted life, to see a race of scholars formed on the principles of the Newtonian philosophy, in spite of the anxious and alarming fears of their parents, who, on its first introduction, considered it impious, or at least heretical.

He continued diligently exploring the Andes for every vegetable production, during the intervals of instruction in astronomy, and continued both pursuits with unabated ardour. When his patron Cerda had finished the period of his Viceroyship, he proposed to Mutis to return with him to Spain, but he was so much fascinated with the solitude of the vast woods and extended plains, with the features of nature displayed on the boldest scale, and the deep azure of the unclouded sky, that he determined, under their favouring auspices, to spend the rest of his life in South America, in the contemplation of vegetation, and of the starry world. His studies, instead of producing scepticism, strengthened his religious faith, and, under its influence, he entered into holy orders in 1772. From that period, he divided his time between religion and the sciences, and, whilst in the former he was a model of ecclesiastical virtue, he displayed in the latter the qualities of a genuine philosopher.

It was a fortunate circumstance, both for the science of botany, and for the fame of Mutis, that the Court of Madrid felt a peculiar interest in the promotion of that study, and appointed commission-

* In memoriam Josephi Cælestini Mutis, Americæ summi Botanici, qui historiam plantarum Americæ, in primis Palmarum, pulcherrimam parat, et plurima nova hinc opuscula communicavit. *Lin. Suppl.* p. 57. Nomen immortale quod nulla ætas unquam delebit. *Linn.*

† Cavanilles, in writing, thus expresses himself: "In honorem sapientissimi viri (J. C. Mutis) qui jure merito Botanicorum in America princeps salutatur, debetque etiam inter primates Europeos collocari."

Mutis.

ers in each of its extensive dominions in America to investigate, arrange, describe, and draw their various productions. Mutis was appointed president of the Botanical Board for the Viceroyalty of Santa Fé, and commenced his operations by the project of that great work the *Flora of Bogota*, which only the munificence of a government could enable him to undertake. In 1782, he selected the spot most favourable for executing this great design, and, judging the central situation of Mariquita, at the foot of the mountains of Quindiu, to be the best adapted for his purpose, he removed thither, and resided in that place for the succeeding seven years, in pursuance of his plan of study. The place was admirably chosen; for though at the foot of the Andes, it is on a high level, and in a temperate climate; and, being in the vicinity of the river Magdalena, though considerably higher, it has the advantage of easy access to every degree of temperature, and to all the various family of plants which the greatest possible differences of climate can produce. In this secluded town, he and his pupils were constantly employed in roaming in the extensive plains, penetrating the thickest woods, scaling the highest mountains, and at times encountering the severe heat of the valleys, whilst collecting every rarity of the vegetable kingdom. He there created a class of painters, who drew the plants as they were collected: he had a school of engraving, in which were executed some of those large plates, which have excited so much admiration among the botanists and artists of Europe. The state of his health, arising principally from the exertions he made, and the hardships he encountered in these pursuits, induced him to remove from Mariquita in 1772, and fix his residence again in the capital, to which he was also drawn by the desire of being nearer to a greater number of artists, than could be collected in the retired spot from whence his exploratory journeys had been directed. His labours in perfecting the *Flora* were continued with unabated industry till the end of his life, and after his decease the work was continued by some of his pupils; though it has received serious interruptions from the civil wars, in the course of which some of those appointed to continue it were cut off amidst the contests of the various revolutionary factions. Among these is particularly to be regretted Don Francisco Caldas, who was endeared to Mutis, and most nearly resembled him in his industry, and his attachment to the study of natural history. Besides the great work, the *Flora*, Mutis finished one on the history of the trees of the quina species, and exercised his great acuteness in the investigation of the varieties of that family, whose bark has introduced a new era in the practice of medicine.

Amidst his botanical labours, Mutis never neglected his astronomical observations and experiments. It had often been suggested by philosophers in Europe, that the moon had probably an influence on the barometer, similar to what exercises on the tides. The situation of Santa Fé was favourable for a variety of experiments, which Mutis conducted, and by which he ascertained the fact so clearly, as to remove all doubts on the subject. He was instrumen-

Mutis.

tal in obtaining powers from Madrid for the construction of an observatory on the summit of the Andes, at a far higher elevation than any of the observatories of Europe are placed. He had remarked, that the blue of the firmament appears darker in proportion to the elevation at which the observer stands, and that on the highest attainable situations, the sky seems almost black; so that the stars shine with a brilliancy uninterrupted by clouds, and even in day-light, are visible without the help of glasses.

He deemed the position favourable for astronomical observations, and especially for those of the fixed stars; for being near the equator, it commanded a view of the constellations both of the northern and southern hemispheres; and from its height, the observer is little liable to interruption from intervening clouds, or to errors from the inconstancy of the refractions. At his earnest recommendation, and under his inspection, the observatory was begun in 1802, and finished in 1803. Some instruments were collected in the country, and others were ordered from Europe. The first were, as may be supposed, destitute of those improvements which have been more recently introduced; and it unfortunately happened, that some of those exported from Europe were lost on the passage. The apparatus had not been completed when Mutis died, and the political storms which have agitated that country have prevented the completion of the collection. The founder had, however, directed the course of observations to be prosecuted with as much attention as the imperfection of the instruments would admit. Though the wise intentions of Mutis have been delayed; we may hope they have not been frustrated, but may look forward to a time when the catalogue of fixed stars in the southern hemisphere shall be considerably augmented, and their positions determined with the greatest accuracy. In the mean time, some astronomical and meteorological observations have been made and published, in a periodical register, and the exact latitude and longitude of the observatory has been determined. Its elevation above the level of the ocean, as determined by barometrical observations, frequently repeated, is 9416 feet. As this observatory is the first erected in South America, as it stands much higher than any other that ever was constructed, if its advantages shall be properly improved, it will be a benefit to science, and a durable monument to the fame of its founder.

Mutis enjoyed good health through a long life, which was closed in a manner worthy of a philosopher and a Christian, without pain or struggle, 11th September 1808. He left various manuscript works on plants, on meteorology, and on mining; an herbary of upwards of 20,000 plants, more than 5000 drawings of plants, and a large collection of woods, of shells, of minerals, and skins of animals. He had also a very extensive collection of oil-paintings, of all the various animals of the viceroyalty coloured, in exact conformity to nature. It was the last wish he expressed, that his valuable collections might furnish the basis of a national museum; but the turbulent season which commenced soon after his death,

Mutla
" "
Mysore.

and the unsettled state in which public affairs have since continued, have hitherto prevented the fulfilment of his wishes. See *El Espanol. Diario de Santa Fe.* (w. w.)

MYSORE, properly **MAISOOR**, a large province of the south of India, principally situated between the 11th and 15th degrees of northern latitude, and now surrounded by the British territories, subject to the presidency of Madras. This province consists of a high table land, elevated 3000 feet above the level of the sea, from which rise a number of lofty hills, containing the sources of many rivers, the principal of which are the Caverry, Toombuddra, Vedawati, Bhadri, Penar, &c. The climate of this elevated region is temperate and healthy to a degree unknown in any other track of similar extent within the tropics. The rainy season is here more moderate than on either of the sea coasts, but of much longer duration; and during other seasons of the year the verdure is frequently refreshed by enlivening showers. Its soil produces not only all the grains and vegetables of other parts of India, but also many of the fruits of Europe. The cultivation is also much aided by means of reservoirs and wells, from whence the farmers irrigate their fields and gardens. The inhabitants are in general Hindoos; but the country having been so often the scene of warfare, it is not nearly so populous as Bengal, and some other of the British provinces. It produces horses, cattle, sheep, and swine, but none of them of a good size. This province is divided into three districts, named Fata-na, Nagara, and Chatrakal: each district is managed by an Amildar, who is an officer of justice, police, and revenue, and who is accountable for his conduct to the ministers of the Rajah, who are kept to their duty by the presence of the British resident.

As this province is now particularly connected with the British interests, and, from a rival state, is become one of our staunchest allies, it is requisite to enter at some length into its political history. The ancestor of the reigning family is said to have been the chief of a band of herdsmen, who emigrated with their flocks and cattle from the province of Gujerat, and were allowed to settle in Mysore. The first person of this tribe who distinguished himself was named Vijeya, in consequence of an act of bravery. He married the heiress of the *Wadiar*, or chief of the town of Caroogully and its dependencies, and succeeded his father-in-law. His immediate successors are not known; but, in the year 1507, Cham Raj took possession of the government, but still acknowledging himself as a subject of the Maha Rajah of Annagoondy, who was a descendant of the ancient Hindoo monarchs of Bijanagur. Tim Raj succeeded in 1548, and annexed some other districts to his government. Heere Cham Raj ruled from 1571 to 1576, and was succeeded by his cousin Raj Wadeyar, who appears to have taken advantage of the declining power of his lord paramount, not only to annex to his own estates those of the Rajah of Chickraipatam, but to take possession of the city and fortress of Seringapatam. This event occurred in the year 1610, and may be considered as the æra of their sovereignty. After this event, he subdued several of the neighbouring Wadeyars, and kept them in con-

finement at Seringapatam. He died in the year 1617, and was succeeded by his grandson Cham Raj, who added considerably to the Mysore territories, and died in 1637. He was succeeded by a posthumous son of the former Rajah, named Immadee Raj, who, in the course of a short time, was poisoned by his prime minister. Cauty Revy Narsa Raj, second cousin of the deceased, was the next sovereign of Mysore. He made various conquests, and reigned till 1659. He was the first prince who established a mint, and coined the *fanams* and *pagodas*, still current, which go by his name. Dud Deo Raj was his successor; he made several conquests, and died in 1672. Chick Deo Raj mounted the throne in 1672, and died in 1704. This prince completed the subjugation of the turbulent landholders, made a number of prudent regulations which still exist; and, among other accessions, acquired by purchase the town and fortress of Bangalore. He also sent an embassy to the Mogul Emperor Aurungezebe, who conferred on him a splendid title, and granted him permission to sit on an ivory throne, which is still in existence, and was used on the late installation. Cauty Raj, son of the last sovereign, mounted the throne in 1704. Having been born deaf and dumb, he was called the *Dumb Rajah*. It was in this reign that the great influence of the Dulwoy, or prime minister, commenced, which ever after rendered the Rajah a mere pageant. After a nominal reign of ten years, the Dumb Rajah died, and was succeeded by Dud Kishen Raj, who left the management of affairs entirely to his ministers, and died, after an inglorious reign, in the year 1731. He was succeeded by Cham Raj, who, not having been found of a sufficiently pliable disposition, was deposed and imprisoned by his ministers, in the year 1734. On this event, the Mysore ministers deviated from the regular line of succession, and chose a boy of five years old, of another branch of the royal family, named Chick Kishen Raj, to be the pageant of their government. The division of public business was at that period distributed in the offices of, 1st, Dulwoy, or commander-in-chief; 2dly, Serv Adikar, or comptroller of the revenue; and, 3dly, Purdhan, or privy counsellor. The first of these offices was held by Deo Raj, the second by Nunjeraje; but they subsequently exchanged appointments, and the influence of the latter was much increased by the marriage of his daughter to the young Rajah, in the year 1746. It was under the command of Nunjeraje Dulwoy, that a large Mysorean army marched to the assistance of the British, and their ally the Nabob Mohammed Aly, in the year 1753; but as the promised bribe, held out for his assistance (the cession of the fortress of Trichinopoly), was not complied with, he shortly after became their enemy, and for nearly two years laid siege to Trichinopoly; but, in the end, was compelled to abandon it, in consequence of the invasion of Mysore by an army of Mahrattas. From this period may be dated the decline of the minister's power, the downfall of the Hindoo dynasty, and the succession of a Mahometan usurper, whose history being not generally known, it is deemed requisite to insert an abridgment of it here.

The great-grandfather and grandfather of Hyder

Mysore. Aly were both named Mohammed, were religious persons, who emigrated from the Punjab and settled in the vicinity of the tomb of Geeso Deráz, the famous saint of Kalberga. The son of the younger Mohammed was named Futteh Aly, who, having entered the army as a private soldier, rose by degrees to the rank of commander of a regiment, with the title of Naick. This person improved his fortune by marriage, but was killed in an engagement about the year 1729. Some time previous to his death, he had raised a mausoleum over his father and his wife, in the vicinity of the town of Colar, and was buried there. After the battle in which Futteh Aly was killed, his family were taken prisoners, and plundered of every thing they possessed. The widow, accompanied by her two sons, Shabaz-Sahib and Hyder, boys, took refuge with her brother Ibrahim, who commanded a small body of *peons* or infantry, in the service of the governor of Bangalore. When the elder brother Shabaz had attained a sufficient age, his uncle procured for him a recommendation to an officer of rank in Seringapatam; and he was received into the service as a subordinate officer of infantry, in which situation he distinguished himself, and gradually rose to the command of 200 cavalry and 1000 infantry. It is probable, that Hyder profited by the good fortune of his brother, and was employed by him in a subordinate situation; but he does not appear to have distinguished himself till the year 1749, when, during the siege of Deonhally, by his intrepidity and valour, he attracted the attention of the Dulwoy Nunjeraje; and, upon the capitulation of the place, was promoted to the command of it, with a garrison of 200 infantry and 50 cavalry. Permission was also granted him to augment the number of troops, if he found a suitable site. During the contest between the Nizam Nurr Jung, and his rival Muzuffir Jung, in the year 1750, Hyder Aly commanded part of the quota of Mysore troops, and distinguished himself in resisting the French column; but as soon as Nasir Jung was killed, he employed his followers in plundering the camp of his late master; and, amongst a number of other valuables, carried off two camels laden with gold, 300 horses, and 500 stand of arms, all of which he conveyed safely to Deonhally.

Hyder Aly was again employed at the siege of Trichinopoly; and during the battle of the 17th of August 1754, between the British and the French armies, with their allies on both sides, Hyder seeing the baggage of the British left without protection, ordered some of his troops to amuse the Tanjorine cavalry in front, whilst he with another body galloped round, and fell upon the rear of the convoy, amongst which he created great confusion, and seized 35 carts laden with ammunition and stores. On the retreat of the Mysoreans in 1755, Hyder was detached in the command of an army, consisting of 5000 infantry, 2500 cavalry, six guns, and a number of irregular troops, to secure the district of Dindigul. During the three years he continued in the government of Dindigul, he very considerably increased the number of his troops, disciplined his battalions, and took into his service several French artificers, under whose superintendence he formed a laboratory, arsenal, &c.

Mysore. In the year 1758, a serious mutiny having broken out amongst the troops at Seringapatam, Hyder Aly was ordered to march thither with all his regular corps. Partly by fair means, and partly by force, he succeeded in quelling the mutiny, and in disbanding the army; in reward for which service, he was gratified with the fortress and adjoining district of Bangalore, as a fief or personal estate. In the following year, Hyder was invested with the command of all the troops employed against the Mahrattas, and was at the same time authorized to conclude a peace with them; but as this object could not be obtained without a large sum of money, and the government could not advance above half the amount, he was directed to borrow the remainder from the bankers; and in order to effect this, certain districts were assigned to him, to be held in pledge till the bankers should be reimbursed. Having appointed his own collectors to the districts, he borrowed the money, satisfied the Mahrattas, and returned in triumph to Seringapatam. His reception by the Dulwoy and young rajah was most gracious; by the former he was distinguished by the epithet of son, and by the latter honoured with the title of *Behaudee* (the champion), which he ever after retained. In this sketch of the history of Hyder Aly, it is impossible to describe the various intrigues by which he subverted the authority of the Dulwoy (minister), and got the rajah completely into his own power. But his overweening confidence had nearly ruined him. In the month of May 1760, Hyder Aly was induced, by the intrigues of the French, to detach to their assistance almost the whole of the regular army then at Seringapatam; whilst he continued to reside in a garden a short distance from the city, with a guard of only 100 horse, and a battalion of infantry. The rajah and his mother, a woman of considerable talent, weary of the tyranny of their oppressor, entered into a secret treaty with a Mahratta chief, who was encamped on the frontiers, and who agreed to send, on an appointed day, 6000 chosen horse to their assistance; but owing to the procrastination of the Mahrattas, and an ill-timed attack from the foot on the cantonment of Hyder, he effected his escape with his hundred cavalry, attended by some camels laden with treasure, and succeeded in reaching the fortress of Bangalore, which was garrisoned by his own troops. This event took place on the 13th of August 1760. Immediately on Hyder's entering Bangalore, he sent off an express to recal the army from the Carnatic, under the command of his brother-in-law Mukhdum Sahib; and dispatched orders to the various detachments of his troops, dispersed over the country, to join him without loss of time. By degrees he was joined by his detachments, by new levies, by the Carnatic army, and by what was of great consequence, 200 French European cavalry, and 100 infantry, with some light artillery. With these forces, aided by intrigue, he defeated the Mysore troops in several engagements, and in the month of May 1761, again got possession of the person of the rajah. Hyder Aly, although now possessing all the real power of a sovereign, was still desirous of legalising his usurpation; he

Mysore.

therefore, by means of presents or concessions, received from the Nizam of the Dekhan a grant of the zemindary of Mysore, with a patent constituting him a *Hefi Hazary*, commander of 7000 horse in the imperial service, and the title of Nabob Hyder Aly Khan Behauder.

In the year 1763, he conquered the countries of Bednoor, Soonda, and Canara; and in the three succeeding years, Calicut, and the greater part of Malabar. In 1766, the rajah Chick Kishen Deo died. When this circumstance was reported to Hyder, who was then at Coimbatore, he ordered the funeral rites to be performed with all the usual ceremonies, and directed that the eldest son of the deceased, named Nunje Raj, should be placed on the throne, with the same parade and pomp as had formerly been used for his ancestors. Nunje Raj died, or was murdered, after a nominal reign of five years, and was succeeded by his younger brother Cham or Syama Raj, who, by the indulgence or policy of Hyder, was installed in the same manner as his predecessor.

In 1767, the Mahrattas and the Nizam, aided by a British auxiliary force, entered into an alliance against Hyder Aly. They in consequence invaded Mysore, and after having taken several of the fortresses, advanced towards Seringapatam. In this dilemma, Hyder ordered all the forage to be destroyed, and took post on the banks of the river Cavery, in an entrenched camp. After some days skirmishing, Hyder contrived, by his wonderful skill in politics, not only to make peace with the Mahrattas, but to conclude an alliance with the Nizam against the British. In virtue of this treaty, the allied forces invaded the Carnatic in September; and on the 26th of that month a general engagement took place in the vicinity of Erroar. The British gained the victory, by which the Nizam, being intimidated, was glad to make peace, leaving his ally to extricate himself in the best manner he could. Hyder, much mortified by this event, commenced a regular retreat to his own country, and was pursued by the British forces under General Smith. When both armies had advanced nearly to Seringapatam, Hyder leaving his infantry and artillery to continue the retreat, wheeled off with all his cavalry, turned the rear of the British army, re-entered the Carnatic, and in a few days was at the walls of Madras. By this manœuvre, he so intimidated the Madras government, that they were glad to make peace with him. The terms of the treaty were short and simple. All prisoners and places taken during the war were to be restored, freedom of trade was stipulated, and an offensive and defensive league concluded.

In the year 1771, Mysore was invaded by a powerful army of Mahrattas, who, after defeating Hyder, advanced to, and blockaded his capital; but fortune again favoured him, by the indisposition and death of the young Peishwa, by which event dissension was sown amongst the Mahratta chiefs, and enabled Hyder to bribe them to retreat. The years 1773, 1774, 1775, and 1776, were devoted to the disciplining of his army, and to the gradual extension of his territories to the north and west. This he was en-

abled to do by the dissensions of the Mahratta chiefs and the Nizam's forces.

In 1777, Cham, or Syama, the young Mysore Rajah, died without issue. Upon this occasion, Hyder ordered eight or ten boys, lineally related to the royal family, to be brought before him, and made choice of one of them, nearly in the same manner that Ulysses discovered Achilles. This boy, whose name was also Cham or Syama Raj, was the father of the present Rajah.

By the treaty made with Hyder in 1769, the British had agreed to assist him against all his enemies; but when called upon to act against the Mahrattas in 1771, they had declined, and from that period Hyder harboured the most bitter hatred against them. The year 1779, when the British had quarrelled with the Mahrattas, and given offence to the Nizam, seemed a favourable opportunity of satiating his revenge; he therefore, by means of his emissaries, concluded an alliance with the above mentioned powers, and invited every other sovereign in Hindostan to join the confederacy, and to make a simultaneous attack on the British territories in their respective vicinities. In conformity with this plan, Hyder Aly entered the Carnatic in the month of July 1780, at the head of an army consisting of 30,000 cavalry, and 40,000 infantry, with a numerous train of artillery, aided by a corps of Europeans, and a number of French officers. Hyder commanded in person the centre or main body. The left wing was under the orders of his son Tippoo Sahib, and was destined to attack the northern Circars; while the right wing, under one of his most esteemed generals, penetrated into Madras and the southern districts. During Hyder's former invasion of the Carnatic, in 1767, he had caused his army to refrain from atrocities, and to treat the prisoners with gentleness; but on this occasion he boasted, "that he was the engine of God's wrath, for the punishment of the people of the Carnatic." His army was, therefore, guilty of the greatest cruelties, laying waste the whole of the country with fire and sword; not only the military who were taken prisoners, but the peaceable inhabitants of the villages, were driven off like flocks of sheep to Mysore. The boys were made Mahometans, and the girls disposed of as slaves.

Notwithstanding Hyder was frequently defeated by the British forces under Sir Eyre Coote, his numerous cavalry and well equipped artillery enabled him to overrun the country at pleasure, and left no part of it in the possession of his enemies, except Madras, and some other fortresses. This system of warfare continued till the death of Hyder, which took place in the city of Arcot, on the morning of the 7th December 1782, at the age of 64 years. At the period of Hyder's decease, his dominions, exclusive of his conquests in the Carnatic, comprehended nearly 80,000 square miles; his territorial revenue amounted to two millions sterling. Although his army consisted of 150,000 men, his treasure contained several millions in bullion and specie.

Tippoo Sultan, the eldest son of Hyder, having joined the army on the 2d January 1783, quietly

Mysore.

Mysore.

succeeded to the empire of his father. A feeble attempt had been made in favour of the second son, called Abd al Kereem, now a state prisoner in Calcutta, but was considered of so little consequence, that the tyrant never attempted the life of his brother, who either was, or pretended to be deranged, and always wore the dress of a *fakier*, or hermit.

The invasion of the western or Malabar coast by the British, and the capture of Bedenoor, compelled Tippoo to relinquish the views of his father on the Carnatic, and to proceed with all expedition to the defence of his own territory. He left Arcot early in March; and having, in the course of the month of April, reached Bedenoor, he compelled General Matthews to capitulate. The principal articles of the capitulation were, that the garrison were to pile their arms on the glacis, but to retain all their private property; they were then to be marched, by the shortest route, to the sea side, and thence to be embarked for Bombay. But Tippoo, under pretence that the public treasure had been made away with, caused all the prisoners to be plundered. They were afterwards fettered, and then dispatched to different fortresses, where most of them died through hard treatment; the general and several of the principal officers were beheaded.

After this event Tippoo marched to the seaport of Mangalore, but was baffled in the siege of that place, till, in consequence of the peace between England and France, the French auxiliaries having declined further co-operation with him, and the recent successes of the British in other parts of the country, compelled him to make peace. On the 11th of March 1784, a treaty was concluded between Tippoo and the British, the principal articles of which were, that the places taken by either party during the war were to be restored, and that all the prisoners on both sides were to be released.

Tippoo being now at liberty, employed the remainder of 1784 in the complete subjugation of the Nair of Malabar, and the conquest of the Coorg country. Having thus vanquished or made peace with his enemies, he returned in triumph to Seringapatam; when, feeling himself perfectly established, and his authority acknowledged, both by his subjects and the neighbouring powers, he ostentatiously mounted the throne, and assumed the title of Sultan, thereby throwing off all allegiance to or dependence on the Rajah of Mysore or the Emperor of Hindostan; for although the name Sultan may have been given him at his birth, it certainly was never used as a title during his father's lifetime.

During the years 1785, 1786, and 1787, Tippoo was engaged in hostilities against the Mahrattas and the Nizam, in which victories were gained and defeats sustained by both parties; but the general result was in favour of the Sultan. The year 1788 was occupied by Tippoo in reforming the province of Malabar, and the forcible conversion of the inha-

Mysore.

bitants to the Mahometan religion. In the following year he invaded the territories of the Rajah Travancore, who being one of the British allies, applied to them for assistance, which circumstance brought on the subsequent war, at the conclusion of which, in March 1792, Earl Cornwallis, at the head of the allied forces, compelled Tippoo Sultan to pay the sum of four millions of money, and to relinquish the half of his dominions.

In the year 1796, the Mysore Rajah Cham Raj died, leaving an only son, then two or three years old, to inherit the dignity of his ancestors; but the haughty Sultan would not condescend to acknowledge even a nominal superior; and so far from exalting the boy to the throne of his forefathers, he barely allowed him to exist, in squalid poverty and humiliating contempt. From this period till the year 1799, Tippoo was engaged in constant intrigues with the French, and all the powers of Hindostan, in order to raise a confederacy against the British nation. His correspondence was detected by the Governor-general, Lord Mornington, now Marquis Wellesley. War was determined on; the British forces, with their allies, under the command of General Harris, marched to Seringapatam, and on the 4th of May 1799 put an end to the empire and life of Tippoo Sultan.

It would have been no less unjust than impolitic for the British either to have taken possession of the whole of the conquered territory for themselves, or to have restored the family of Tippoo to power. It was therefore determined to place on the throne Krishna Odiaver, the son of the last Rajah, a boy of five years old; to place him in possession of the ancient capital of Mysore with a territory surrounding it equal to that possessed by any of his ancestors, and yielding a revenue of L. 1,030,000 sterling, with the entire management of the country by his own officers; but subject to the general superintendence of a British resident.

On the 30th day of June 1799 the ceremony of installing the young Rajah took place, in a temporary building erected for the purpose in the old fortress of Mysore. It was attended by the British Commander-in-chief, by many of the principal officers of the allied forces, and by an innumerable multitude of Hindoos, who testified their most unfeigned delight on beholding a person of their own religion, the orphan of a much injured family, restored to the possessions of his ancestors. Previous to the installation pensions had been granted to most of Tippoo's officers, and the family of the Sultan were sent as state prisoners to Vellore, whence they were subsequently removed to Calcutta, where they now reside upon liberal allowances, and enjoy a degree of freedom much greater than would have been their lot, had these events not taken place.—(*Edinburgh Gazetteer, or Geographical Dictionary, Vol. IV. Part II.*)

ADDENDUM

TO

VOLUME FIFTH.

MOLLUSCA.*

Mollusca.

THE primary division of animals into VERTEBRAL and INVERTEBRAL, indicated in the writings of the ancients, by the terms sanguineous and exanguineous, possesses many advantages, and now appears to be universally adopted by zoologists. Among the vertebral animals, the brain is collected into one mass at the anterior extremity of the body, and sends out a nervous cord, termed the spinal marrow, to the posterior extremity. These nervous portions are protected by a cranium and vertebral column.

The invertebral animals occupy a lower station than those belonging to the vertebral group. Their nervous system, in particular, is less fully developed, and their organs of perception are greatly reduced in number. They may be distinguished readily by the following negative character :

INVERTEBRATA.

Invertebral Animals.

ANIMALS DESTITUTE OF A SKULL AND VERTEBRAL COLUMN FOR THE PROTECTION OF THE BRAIN AND SPINAL MARROW.

The invertebral animals have few characters of a positive kind, which they possess in common. The skin, in general, consists only of a corium and cuticle, both of which, according to circumstances, are furnished with appendices, in the form of shells, crusts, scales, or hairs. These, in general, supply the place of the osseous system, serving as a protec-

tion to the viscera, and as supports to the muscles. The blood, in those cases where a circulating fluid can be detected, is usually of a white or grey colour, seldom inclining to red. When there are both systemic and pulmonic ventricles, they are not united as in the vertebral animals. With the exception of the genuine viviparous mode of reproduction, the invertebral animals exhibit all the other modifications of that function.

In attempting the division of invertebral animals into subordinate groups, the condition of the nervous system furnishes characters of importance. In one extensive class, which, from their starry form, have been termed *RADIATA*, the nervous matter appears to be disseminated among the different organs, and never appears in the form of a brain, with its connected filaments. In another class, equally extensive, and which, with propriety, may be denominated *GANGLIATA*, the brain appears in the form of a collar, surrounding the gullet, near its entrance into the stomach, and sending out filaments, which, in their course, expand into ganglia. In this last group are included the classes *Annulosa* and *Mollusca*. The classification of the *Annulose* animals has been already communicated to our readers. The *Molluscos* tribes now claim our attention. The essential characters, by which these two classes may be distinguished, depend on the condition of the nervous filaments proceeding from the brain ; the principal of which, in the former, constitute a knotted cord proceeding to the extremity, while, in the latter, they separate irregularly.

Mollusca.

* See the word *MOLLUSCA*, p. 490 of this Volume.

Mollusca.

Independent of this internal character, molluscos animals are distinguished from those of the annulose division by the absence of articulated feet, or the cuticular processes which supply their place, and by the body not being divided into joints or rings.

Under the article CONCHOLOGY, a variety of details were given regarding the shells of molluscos animals, the characters furnished by these appendices of the skin which have been employed in their classification, the relative value of the different popular systems which have been proposed, together with some remarks on the physical distribution of the species, and the revolutions which, in former ages, they have experienced. The present article may, therefore, be regarded as a continuation of the one dedicated to Conchology, and as having more immediately in view the exposition of those characters which are now employed in the most approved systems of zoology.

Molluscos animals divide themselves into two great divisions, which are distinguished from each other by well defined characters. In the first the presence of a head may be recognised, together with eyes and even ears, in some of the groups. In the other, containing animals much less perfect in their organization, there is no head, nor vestiges of eyes or ears in any of the groups. The former have been termed *Mollusca cephalata*, the latter *Mollusca acephala*. This arrangement was first employed by the celebrated M. Cuvier, and afterwards by Lamarck and other modern systematical writers. In the last work of the former naturalist, this method is departed from, and six orders are now constituted of equal rank, instead of being placed subordinate to the two primary divisions, under which, notwithstanding, they can be suitably distributed.

I. DIVISION.

MOLLUSCA CEPHALATA.

Head distinct from the body, bearing the lips or jaws.

The head, or the anterior part of the body, on which zoologists have bestowed that denomination, possesses more or less freedom of motion, and, on the dorsal aspect, supports either tentacula or eyes, frequently both. The animals of this division exhibit so many modifications of form and structure, in all the series of organs, that the positive characters which they possess in common are few in number. They easily admit, therefore, of subdivision into inferior groups, which exhibit well marked characters of distinction. Two of these groups occupy a primary rank, and admit of the others being included under them as subordinate sections. In the first of these, the animals are all inhabitants of the water, and perform their progressive motion through that element by organs fitted for swimming. They are destitute of any ventral disc or which to crawl. In the second group, including animals which inhabit the land, as well as those which live in fresh water and in the sea, progressive motion is performed by means of crawling along the surface of objects, the body resting on a ventral disc, termed a foot.

I. Section.

NATANTIA.

ORGANS OF PROGRESSIVE MOTION FITTED FOR SWIMMING.

The organs of motion are situated near the anterior extremity of the body, and either consist of flexible tentacula, or membranaceous expansions. All the species reside in the sea. They are nearly of the same specific gravity with the surrounding fluid, in which they float about, having their motions in a great measure regulated by its changes. It is however probable, that, by means of some contractile movements, they are capable of varying their density, and of rising or sinking in the water. They swim slowly, even with their utmost efforts. M. Cuvier has distributed the animals of this subdivision into two classes, which he has termed Cephalopoda and Pteropoda.

I. Class.

CEPHALOPODA.

Fins in the form of tentacula, surrounding the mouth.

Cephalopodous animals consist of a body and head. The body is surrounded by a sac or tunic, closed posteriorly, and in part open anteriorly, for the orifices of the several organs. This tunic differs greatly in its texture, and is strengthened internally by testaceous or corneous productions, or externally by means of a spiral shell. The neck is more or less distinct from the sac. The head is flattened into a disc, in the centre of which is the mouth, and, towards the margin, the tentacula take their rise. The two Linnæan genera, Nautilus and Sepia, comprehend all the animals which are at present considered as belonging to this class.

I. Order.

NAUTILACEA.

Furnished with a multilocular shell.

This order is involved in the greatest obscurity. None of the recent species have been subjected to an accurate examination, so that their connection with the order sepiacea may still be considered doubtful. Enough is known of the animals of two of the genera, to furnish some hints for those who are fond of classifying animals from their analogies. These genera are *Spirula* and *Nautilus*.

In the *Spirula*, the shell, which is concealed under the skin of the back, is spiral, with the whorls separate, the mouth orbicular, the chambers perforated by a pipe, and the last cell produced into a tube. The position and use of this terminal tube are unknown. The *S. vulgaris* is the most common species, and inhabits the seas in the West Indies. In the restricted genus *Nautilus*, the shell is supposed to be external, and the body of the animal to be lodged in the last chamber, and to be fixed by a ligament which descends into the central pipe. In the shell itself, the turns of the spire are contiguous, and the last whorl embraces the others on the sides.

Mollusca.

Mollusca. The *N. pompilus* of Rumphius is the only species in which the animal has been detected.

The other genera which have been formed in this order depend exclusively on the characters furnished by the shells, and the resemblance which these bear to the preceding genera constitutes all their claim to be included in the present order. (See CONCHOLOGY, Genus 18, *Nautilus*.)

II. Order.

SEPIACEA.

Destitute of a multilocular shell.

The sac is strengthened by horny or testaceous plates, unless where the habits of the animal render such support unnecessary.

1. HEAD SURROUNDED WITH EIGHT ARMS AND TWO FEET.

The two feet are nearly similar in their structure to the arms, or tentacula, but considerably larger in their dimensions. They have their organ on the ventral side of the mouth, between that organ and the funnel. The suckers are pedunculated, with their margin strengthened by a corneous ring, furnished with teeth. The sac is furnished with fin-like expansions, and strengthened internally by corneous or testaceous ribs or plates. The head is divided from the sac on all sides by a neck. The margin of the anus is surrounded with tentacula.

Genus, *Sepia*.—The sac is furnished on each side throughout its whole length with a narrow fin.

The suckers are irregularly scattered on the arms and feet. The back is strengthened by a complicated calcareous plate, lodged in a peculiar cavity. This plate has been long known in the shop of the apothecary, under the name *Cuttle-fish bone*, and belongs to the species termed *S. officinalis*.

Genus, *Loligo*.—Calamary. Sides of the sac only furnished partially with fins.

The suckers are disposed on the arms and feet in a double row. The dorsal plate is flexible and corneous, imbedded in the substance of the sac, and is multiplied with years. The *Sepia loligo* of Lin. is the type of the genus.

Dr Leach has described three new species of the genus *Loligo*, which were collected by Mr Cranch during the voyage to the Congo, in the unfortunate expedition under the direction of Captain Tuckey. These species belong to a group which have the suckers produced into hooked processes. In two of these species, *L. leptura* and *Smithii*, the suckers on the arms, as well as the feet, are produced into hooks, while, in one species, *L. Banksii*, the feet only are armed with hooks.

The same distinguished naturalist has instituted a new genus nearly allied to *Loligo*, from two species collected during the same voyage. The following characters are assigned to it.

“Genus, *Cranchia*.—Body oval, sack-shaped;

Mollusca. fins approximating, their extremities free; neck with a frenum behind, connecting it with the sack, and with two other frena, connecting it with the sack before.

“Sp. 1. *Cranchia scabra*.—Sack rough, with hard rough tubercles.

“Sp. 2. *Cranchia maculata*.—Sack smooth, beautifully mottled with distant ovate spots.”*

HEAD SURROUNDED WITH EIGHT ARMS WITHOUT FEET.

The suckers have soft margins. The sac is destitute of fin-like expansions, and is either simple or strengthened in the interior by two short corneous processes. The head is united with the sac behind, without the intervention of a neck.

Arms all equal in Size.

Genus, *Octopus*.—Suckers arranged in a double row.

The suckers are sessile. The oviduct is double. The margin of the anus is simple. The *Sepia octopodia* of Lin. is the type of the genus.

Genus, *Eledona*.—Suckers on the arms disposed in a single row.

M. Lamarck has figured and described two species of this genus, in the *Mém. de la Soc. d'Hist. Nat.* One of these is a native of the Mediterranean, and is remarkable for giving out an odour like musk.

Arms Unequal.

Genus, *Ocythoe*.—Two of the arms at their inner extremities furnished with membranaceous expansions.

In this genus, which was instituted by M. Rafinesque, the suckers are in a double row, and supported on footstalks. In the specimens of the *Ocythoe Cranchii*, procured during the expedition to the Congo, Dr Leach observed “four oblong spots on the inside of the tube, resembling the surfaces for the secretion of mucus, two inferior and lateral, and two superior, larger, and meeting anteriorly. On the rim of the sac, immediately above the branchia, on each side, is a small, short, fleshy tubercle, which fits into an excavation on the opposite side of the sac.” *Phil. Trans.* 1817.

This animal was long considered as the fabricator of the shell termed *Argonauta* or *Paper Nautilus*. The observations, however, of Mr Cranch, the Zoologist to the Congo Expedition, have demonstrated that the shell is merely the temporary residence of this animal, which it quits at pleasure. “On the 13th of June,” says Dr Leach, “he placed two living specimens in a vessel of sea-water; the animals very soon protruded their arms, and swam on and below the surface, having all the actions of the common *Polypus* (octopus) of our seas; by means of their suckers, they adhered firmly to any substance with which they came in contact, and when sticking to the sides

* Narrative of an Expedition to Explore the River Zaire, usually called the Congo, in South Africa, in 1816, under the direction of Captain J. K. Tuckey, R. N. London, 1818, p. 410.

Mollusca. of the basin, the shell might easily be withdrawn from the animal. They had the power of completely withdrawing within the shell, and of leaving it entirely. One individual quitted its shell, and lived several hours swimming about, and showing no inclination to return into it; and others left the shells as he was taking them up in the net. They changed colour, like other animals of the Class Cephalopoda; when at rest the colour was pale flesh-coloured, more or less speckled with purplish; the under parts of the arms were bluish-grey; the suckers whitish." The specimens which furnished an opportunity for making the preceding observations were met with in the Gulf of Guinea, and afterwards on the voyage, swimming in a small argonauta, on the surface of the sea. The reader, who is desirous of farther information on this subject, may consult Dr Leach's *Observations on the Genus Ocythoe* of Rafinesque, and Sir E. Home on the *Distinguishing Characters between the Ova of the Sepia, and those of the Vermes Testacea that Live in Water*, in the *Philosophical Transactions* for 1817, Art. xxii. and xxiii. (both of which are added to the appendix of Captain Tuckey's *Narrative*), and a paper by Mr Say on the Genus *Ocythoe* in the *Phil. Trans.* 1819, Art. vii.

II. Class.

* PTEROPODA.

Fins formed of membranaceous expansions.

M. Cuvier, whose valuable papers on the Genera *Clio*, *Pneumodermon*, and *Hyalea*, include nearly all the accurate information which naturalists possess, divides the animals of this class into cephalous and acephalous. In the latter division he places the genus *Hyalea*. The head of the animal of this genus, with its inferior neck, may, however, be sufficiently recognized to remove all doubt of its existence.

The characters which may be employed in the classification of this group are numerous; but the influence which their different forms exercise on the habits of the species is still unknown. The following disposition of the genera, though it has no claims to a natural division, may be useful to the student in his investigations.

I. TUNIC STRENGTHENED BY A SHELL.

Genus, *Limacina*.—Posterior extremity of the body covered by a spiral shell.

The shell, which is very tender, makes one turn and a half, is flat on one side, with a large pillar cavity on the other. The fins are two in number, seated on each side of the neck. When the animal swims, the head with the fins are protruded.

This genus was instituted by Cuvier, for the reception of the *Clio helicina* of Captain Phipps, or *Argonauta arctica* of Fabricius. According to Mr Scoresby, it is found in great quantities near the coast of Spitzbergen.

Genus, *Hyalea*.—Posterior extremity of the body protected by two connected shelly valves.

The *Hyalea tridentata*, the best known species of the genus, was first noticed by Forskael, in his *Descriptiones Animalium*, p. 124, as an anomia, and inhabiting the Mediterranean. The same species was

likewise taken in abundance in the Gulf of Guinea, Mollus by the expedition under Captain Tuckey.

II. TUNIC DESTITUTE OF A SHELL.

A. Fins double.

Posterior Extremity with Leaf-like Ridges.

Genus, *Pneumodermon*.—Head with two bundles of tentacula.

The body is oval, with a narrow neck, and a fin on each side. The mouth is nearly terminal, furnished on each side with a fleshy lip, and beneath, with a fleshy chin. The tentacula consist each of a filament, with a tubercle at the end, pierced by a small hole, and considered as exercising the office of a sucker. M. Cuvier has figured and described the only known species, which he terms *Pneumodermon Peronii*, the trivial name being in honour of the discoverer, M. Peron.

Posterior Extremity Simple.

Genus, *Clio*.—Body ovate, with the tunic elongated and membranaceous.

The head is divided into two lobes, the summits of which are furnished with tentacula. The existence of eyes has not been ascertained. The *Clio Borealis*, a native of the Arctic Seas, is the type of the genus.

Genus, *Cleodora*.—Body covered with a triangular pyramidal tunic.

The fins are membranaceous. The mouth is situated between them, and is furnished with a semicircular lip. This genus was instituted by Peron, for the reception of the *Clio* of Brown. The *C. pyramidata* is the best ascertained species. Brown's *Jamaica*, p. 386, Tab. xliii. f. 1. Two other species were taken by the Congo expedition in S. Lat. 2° 14', and E. Long. 9° 55', and S. Lat. 2° 41' E. Long. 9° 16', "both having a spinous process on each side of their shell, near its opening. One species is beautifully sulcated transversely, and the other but slightly so." Tuckey's *Narrative*, p. 412.

B. Fin single.

Genus, *Cymbulia*.—Tunic cartilaginous and trough-shaped.

The fin is single, divided into three lobes, one of which is small, with two tubercles, and a minute fleshy beard. This genus was instituted by Peron, in *Annales du Museum*, T. XV. T. iii. f. 10, 11.

II. Section.

GASTEROPODA.

ORGANS OF PROGRESSIVE MOTION FITTED FOR CREEPING.

This is one of the most extensive groups of Molluscous animals. The marks by which it is distinguished are well defined, and the external and internal characters of the species have been successfully illustrated.

The Gasteropoda may be considered as having the body protected dorsally by the cloak, and ventrally by the foot. The cloak is either continuous, and usually more or less arched for the reception of the viscera underneath, or it is interrupted by a pro-

Mollusca. jecting bag, in which are contained the principal digestive and reproductive organs. This projecting bag is tapering and spiral, and always protected externally by a shell. When the cloak is continuous, the surface is variously marked, and frequently exhibits a particular portion, more elevated than the rest, in some cases concealing a testaceous plate, which has been termed the *shield*.

The *foot*, situate on the ventral surface, and in opposition to the cloak, exhibits a flat soft surface, consisting of interlaced muscular fibres. Its central surface serves as support to the viscera, while externally it constitutes the organ of progressive motion. It is a *sucker* rather than a foot, and enables the animal to adhere to objects when at rest, and to crawl from one place to another by a succession of adhesions, not unlike the leech. It is also used as a fin in swimming.

By the union of the cloak and foot, laterally and posteriorly, a sac is formed, which is open in front for the protrusion of the neck and head. The line of junction between the cloak and foot is marked, in general, by peculiarities in the condition of the margins of both.

The *neck* is usually divided from the cloak by a *collar*, or thickened margin belonging to the latter, or rather to the shield, while in other cases it is continuous. Underneath, the neck is frequently attached to the foot.

The *head* supports the tentacula and eyes, is free dorsally, but frequently intimately connected with the foot on its ventral side. The portion between the tentacula and the mouth is termed the *snout* (*le muse* of the French, and its margin *le chaparron*). The mouth exhibits various modifications of fleshy lips and corneous jaws. The inside of the cheeks are covered in some species with reflected teeth to aid deglutition. The *tongue* can scarcely be detected in some of the genera, while in others it is a simple tubercle, or a strap-shaped, spiral organ, armed with transverse rows of teeth. This spiral tongue, where it is fixed to the base of the mouth, is broadest, and there also the spinous processes are strongest. The spiral part is narrowest and softest, and folded up behind the pharynx. M. Cuvier conjectures, and apparently with plausibility, that the spiral portion comes forward into the mouth to act as a tongue, in proportion as the anterior part is worn by use and absorbed. (See his *Memoire sur la Vivipare d'eau douce*, p. 12.)

The organs of respiration exhibit the two modifications of lungs and gills, and enable us to divide the gasteropoda into two classes, which we have termed Pulmonifera and Branchifera. M. Cuvier appears to have been in some measure aware of the importance of the distinction when he instituted his order *Pulmonés*, but he afterwards suffered himself to be more influenced by the presence of an operculum, the shape of the aperture of the shell and the supposed separation of the sexes, than by the characters of the respiratory organs.

I. Class.

PULMONIFERA.

The pulmonary cavity is single and lateral. Its
VOL. V. PART II.

Mollusca. orifice is capable of being closed at the will of the animal. The blood-vessels are spread, chiefly on the walls and roof, like delicate net-work.

The reproductive system of the animals of this class exhibits the sexual organs, in general, united in the same individual. Mutual impregnation, however, is necessary. All the species are oviparous. The eggs are either naked, as in the terrestrial genera, or enveloped in a gelatinous mass like the aquatic kinds. The embryo acquires nearly all its members while in the egg, and the shell is of a proportional size previous to hatching. Sir Everard Home, when treating of the distinguishing characters between the ova of the sepia, and those of the vermes testacea, that live in water (*Phil. Trans.* 1817, p. 297), and when referring to the ova of the vermes testacea, says, "If the shell were formed in the ovum, the process of aerating the blood must be very materially interfered with, for this reason, the covering, or shell of the egg, first drops off, and the young is hatched before the shell of the animal is formed; this I have seen take place in the eggs of the garden snail, but in the testacea that live in water, the young requires some defence in the period, between the egg being hatched and the young acquiring its shell, which is not necessary in those that live on land; for this purpose, the ova are enclosed in chambers of a particular kind." The assertion here made, and founded on *a priori* considerations, that the shell is not formed until after the egg is hatched, is opposed by every observation which we have been able to make on the subject; and what is more surprising, it is at variance with his own observations on the garden snail, the very example produced in its confirmation. The eggs of a snail laid on 5th August 1773 were hatched on the 20th of that month, and their condition at this time distinctly stated. "On the 20th, the young were hatched, and the shells completely formed." It is much more becoming, in a philosopher, to observe how nature operates, than to pronounce what she must do.

I. Order.

TERRESTRIAL.

The animals of this order reside constantly on the land. When by accident they fall into the water, they appear to be incapable of using their foot as a sucker or as a fin, and die after a few writhings. The species in general prefer moist places, and seldom are very active in dry weather. After a shower they speedily leave their hiding-places, and at this time they may be readily collected. The eggs are hatched on land.

1. Subdivision.

Cloak and foot parallel, and containing the viscera between them.

In this group are included those animals denominated slugs in this country. They possess four retractile tentacula, of unequal length. The eyes are two in number, in the form of black points, seated at the tips of the posterior tentacula.

1. Tribe.

Cloak furnished with a shield.

Mollusca. The shield is, in general, strengthened internally by a deposition of earthy matter, in the form of grains, or a plate.

A. Shield anterior.

In this group, the shield is placed nearer the head than the tail. It contains four genera, two of which have compound tails, or furnished with peculiar organs, while in the remaining genera the tails are simple.

1. Extremity of the Tail Compound.

Genus, *Arion*.—A mucous orifice at the termination of the cloak.

This genus has been recently instituted by M. le Baron D'Audebard De Férrussac, in his *Histoire Naturelle Générale et Particulière du Mollusques Terrestres et Fluviales*, folio, Paris, 1819, 3e liv. p. 53. The species of which it consists were formerly confounded with those which now constitute the restricted genus *Limax*. It differs, however, in possessing the mucous pore, in the pulmonary orifice being near the anterior margin of the shield, with the sexual orifice underneath, and in the soft state of the calcareous matter in the shield. The author now quoted has described four species, and illustrated their characters by beautiful and expressive figures. The *Limax ater* (together with its variety *rufus*) of British writers may be regarded as the type of the genus.

Genus, *Plectrophorus*.—A conical protuberant shell at the termination of the cloak.

This genus, likewise instituted by M. Ferrussac, nearly resembles the preceding in form. Three species have been described and figured, which, however, differ remarkably from one another.

2. Extremity of the Tail Simple.

The genera of this group have neither a terminal mucous orifice nor shell.

Genus, *Limax*.—Pulmonary orifice near the posterior margin of the shield.

This genus, as now restricted by M. Ferrussac, differs from the *Arion* in the absence of the caudal mucous pore, the position of the pulmonary cavity, and the orifice of the sexual organs placed under the superior right tentaculum. The calcareous matter of the shield is more solid, and appears as a shelly plate. Six species have been described and figured.

The *Limax cinereus* of Lister is the type of the genus.

Genus, *Limacellus*.—Pulmonary orifice near the anterior margin of the shield.

This genus was instituted by M. de Blainville, in the *Journal de Physique*, December 1817, p. 442, pl. 11, f. 5, nov. His observations were made on a specimen in a shrivelled state, preserved in spirits of wine, which was communicated to him from Dr Leach of the British Museum. Its history is, therefore, necessarily imperfect. The animal is rounded before and pointed behind, and dorsally protuberant. The whole body is smooth, soft, and of a greyish white colour. The shield, which adheres on all sides, is destitute of any shelly plate. It is notched near its anterior margin, at the opening of the pulmonary cavity. The foot is broad, and separated

Mollusca. from the cloak by a slight fold, which, on the right side, forms a groove, leading from the base of the right tentaculum to the posterior extremity of the body. It is inferred from this appearance, that the sexual organs are disjoined, the female parts being seated in the tail, while the male organs occupy the ordinary position. The only species, *Limacellus lutescens*, is supposed to have been brought from the Antilles.

B. Shield posterior.

In this group, the shield is placed nearer to the tail than in the preceding, and is fortified internally with a subspiral plate. It contains one genus.

Genus, *Parmacella*.—Posterior extremity of the shield containing the shell.

The pulmonary cavity is placed underneath the shell of the shield. This arrangement occasions a corresponding posterior position to the heart. Along the back, from the shield to the head, are three grooves, the middle one of these is double. The shield itself adheres only at the posterior portion, the anterior part being free. The internal structure is similar to the slugs. The only marked difference, indeed, consists in two conical appendages of the sexual cavity, by which there is an approach to the *Helices*.

The *Parmacella Olivieri* is the only known species, and was first described, and its structure unfolded, by M. Cuvier. It was brought from Mesopotamia by M. Olivier.

2. Tribe.

Cloak destitute of a shield.

In this tribe, the pulmonary cavity is situate near the tail.

A. Tail covered with a single spiral open shell.

Genus, *Testacella*.—Pulmonary cavity underneath the shell.

The vent and pulmonary cavity are from the position of the protecting shell, on which they are dependent, nearly terminal. The foot extends on each side beyond the body. From the manner in which the blood is aerated, the auricle and ventricle are placed longitudinally, the latter being anterior.

This genus at present consists of three species. One of these, *T. hahiotoides*, is a native of France and Spain. It lives in the soil, and feeds on the earthworm. Another species, the *T. Maugei*, was first observed at Teneriffe by M. Mauge. It has been figured in the splendid work on the Mollusca, by Ferrussac, already referred to, Tab. vii. f. 10—12, from specimens found in the botanical garden of Bristol, and communicated by Dr Leach. It has been conjectured, that the British animals may have been introduced along with plants from Teneriffe. The third species, *T. ambiguus*, is established on the doubtful authority of a shell in the collection of M. Lamarck.

B. Destitute of an external shell.

Genus, *Veronicellus*.—Cloak fortified posteriorly by an internal shelly plate. Tentacula four.

This genus was instituted by M. Blainville for the reception of the *V. lavis*, established from a specimen preserved in spirits, belonging to the British Museum, and communicated by Dr Leach. It is figured

Mollusca. by Ferrussac, Tab. vii. Fig. 6, 7. The body is somewhat pointed before, and rounded behind. The cloak is large; the foot rather narrow, and plaited on the edges. The opening to the pulmonary cavity is situated on the right side posteriorly, under the shell. A little in advance of this is another opening, in the middle of which is the funnel-shaped aperture of the anus. The sexual organs are united, and placed at the base of the right tentaculum.

It is not improbable, according to Ferrussac, that the *Limax nudus cinereus terrestris* of Sloane (Jam. ii. p. 190, Tab. cccxxiii, f. 2, 3), may belong to this genus, or rather, that the individual brought home by Sloane may have been the identical specimen submitted to M. Blainville's examination.

Genus, *Onchidium*.—Cloak tuberculated. Snout enlarged and emarginate. Tentacula two in number, with eyes at the tips.

This genus was instituted by Dr Buchanan, in *Lin. Trans.* Vol. V. p. 132, for the reception of a species which he found in Bengal, on the leaves of *Typha Elephantina*. It is not, according to this naturalist, "like many others of the worm kind, an hermaphrodite animal; for the male and female organs of generation are in distinct individuals. I have not yet perceived any mark to distinguish the sexes, while they are not in copulation, as in both, the anus and sexual organs are placed in a perforation (cloaca communis), in the under part of the tail, immediately behind the foot; but during coition, the distinction of sexes is very evident, the penis protruding to a great length, considering the size of the animal."

2. Subdivision.

Cloak and foot parallel; the viscera contained in a spiral dorsal protuberance, protected by a shell.

This group includes the animals usually denominated SNAILS. They bear a very close resemblance to the slugs. The shield, however, has a thickened margin in front, destined to secrete the matter of the shell. In the part corresponding with the centre of the shield in the slugs there is (as Cuvier has characteristically termed it) a *natural rupture*, through which the viscera are protruded into a conical bag twisted spirally. In this bag are contained the principal viscera, the liver occupying its extremity. The body of the animal is attached to the pillar of the shell by a complicated muscle, which shifts its place with the growth of the animal. The mouth is furnished above with a thin-arched corneous mandible, notched on the edges. The whole body, including the foot and head, are, in general, capable of being withdrawn into the cavity of the shell. In one genus, the aperture is closed by a lid.

1. Tribe.

The foot is furnished with a lid or operculum, for closing the mouth of the shell when the animal withdraws itself into the cavity.

Genus, *Cyclostoma*.—Aperture of the shell circular.

The tentacula are linear and subretractile. The primary ones have subglobular, highly-polished extremities, considered by Montague as the eyes. The

true eyes, however, are placed at the exterior base of the large tentacula, and are elevated on tubercles, which are the rudiments of the second pair.

The aperture of the pulmonary cavity is situated on the neck. The sexes are likewise separate; the penis of the male being large, flat, and muscular. The mouth is formed into a kind of proboscis, and the upper lip is deeply emarginate. The *Turbo elegans* of British conchologists is the type of the genus.

2. Tribe.

Foot destitute of a lid.

A. Aperture of the shell with a thickened margin.

In all this division, the margin of the shell, while the animal is young, is thin; but upon reaching a certain period, it becomes thick, and bordered with a ring, after which, there is no increase of size.

1. Last formed Whorl of the Shell greatly larger than the penultimate one.

Genus, *Helix*.—Snail. Aperture of the shell lunulated; the width and length nearly equal.

The snails differ from the slugs chiefly in the organs of reproduction. The *vagina*, previous to its termination in the sexual cavity, is joined by the canal of the vesicle, and by two ducts, each proceeding from a bundle of multifid vesicles. Each bundle consists of a stem or duct, and numerous branches, with blunt terminations. These organs secrete a thin milky fluid, the use of which is unknown.

The species belonging to this genus are numerous, and exhibit, in the form, the markings, and the coverings of the shell, numerous characters for their subdivision.

Genus, *Bulimus*.—Aperture of the shell longer than broad.

The structure of the animals of this genus has not been determined; but analogy would lead us to conclude, that it is similar to the snails. While the shells of the *Helix* are globose, those of *Bulimus* are turrit.

2. Last Whorl nearly of the same size as the penultimate one, or even less.

The genera of this group are already noticed sufficiently in detail, in the article CONCHOLOGY of this Supplement, under the 27 genus, *Turbo*.

B. Aperture of the shell destitute of thickened margin.

There is in this group no certain indication of maturity or stationary growth.

1. Mouth of the Shell at the Pillar entire.

Genus, *Vitrina*.—Margin of the shield double.

The upper fold of the shield is divided into several lobes, which are capable of being reflected over the surface of the shell. The shell itself is not capable of containing the whole body of the animal. The *Helix pellucida* of Muller is the type of the genus. It is a common British species, and was hastily regarded by Montague as the fry of the *Helix lucida*.

Mollusca.

2. Mouth of the Shell at the Pillar effuse.

Genus, *Succinea*.—Termination of the pillar rounded.

The *Helix putris* of British writers is the type of the genus.

Genus, *Achalina*.—The termination of the pillar truncated.

The *Buccinum acicula* of Muller, a native of England, belongs to this genus; and likewise the *Helix octona* of Linnæus, erroneously considered as a native of Britain.

II. Order.

AQUATIC.

The aquatic pulmoniferous gasteropoda have their residence constantly in the water. They possess two tentacula only. These are usually flattened, incapable of being withdrawn, and having eyes at the internal base. The food consists of aquatic plants. Respiration can only take place at the surface of the water, to which the animals occasionally ascend, to expel from the pulmonary cavity the vitiated air, and replenish it with a fresh supply. The sexes are united. The spawn, which is in the form of a rounded gelatinous mass, containing many ova, is deposited on aquatic plants under water. Previous to hatching, the fœtus must be aerated by means of some branchial arrangement.

1. Subdivision.

Body protected externally by a shell.

The animals belonging to this subdivision bear a very close resemblance to the snails, in the structure of their body, and the form of their shell.

1. Tribe.

The protecting shell spirally twisted.

A. Shell turritid.

1. Whorls dextral.

Genus, *Lymncus*.—Aperture of the shell having the right lip joined to the left at the base, and folding back on the pillar.

The tentacula are lanceolate and depressed. The mouth is furnished with three jaws; the lateral ones simple; the upper one crescent-shape, and emarginate. The male and female organs, though intimately connected, internally, have their external orifices separated to a considerable distance, the former issuing under the right tentaculum, the latter at the pulmonary cavity. There are several species natives of Britain.

2. Whorls sinistral.

Genus, *Physa*.—Pillar-lip destitute of a fold.

The external appearance of the animal is similar to the *Lymncus*; but the margin of the cloak is loose, divided into lobes, and capable of being reflected over the surface of the shell near the mouth. This genus was instituted by Draparnaud. The *Bulla fontinalis* of British authors is regarded as the type of the genus.

Genus, *Aplexa*.—Pillar-lip, with a fold.

This genus was instituted by us for the reception of the *Bulla hypnorum* and *rivalis* of British writers. The shell is more produced than in the *physa*. The cloak of the animal is incapable of being reflected on the shell, and its margin is destitute of lobes.

B. Shells depressed.

The spires revolve in nearly the same horizontal line. The tentacula are long, and filiform.

Genus, *Planorbis*.—Cavity of the shell entire.

This is another sinistral genus; the vent, pulmonary cavity, and sexual organs, being on the left, and the heart on the right side. The *P. corneus*, the type of the genus, pours forth, when irritated, a purple fluid from the sides, between the foot and the margin of the cloak.

Genus, *Segmentina*.—Cavity of the shell divided.

Externally, the shell appears similar to planorbis; but internally, it is divided by testaceous transverse partitions into several chambers, which communicate with each other by triradiated apertures. It is uncertain whether the animal is to be considered as dextral or sinistral. This genus was instituted by us several years ago, for the reception of the *Nautilus lacustris* of Lightfoot, first described and figured in *Phil. Trans.* Vol. LXXVI. p. 160. Tab. i. f. 1. 8.

2. Tribe.

Shell simply conical.

Genus, *Ancylus*.—Foot short, elliptical.

The tentacula are short, compressed, and a little truncated. This genus was formed by Geoffroy, and includes the *Patella lacustris* and *oblonga* of British conchologists.

2. Subdivision.

Body destitute of the external protection of a shell.

Genus, *Peronia*.—Head with two long retractile tentacula. The snout is divided into two broad appendages. Between the tentacula, towards the right side, is the opening for the penis. The anus is terminal, immediately above which is the entrance to the pulmonary cavity; and on the right is the opening to the female organs, from which a groove runs towards the right lobe of the snout.

This genus, which we have named in honour of M. Peron, was referred by Cuvier to the *Onchidium* of Buchanan, which we have already noticed, and the species termed *O. Peronii*. It was found creeping upon marine rocks, under water, at the Mauritius, by M. Peron. M. Cuvier conjectures that it breathes free air, and has accordingly inserted it among the *Pulmones aquatique*. Some doubts, however, may reasonably be entertained about the truth of this supposition. It would certainly be an unexpected occurrence to find a marine gasteropodous mollusca obliged to come to the surface at intervals to respire. It will probably be found that it is truly branchiferous.

II. Class.

BRANCHIFERA.

The molluscos animals of this class are more numerous than those of the preceding. They chiefly

Mollusca.

Mollusca. inhabit the waters of the ocean, a few genera only being met with in fresh water lakes and rivers. The branchiæ which constitute their aerating organs exhibit numerous varieties of form, position, and protection, and furnish valuable characters for their methodical distribution.

I. Order.

BRANCHIÆ EXTERNAL.

The branchiæ are pedunculated, and more or less plumose. They are moveable at the will of the animal, and in general are capable of great alteration of form.

1. Tribe.

Branchiæ exposed.

In nearly all the genera the branchiæ are numerous, and distributed regularly over the cloaks or sides.

A. Branchiæ issuing from the cloak dorsally.

1. Body exposed, and destitute of a shell.

In many species the back is covered with perforated papillæ, which pour out a mucous secretion. All the species are hermaphrodite, with reciprocal impregnation.

a. Anus situate near the posterior extremity of the back, and surrounded with a fringe of plumose branchiæ.

Genus, *Doris*.—Oral tentacula two; vent without scales.

The cloak is covered with retractile papillæ, and separated from the foot by a distinct duplicature. Towards its anterior margin are placed the two superior tentacula. These are retractile, surrounded at the base with a short sheath, and supported on a slender stem, having an enlarged compound plicated summit. The neck is short, and above the mouth there is a small projecting membrane, connected at each side with the oral tentacula, which are in general minute, and of difficult detection.

The following species are natives of the British seas: 1. *D. Argo*; 2. *verrucosa*; 3. *lævis*; 4. *marginala*; 5. *nodosa*; 6. *quadricornis*; 7. *nigricans*.

Genus, *Polycera*.—Oral tentacula more than two.

The branchiæ, when withdrawn, are protected by two scales. The superior tentacula resemble those of the *Doris*, the oral ones are more numerous, sometimes amounting to six. *P. flava* and *pennigera* are British examples.

b. Anus situate on the right side, and unconnected with the branchiæ.

(A.) Mouth furnished with corneous jaws.

These jaws are in the form of narrow plates, which cut the food by crossing each other like the blades of a pair of scissors.

(1.) Branchiæ disposed along the back or sides, and unconnected with membranaceous expansions.

(a.) Tentacula limited to two in number.

Genus, *Tergipes*.—Branchiæ furnished with sheaths at the base.

The branchiæ form a single row on each side, and are qualified to act as suckers. The *Limax tergipes* of Forskael, *Des. An.* p. 99, is the type of the genus. *T. maculata*, described by Montagu, *Lin. Trans.* VII. p. 80, T. vii. f. 8, 9, is a British example.

Genus, *Tritonia*.—Branchiæ destitute of basilar sheaths.

The branchiæ are in the form of plumes, or imbricated productions, placed in a row on each side the back. The tentacula, which are partially retractile, have a sheath at the base. In some of the species there are indications of eyes. The *T. arborescens*, *pinnatifida*, and *bifida*, are examples of British species.

(b.) Tentacula four in number.

The branchiæ are simple, tapering, or clavate, and disposed in transverse rows on each side. These branchiæ in some species readily fall off, and are capable of swimming about in the water for a short time, as if independent. This is executed by means of minute hairs with which their surface is covered, and which move rapidly, pushing forward the distal extremity.

Genus, *Montagua*.—Branchiæ in continuous rows across the back.

This genus, which differs from the other not merely in the arrangement of the branchiæ, but in possessing a cluster of short papillæ on the right side, probably connected with the anus, we have ventured to name in honour of the late George Montagu, the well-known author of *Testacea Britannica*, and of several valuable papers in the *Linnean Transactions*, on molluscous animals. The two species which may be referred to this genus were detected in Devonshire by this observer. The first, *M. longicornis*, *Lin. Trans.* Vol. IX. p. 107. Tab. vii. f. 1, is the type of the genus. The other species, *M. carulea*, *Lin. Trans.* Vol. VII. p. 78. Tab. vii. f. 4, 5, is probably the type of another genus.

Genus, *Eolida*.—Branchiæ interrupted on the back.

This genus, which was instituted by M. Cuvier, includes the following British examples: 1. *E. papillosa*; 2. *plumosa*; 3. *pedata*; 4. *purpuriscens*.

(2.) Branchiæ disposed on lateral membranaceous expansions.

These expansions serve the double purpose of supporting the branchiæ, and acting as fins.

Genus, *Scyllea*.—Branchiæ seated dorsally on the fins. Tentacula two.

On each side of the back are two membranaceous expansions, and one on the tail, supporting on their dorsal surface scattered plumose branchiæ. The tentacula are each furnished with a large funnel-shaped sheath. The foot is very narrow, with a mesial groove, used in climbing up the stalks of seaweeds. The mouth is placed at the base of the tentacula, and surrounded with a semicircular lip. The tongue is in the form of a tubercle, with reflected points. The gullet is plaited longitudinally. The stomach is short and cylindrical, with a ring of hard longitudinal scales. The liver consists of six unequal globules, and the bile is poured into the cardiac extremity of the gullet. The *Scyllea pelagica* has been long known to naturalists, and appears to

Mollusca. be very common in the equatorial seas, adhering to the stems of the *Fucus natans*.

Genus, *Glaucus*.—Branchiæ seated on the margin of the fins. Four simple tentacula.

On each side of the body there are three or four membranaceous expansions, the margins of which are fringed with the simple branchial filaments. This genus was instituted by R. Forster, and the oldest known species, *G. radiatus*, is figured, *Phil. Trans.* Vol. LIII. Tab. iii.

(B.) Mouth destitute of corneous jaws.

Genus, *Thethys*.—Branchiæ forming a row on each side the back, consisting of fringed processes, alternately larger and smaller.

The *T. fimbria* is the type of the genus, a figure of which, with its anatomical details, is given by M. Cuvier, in his *Mémoire sur le Genre Thethys*.

2. Body concealed in a Spiral Shell.

This section includes the genus *Valvata* of Muller, represented by two British species, *V. cristata* (*Helix cristata* of Montagu) and *V. piscinulis* (*Turbo fontinalis*). These resemble in aspect the aquatic pulmoniferous gasteropoda. The branchiæ appear in the form of a feather, with a central stem, and a row of compound branches on each side, decreasing in size from the base to the free extremity. It issues from the neck near the middle, a short way behind the anterior tentacula. Near this plume, but towards the right side, is a single simple filament, like a tentaculum. The anterior tentacula occupy the usual position, are setaceous, and have the eyes placed at the base behind. The spiral shell is capable of containing the body, and the aperture can be closed by a spirally striated operculum attached to the foot. The internal structure is unknown.

B. Branchiæ issuing laterally from between the cloak and foot.

This division includes the orders *Cyclo-branchia* and *Infero-branchia* of Cuvier, which we have ventured to bring together, as connected by the common character of the position of the gills.

1. Body protected dorsally by a shelly covering. *Cyclobbranchia*.

a. Shell simple.

Genus, *Patella*.—Shell entire. Mouth with tentacula.

The species belonging to this genus are numerous, and appear to admit of distribution into sections; the first having the branchial circle complete, the second interrupted.

b. Shell divided.

Genus, *Chiton*.—Shell constituting a series of imbricated dorsal plates.

The body is elliptical. The cloak is firm and cartilaginous, and variously marked on the margin. The dorsal plates are arched, and occupy the middle and sides of the back, where they are implanted in the cloak, in an imbricated manner, the posterior margin of the first valve covering the anterior of the second. The foot is narrow. The mouth is sur-

rounded with a semicircular curled membrane, and is destitute of tentacula. The anus consists of a short tube, placed at the posterior extremity of the cloak. The external orifice of generation has not been detected.

Genus, *Chitonellus*.—Dorsal plates not imbricated.

In this genus, instituted by Lamarck (*Hist. Nat. des Animaux sans Vertèbres*, Vol. VI. p. 316), the shells are slender, narrow, and are disposed longitudinally, and not in contact, along the middle of the back, leaving the sides of the cloak naked. Two species, *C. lævis* and *striatus*, were brought from New Holland, by Peron and Le Sueur.

2. Body naked. *Inferobranchia*.

Genus, *Phyllidia*.—Anus placed dorsally near the extremity of the cloak.

M. Cuvier has given descriptions of three from the tropical seas, which differ remarkably in the protuberances of the cloak.

Genus, *Diphyllidia*.—Anus placed on the right side.

This genus was formed by M. Cuvier in his *Regne Animal*, Vol. III. p. 395, from an imperfectly investigated animal, in the cabinet of M. Brugmans at Leyden. The cloak is pointed behind, with a feeler and small tubercle on each side.

2. Tribe.

Branchiæ simple, and concealed when at rest under a lid. *Tectibranchia* of Cuvier.

A. Head furnished with tentacula.

1. Tentacula four in number.

a. Branchiæ lateral.

Genus, *Aplysia*.—Branchiæ with a corneous lid.

The *A. depilans*, the type of the genus, is of frequent occurrence on the British shores. The *A. punctata* of Cuvier may be regarded merely as a variety.

It is probably at this place where the genus *Gasteroplax* of Blainville, published by Lamarck, under the ill-judged title *Umbrella* (*Hist. Nat. &c.* Vol. VI. p. 339), should be introduced. The following is the extended character which he has communicated.

"Corpus valde crassum, obovatum, testa dorsali onustum; pede amplissimo, subtus plano, undique prominente, anterieus sinu emarginato, postice attenuato. Caput non distinctum. Cavitas infundibuliformis in sinu antico pedis os in fundo recondens. Tentacula quatuor: superiora duo, crassa, brevia, truncata, hinc fissa, intus transversim sublamellosa; altera duo, tenuia, cristata, pedicellata, ad oris latera. Branchiæ foliaceæ, serratim ordinatæ, infra cutis marginem per totam longitudinem lateris dextræ. Anus post extremitatem posticam branchiarum.

"Testa externa, orbicularis, subirregularis, planulata, superne convexiuscula, albida, versus medium mucrone apicali brevissimo præbita; marginibus acutis: interna facie subconca; disco calloso, colorato, ad centrum impresso, limbo lævi cincto."

Doubts seem to be entertained whether the shell is to be considered as belonging to the cloak or the foot. Two species are known.

Mollusca.

Genus, *Notarchus*.—Lid of the branchiæ soft. There is an oblique groove from the neck leading to the branchiæ. The structure is similar to *Aplysia*. M. Cuvier instituted this genus in his *Regne An.* Vol. II. p. 395, and Vol. IV. Tab. xi. f. 1.

b. Branchiæ terminal.

Genus, *Dolabella*.—Dorsal plate a solid shell.

2. *Tentacula two in number.*

Genus, *Pleurobranchus*.—Cloak and foot expanded, between which, on the middle of the right side, the branchiæ are placed.

B. Head destitute of tentacula.

Genus, *Bulla*.—Body of the animal protected by a convoluted shell.

M. Lamarck is inclined to divide this genus into two, distinguishing those in which the shell is concealed, by the term *Bullæ*, from such as have the shell in part exposed, which he retains in the genus *Bulla*. The shells of the genus *Bullæ* are thin and white, as *B. aperta*; those of *Bulla* stronger, more opaque, and covered with an epidermis, which, after the death of the animal, is easily detached, as *B. lignaria*.

Genus, *Doridium* (of Meke).—Destitute of a dorsal plate or shell.

There is a cavity in the cloak, with a spiral turn. The branchiæ, and accompanying organs, are placed far behind. There is here no appearance of a spinous tongue; the gullet is simple, and the stomach is membranaceous. *D. carnosum*, a native of the Mediterranean, is the type of the genus.

II. Order.

BRANCHIÆ INTERNAL.

These aerating organs are contained in a cavity, and appear in the form of sessile pectinated ridges.

1. *Subdivision.*

Heart entire, and detached from the rectum.

This group, forming the *Pectinobranchia* of Cuvier, includes nearly all the marine gasteropoda which have spiral univalve shells. It likewise contains a few species which inhabit the fresh water.

1. *Tribe.*

Shell external.

The shelly covering exhibits all the variations of the spiral form. The internal structure has hitherto been in a great measure neglected, so that the characters, employed in the methodical distribution of the species and genera, are derived from the shelly appendage of the cloak. The groups, therefore, are merely artificial temporary combinations.

A. Aperture of the shell entire.

As co-existent with this character of the shell, the anterior margin of the cloak, at the entrance to the branchial cavity, is found likewise to be entire.

1. *Aperture of the shell closed by a pedal lid, or operculum.*

The three following families appear to be the indications of as many natural groups, the genera of which admit of still more minute arrangement.

1. Family, *Turbonidæ*.—Aperture of the shell round or ovate.

This family includes the greater number of the species of the Linnean genus *Turbo*. The genera into which it is now divided may be distributed into two sections, from the residence of the animals.

1. Section, *Marine.*

The marine turbonidæ are of frequent occurrence, and compose the genera *Turbo*, *Delphinula*, *Turritella*, *Scalaria*, *Odostomia*, *Monodonta*, *Phasianella*, and *Vermicularia*. Some of the species are known to be ovoviparous, and it is probable that the same kind of reproduction prevails in all of them. Remarkable differences may be observed in the form of the hood, the length of the peduncles supporting the eyes, and the number and distribution of the filaments surrounding the body.

2. Section, *Fluviatile.*

The fluviatile turbonidæ are limited in their number both in regard to genera and species. The genera are only three, *Ampullaria*, *Melania*, and *Paludina*. In the last of these, including the *Helix vivipara* and *tentaculata*, the sexes are distinct in different individuals.

2. Family, *Neritadæ*.—Aperture semicircular, with an oblique straight pillar-lip.

1. Section, *Marine.*

This includes the genera *Nerita* and *Natica*.

2. Section, *Fluviatile.*

This contains only the genus *Neritina*, including *Nerita fluviatilis* of Linnæus.

3. Family, *Trochusidæ*.—Aperture of the shell subquadrangular.

All the genera, including *Trochus*, *Solarium*, and *Pyramidella*, are marine. The cloak on each side is usually ornamented with three filaments.

2. *Aperture of the shell exposed*.—The foot destitute of a lid. Marine.

Genus, *Janthina*.—Foot with an adhering spongy body.

In this genus, represented by the *Helix Janthina* of Linnæus, the spongy body is capable of changing its dimensions, and enabling the animal to sink or rise in the water at pleasure. When irritated, it ejects a purple fluid from the cellular margin of the cloak above the gills, not unlike the *Aplysia*.

Genus, *Velutina*.—Foot simple.

This genus was formed by us for the reception of the *Bulla velutina* of Muller (*Zool. Dan.* Tab. ci. f. 1, 2, 3, 4), the *Helix lævigata* of British writers.

B. Anterior margin of the aperture of the shell canalculated.

This groove in the aperture of the shell is produced by the anterior margin of the cloak being extended over the opening into the gills, for the purpose of acting like a tube or syphon, in conveying the water to and from the branchial cavity. The species are considered as oviparous, with distinct sexes in separate individuals.

1. *Shell convoluted*.—The shell has a lengthened

Mollusca.

mouth parallel with its length. The whorls, which are small segments of large circles, are wrapped round the pillar, and rising little the one above the other, embrace or enclose the preceding ones. The four following families appear to belong to this division.

1. Family, *Conusidae*.—Furnished with a long proboscis, and produced tentacula, with the eyes near the summit on the outside. The genera *Conus* and *Terebellum* form this family.

2. Family, *Cypreadæ*.—Cloak enlarged, and capable of folding over the shell. There is no lid. The genus *Cyprea* is the type.

3. Family, *Ovuladæ*.—Both extremities of the aperture canaliculated. The inhabitants of all the genera, *Ovula*, *Calpurna*, and *Volva*, are unknown. The last genus includes the *Bulla patula* of Pennant.

4. Family, *Volutadæ*.—Canal of the aperture abbreviated. Pillar-lip plaited. The foot appears to be destitute of a lid. The genera are numerous. *Voluta*, *Oliva*, *Cymbium*, *Marginella*, *Cancellaria*, *Mitra*, *Ancilla*, *Volvaria*, and *Tornatella*. The last genus contains the *Voluta tornatilis* of British writers.

2. *Shell turrited*.—The whorls of the shell, the revolving spire of which is subconical, scarcely embrace one another, but are merely united at the margins. Three families may here be established.

1. Family, *Buccinidæ*.—Canal short, scarcely produced beyond the anterior margin of the lip, and bent towards the right. The tentacula are remote, and the head is destitute of a hood. The mouth has a retractile proboscis. The following genera belong to this family: *Buccinum*, *Eburna*, *Dolium*, *Harpa*, *Nassa*, *Purpura*, *Cassis*, *Morio*, and *Terebra*.

2. Family, *Muricedæ*.—Canal produced, and straight. The tentacula approach. The head and mouth as in the preceding family. The genera are, *Murex*, *Typhis*, *Ranella*, *Fusus*, *Pleurotoma*, *Pyrula*, *Fasciolaria*, and *Turbinella*.

3. Family, *Cerithiadæ*.—Canal short and recurved. Head with a hood. This family contains the marine genus *Cerithium*, and the fluviatile one *Potamidum*.

4. Family, *Strombusidæ*.—Canal short, and bent towards the right. The outer margin of the aperture becomes palmated with age, and exhibits a second canal, generally near the former, for the passage of the head. The following are the genera: *Strombus*, *Pterocera*, and *Rostellaria*.

2. Tribe.

Shell internal.

This tribe consists at present of only one genus, termed *Sigaretus*, two species of which are natives of Britain.

2. Subdivision.

Heart traversed by the rectum.

This group includes the order *Scutibranchia* of Cuvier. In general form, and in structure and position of the branchiæ, the resemblance is very close to the genera of the preceding subdivision. They differ, however, in many particulars. The heart is furnished with two auricles, and is perforated by the intestine. The sexes appear to be incorporated in the same individual, or rather the male

organs are unknown. The body is protected by a shell, the aperture of which is wide, and never closed by a lid. Mollusca.

1. Tribe.

Shell ear-shaped, flat, with a lateral, and nearly concealed spire.

Family, *Haliotidæ*, including the genera *Haliotis*, *Padola*, and *Stomatia*. These genera exhibit well-marked characters in the shell. The left margin of the shell in *Haliotis* is pierced by a row of holes. In *Padola*, these holes are nearly obliterated; but there is an internal groove and external ridge in the line of their direction. In *Stomatia*, there are neither holes nor ridges.

2. Tribe.

Shell conical, simple, or slightly revolute at the apex:

A. Cavity of the shell interrupted by a testaceous plate. This division consists of three genera, each of which may be regarded as the type of a family, although, for the present, they all be included in one.

Family, *Crepiduladæ*.—The marine genera are, *Crepidula* and *Calyptra*, the latter including the *Patella Chinensis* of British writers. There is only one fluviatile genus, termed *Navicella*.

B. Cavity of the shell entire.

1. Family, *Capulusidæ*.—Shell entire.

This includes the genera *Capulus* (containing *Patella Hungarica* and *antiquata* of British writers) and *Carinaria*, represented by the *Argonauta vitru*.

2. Family, *Fissurelladæ*.—Shell with a slit, or perforation.

In the *Fissurella*, the apex of the shell is perforated. In *Emarginula*, there is a slit in the anterior

II. DIVISION.

MOLLUSCA ACEPHALA.

Destitute of a distinct head or neck.

The animals of this division are much more simple in their organization than those of the preceding division. In none of the species are there any rudiments of organs of hearing or of sight. They are destitute of jaws or other hard parts about the mouth. They all inhabit the water, and possess branchiæ. The organs of the two sexes are incorporated in the same individual, and reciprocal union is unnecessary. They are either oviparous or ovoviviparous. The presence or absence of a shelly covering furnish characters for a twofold distribution of the groups.

1. Section.

ACEPHALA CONCHIFERA.

The shell, which in all cases is external, is bivalve, and exhibits very remarkable differences in the form

Mollusca. relative size, and connection of the valves. The cloak is likewise in the form of two leaves, corresponding with the valves which protect it.

1. Order.

BRACHIOPODA.

Mouth with a spiral arm on each side fringed with filaments.

The genera included in this group constitute the Brachiopoda of Cuvier. The lobes of the cloak are free anteriorly. From the body, between the lobes, the arms have their origin, at the margin of the mouth. These arms are capable of folding up spirally. All the species are permanently attached to foreign bodies, and inhabit the sea. Their nervous and reproductive systems have received but little elucidation.

1. Subdivision.

Shell supported on a fleshy peduncle.

Genus, *Lingula*.—Valves equal, the apex of both attached to the peduncle.

The peduncle is nearly cylindrical, cartilaginous, and covered with a membrane consisting of circular fibres. The valves are oval, flat, and destitute of teeth, or elastic ligaments. The adductor muscles are numerous, obliquely placed, and appear capable of giving to the valves a considerable degree of lateral motion. The cloak is thin, and has interspersed muscular fibres. Its margin is thickened, and fringed with fine hairs of nearly equal length.

The *Lingula unguis* is the only known species, the structure of which has been developed by Cuvier.

Genus, *Terebratula*.—Valves unequal, the peduncle passing through an aperture in the largest valve.

The arms are shorter than those of the *Lingula*, and are said to be forked. They are supported within by numerous arcuated plates.

M. Lamarck divides the recent kinds into two sections. 1. *Shell smooth, or destitute of longitudinal ribs*. The *T. cranium*, a native of the Zetland seas, may be quoted as an example. The peduncle is simple. 2. *Shell ribbed longitudinally*. The *T. aurita*, which inhabits Loch Broom, is another, though recently discovered, British example. The larger valve is broadest in the middle, semicircular in front, and narrowing towards the apex, in consequence of the sides being compressed or bent inwards. The ribs from the beak towards the anterior margin are the most distinct, rounded, and about eight in number; those towards the sides are obsolete. The under valve is nearly orbicular, with the margin at the hinge truncated, or rather obtusely angular, and having the sides depressed, and forming small auricles, as in the genus *Pecten*, but not produced. The ribs are absolutely wrinkled across, and the margin is waved by the ribs being concave internally. The inner surface of both valves, especially the largest, is finely punctulated. The hinge is formed by a projection on each side, the proximal margin of the perforation in the large valve entering corresponding depressions in the smaller one. The margin of the perforation itself is completed by the application of the smaller valve. The peduncle is short, and consists of numerous un-

equal-sized tubular threads, attached by a complicated tendino-muscular apparatus, chiefly to the larger valve. The spiral arms seemed to have simple summits, and to be destitute of testaceous plates. The smallness and probable youth of the subject, however, rendered minute examination of the structure impracticable. Trawled up in Loch Broom, near the harbour of Stornoway, 16th August 1821. This species approaches nearest to the *T. truncata*.

The fossil species of this genus are numerous, and occur in the older and newer of the floetz formations. They furnish obvious characters for the construction of many genera, some of which have been already established.

2. Subdivision.

Shell sessile.

Genus, *Criopus*.—Under valve cemented to stones.

The under valve is membranaceous, flat, and adhering; the upper is flatly conical, and resembles a patella, in which genus, from neglecting the structure of the animal, it has usually been placed.

The *C. anomalus*, *Patella anomala* of Muller, *Zool. Dan.* Tab. v. f. 1, 8, has a branched double ovium, with round eggs. It has been described and figured as a native of the Zetland seas, under the term *Patella distorta*, in *Edin. Encyclopædia*, Vol. VII. p. 65, Tab. cciv. f. 4; and *Lin. Trans.* Vol. XI. p. 195, Tab. xiii. f. 5.

II. Order.

BIVALVIA.

Mouth destitute of fringed spiral arms.

The animals of this group form the class *Coquifera* of Lamarck, the *Bivalvia* of the older naturalists.

The shells exhibit great variety of form and relative size. They are joined together at the hinge, which is either plain or toothed, and corresponds in position with the back of the animal. The connection of the two valves is secured by the intervention of an elastic horny *ligament*, the office of which is to keep the valves open. It is either external or internal. The valves are closed by means of *adductor muscles*, intermixed with tendons, and, passing transversely through the animal, adhere to the corresponding places in the inside of each shell. By the contractions of these muscles the free edges of the valves are brought into contact, at the same time that the ligament is compressed or stretched, according as it is internal or external. The number of muscular impressions is employed by Lamarck in the division of the *Bivalvia* into two orders, *Dimyaires* and *Monomyaires*. This distinction, however, he has not attended to with care, as in his family *Mytilacées*, which he includes in his second order, or those having one adductor muscle, there are obviously two adductor muscles, although the one is certainly much larger and more complicated than the other. Besides these impressions of the adductor muscles, there are others connected with the foot and byssus. The cloak lines the inside of the shells. In some cases it is entirely open, when the border corresponding with the free margin of the shell is thickened, and more or less fringed with contractile irritable filaments. In other cases the cloak in front is more or less united, and

Mollusca. even forms tubular elongations, which are termed *syphons*.

Locomotion is denied to many species of this order. Among these some are immoveably cemented to rocks and stones, as oysters; a few are attached by a cartilaginous ligament, as the *Anomix*; while others are fixed by means of a *byssus*. This last organ consists of numerous filaments issuing from a complicated apparatus in the breast, connected with a secreting gland and with the shell by the intervention of tendinous bands. The *foot* is seated a little towards the mouth, is usually tongue-shaped, capable of considerable elongation, with a furrow on its posterior surface. This organ, where a *byssus* is present, is considered as employed in opening and fixing the threads. When there is no *byssus*, it either acts as a sucker, enabling the animal to crawl among the surface of bodies, or as a paw, to dig holes in the sand or mud. None of the species can float in the water. They either crawl or leap, the last kind of motion being effected by suddenly opening and shutting the valves. In securing a residence, some of the species *bore* into different substances by means of a rotatory motion of the shell. It was at one time supposed that the dwelling was formed by a secretion affecting the solution of the surrounding substance. But the very different substances penetrated by the same species, as limestone, slate-clay, and wood, forbid us to entertain such a supposition.

The nervous system is here but little developed. The superior and inferior ganglia, surrounding the gullet, give rise to all the nervous filaments which proceed through the body.

The digestive organs are scarcely less simple. The food is soft and swallowed entire, and either brought to the mouth by accident, or by eddies produced in the water, by the opening and shutting of the shells, aided in some cases by the syphons.

It may be proper here to state, in order to understand the relative situation of the parts, that, upon laying the animal upon its back, and opening the cloak, the abdomen appears to occupy the middle longitudinally, and the branchia to be arranged on each side. The mouth is situated at the anterior extremity, and consists of a simple aperture entering into the gullet, or rather stomach. It is surrounded by four flattened moveable tentacula, two of which in some are in part united with the cloak, while in others they are free to the base. In their structure they resemble the branchiæ. The stomach is full of cells, the bottom of each pierced with a biliary duct. A singular organ, termed the *crystalline process*, cylindrical, cartilaginous, and transparent, is found in some species projecting into the cavity of the stomach. The liver is large, surrounds the stomach, and pours out its contents by numerous openings. The intestine terminates posteriorly by a tubular anus.

The branchiæ consist of two ribbands on each side, extending the length of the body, free on the sides and margin, and striated transversely. These plates are frequently of unequal size. The blood is brought to these by means of pulmonic veins, without the intervention of the heart. The aerated blood is transmitted to a systemic heart, consisting of one or two auricles, and a ventricle.

The reproductive organs of the *Bivalvia*, hitherto

Mollusca. examined, consist of an ovarium occupying the sides of the body, and penetrating the membranes of the cloak. They appear to have the organs of both sexes incorporated, and to propagate without intercourse. Lamarck is disposed to consider impregnation produced by the male fluid dispersed through the water; a supposition unsupported even by analogy in the animal kingdom. Many species are ovoviviparous; in which case the eggs when ripe pass into the gills, where they are hatched.

The methodical distribution of the *Bivalvia* appears to be attended with peculiar difficulties, in consequence of the uniformity which prevails in the structure and disposition of their organs. The characters furnished by the shell, though useful in the construction of generic as well as specific distinctions, have been abandoned by those who prefer a knowledge of the structure, rather than the form of an animal. The characters derived from the presence of a *byssus*, a *foot*, or *syphons*, appear to be nearly of co-ordinate importance. M. Cuvier gives the preference to those founded on the appearances of the latter, and distributes the genera into five families, an arrangement which we here propose to follow. These, however, may be considered as occupying a much higher rank, and each as including numerous families.

1. *Subdivision*.

Cloak open.

There are no syphons, the anterior margin of the cloak being as open as the mouth of the shell. When the valves open, the water comes immediately in contact with the branchiæ and mouth. The margin of the mantle has a double fringe of filaments.

1. *Tribe*.

Valves closed by one adductor muscle.

A. *Pectenidæ*. Animals free or fixed only by a *byssus*. Furnished with a *foot*.

Into this family, contemplated by Lamarck, the following ill assorted genera may be placed: *Pecten*, *Lima*, *Pedum*, *Plicatula*, *Vulsella*, *Placuna*, *Gryphæa*, *Perna*, and *Crenatula*.

B. *Ostreidæ*. Shell cemented to foreign bodies. Body destitute of a *foot*.

To this family the following genera are related: *Ostrea*, *Spondylus*, and *Anomia*. The last genus ought to form a family apart.

2. *Tribe*.

Shell closed by two adductor muscles.

The two genera, *Avicula* and *Meleagrina* (of Lamarck), form one family of this tribe; the genus *Pinna* another; and the *Arcadæ* a third, including *Arca*, *Pectunculus*, *Nucula*, *Cucullæa*, *Trigonia*, and *Castalia*.

2. *Subdivision*.

Cloak more or less closed, forming syphons.

The further division of this group depends on the modifications of the syphons, or aperture of the cloak.

1. *Tribe*.

The union of the cloak forming only one syphon. This is situate posteriorly opposite the anus, and serves for the purpose of the excrements. The other

Mollusca. large opening allows the water to enter to the mouth and gills.

This tribe may be divided into two families. The first, *Mytilusidæ*, will include the genera *Mytilus*, *Modiolus*, and *Lithodomus*, which are furnished with a byssus. The second, *Uniodæ*, will embrace *Unio*, *Ilyria*, *Anodonta*, and *Iridina*. They want a byssus.

M. Cuvier is disposed to place in this group the genera *Cardita*, *Venericardia*, and *Crassatella*.

2. Tribe.

Cloak closed posteriorly, and anteriorly forming three apertures. The first serves for the passage of the byssus, and is the largest. The second admits water to the branchiæ and mouth: and the third is opposite the anus. The valves are closed by one adductor muscle. There are only two genera belonging to this tribe, *Tridacna* and *Hippopus*.

In the two remaining tribes there are three openings in the cloak. Two of these are posterior, and near each other; sometimes, indeed, they are tubular and united. There is no byssus, but always a foot.

3. Tribe.

Anterior opening large, allowing the water free access to the mouth and gills, and the feet freedom of motion. The structure of the animals is yet too imperfectly examined, to enable any one to establish families on permanent characters. The attempt which Lamarck has made may be considered as a complete failure, independent of the wanton changes of nomenclature with which it is chargeable. The following are the principal genera belonging to this tribe: *Chama*, *Isocardia*, *Cardium*, *Donax*, *Cyclas*, *Corbis*, *Tellina*, *Loripes*, *Lucina*, *Venus*, *Capsa*, *Petricola*, *Corbula*, and *Mactra*.

4. Tribe.

Anterior opening small, and not exposing the mouth or gills.

In this tribe the mantle is closed in front; and even when the valves are open, neither mouth nor gills are visible. The anterior opening serves for a passage to the foot, and the posterior openings, in the form of two long tubes, united by a common membrane, serve for the entrance and exit of the water to the mouth and branchiæ, and the ejection of the fæces, the dorsal syphon serving the latter purpose. The cuticle of the shell covers also the exposed portion of the cloak, so that, when the animal is removed from the shell, it remains as a loose membrane on the margin of the valves, as was first observed by Reaumur. All the genera prefer concealment, burrowing in sand, mud, or wood, with the head downwards, and the syphons rising to the surface. The following genera belong to this tribe: *Mya*, *Lutraria*, *Anatina*, *Glycemeris*, *Panopæa*, *Pandora*, *Gastrochena*, *Byssomia*, *Hiatella*, *Solen*, *Sanguinolaria*, *Pholas*, *Teredo*, and *Fistularia*.

II. Section.

ACEPHALA TUNICATA.

Covering soft or coriaceous:

The formation of this interesting group of animals

was first publicly announced by Lamarck in his *Histoire Naturelle des Animaux sans Vertèbres*, Tom. III. p. 80 (1816). The labours of Desmaret, Lesueur, and Cuvier, aided by the descriptions of Ellis and Pallas, paved the way for the masterly efforts of Savigny, to whom we owe the most extensive, new, and accurate information yet given concerning the animals of this group. His observations are contained in his *Recherches Anatomiques sur les Ascidies composées, et sur les Ascidies simples*, inserted in his *Mémoires sur les Animaux sans Vertèbres*. 8vo. Paris, 1816.

The covering of the animals of this group consists of an external and internal sac or tunic, which are either entirely united or unconnected, except at the apertures. The surface is smooth in some, and rough in others, and in a few species defended by an artificial covering of agglutinated shells and sand. The sacs are furnished with muscular bands, and are capable of contraction. Some of the species, by means of contractile movements, float about in the water; others, receiving that element into the branchial cavity, and ejecting it forcibly at the opposite one, push themselves forward. Many, however, are fixed during life to seaweeds and stones.

The apertures of the tunic are two in number, unless in the doubtful genus *Mammaria*. The one, frequently the largest, is destined for receiving the water into the cavity to supply the mouth and gills. This is termed the *branchial* cavity. The other is destined for the exit of the water, the eggs, and the fæces, and termed the *anal* opening. These apertures are sometimes placed near each other, at other times at opposite extremities of the body, and variously provided with tentacula or valves.

The mouth is simple, destitute of spiral arms, and opening in the interior of the cavity of the body between the branchiæ, as in the other *Acephala*. It possesses neither jaws nor tentacula. The alimentary canal is very simple, and can scarcely be distinguished into gullet, stomach, and intestine. The food is soft, and such as the bounty of the waves bestows. The liver adheres to the stomach, and in many species is divided into distinct lobes.

The circulating system appears to be reduced to a single systemic ventricle. The gills cover the walls of the cavity, in the form of ridges, more or less complicated, and seldom symmetrical.

The reproductive organs consist of an ovary, either simple or complicated, with some additional glands, the uses of which have not been ascertained. They are considered as hermaphrodite, and independent of reciprocal impregnation. They appear not only to be oviparous, but to be gemmiparous and compound, many individuals being organically connected, and capable of simultaneous movements. They are all inhabitants of the sea.

1. Subdivision.

Interior tunic detached from the external one, and united only at the two orifices.

The branchiæ are large, equal, and spread on the central walls of the inner sac. The branchial orifice has an inner membranaceous denticulated ring, or a circle of tentacula.

1. Tribe.

Body permanently fixed to other bodies.

In this tribe the branchial and anal orifices are not opposite each other, and do not communicate through the branchial cavity. This cavity at its opening is furnished with tentacular filaments. The branchiæ are conjoined anteriorly.

A. Simple.

This division includes the genus *Ascidia* of Linnæus. The individuals are independent of each other, and although they frequently adheret together in clusters, they are destitute of a common covering, or organical connection.

1. Apertures furnished with four rays.

The animals of this group have the external tunic coriaceous, dry, opaque, rough, folded, and frequently covered with extraneous bodies, or inclosing such. The branchial orifice has four rays, the anal one the same, or divided transversely. The branchiæ are divided longitudinally into persistent regular deep folds.

a. Body pedunculated.

The peduncle, in this division, may be said to have its rise in the summit of the body, which it serves to suspend. The abdomen is lateral. The meshes of the branchiæ are destitute of papillæ.

Genus, *Bollenia*.—The tentacular filaments of the branchial circle are compound. There is no liver, and the ovarium is compound. Only one species is known, *B. fusiforme*. Savigny, *Mém. Tab. i. f. 1.* and *Tab. v. f. 5.* It is the *Vorticella Bolleni* of Lin. and the *Ascidia clavata* of Shaw.

b. Body sessile.

M. Savigny describes this group as a genus, which he terms *Cynthia*, which he divides into four subgenera.

(A.) Tentacular filaments of the branchial orifice compound. The folds of the branchiæ more than eight in number. The liver distinct, and surrounding the stomach. Ovarium divided, with one division at least on each side the body. The intestine destitute of a rib.

Genus, *Cynthia*.—Meshes of the branchiæ unchanged by the folds. *C. Momus*. Sav. *Tab. i. f. 2.*

Genus, *Casira*.—Meshes of the branchiæ interrupted by the folds. *C. Diona* of Sav. *Tab. vii. f. 1.* The *Ascidia quadridentata* of Forskael.

(B.) Tentacular filaments of the branchial orifice simple. The folds of the branchiæ eight in number, four on each side, and the meshes uninterrupted. Intestine strengthened by a cylindrical rib from the pylorus to the anus. Liver absent or indistinct.

Genus, *Styela*.—Ovarium divided, one division at least on each side. *S. Canopus*. Sav. *Tab. viii. f. 1.*

Genus, *Pandocia*.—Ovarium single, and situate in the fold of the intestine. The *Ascidia conchilega*, a native species, is the type.

2. Apertures with indistinct rays, or more than four.

The external tunic is here soft, easily cut, and translucent. The rays (when existing) of the branchial orifice amount to eight or nine; and those of the anal to six at least. The branchiæ are destitute

of longitudinal folds. The tentacular filaments of the branchial circle are simple. Liver indistinct. Ovarium single.

a. Body pedunculated.

The stalk is here placed at the base, and serves to support the body, being of an opposite character from that of the *Boltenia*.

Genus, *Clavelina*.—Branchial and anal orifices without rays. Angles of the branchial meshes simple. Intestine destitute of a rib. The *Ascidia clavata* of Pallas, and the *A. lepadiformis* of Muller, belong to this genus; the latter of these is now recorded as a British species.

b. Body sessile.

The branchial orifice with eight or nine rays, and the anal with six. The angles of the branchial meshes with papillæ. No liver. A cylindrical rib extending from the pylorus to the anus.

(A.) Tunic and branchial cavity straight.

Genus, *Pirena*.—The branchial sac as extended as the tunic. Stomach not resting on the intestine. *P. phusca* of Forskael is the type, to which Savigny has added three other species. The *Ascidia prunum* of Muller, a native species, is probably of this genus.

Genus, *Ciona*.—Branchial sac shorter than the tunic, and exceeded by the viscera. *C. Ascidia intestinalis*, Lin. is a native example of this genus.

(B.) Tunic turned up at the base.

Genus, *Phallusia*.—Branchial sac extending beyond the viscera into the pouch of the sac. Stomach resting on the mass of viscera. The *Ascidia mentula* of Muller, a native species, is the type.

There are two genera supposed to be nearly related to the preceding, which are involved in great obscurity. The genus *Bipapilaria* of Lamarck appears to be pedunculated, with two apertures, each furnished with three setaceous tentacula. The *Mammaria* of Muller has only one terminal aperture. One species inhabits the British seas.

B. Compound.

The animals included under this division were formerly included in the genus *Alcyonium* of Linnæus, and placed among the Zoophytes. They are compound animals, many individuals united by a common integument, and arranged according to a uniform plan.

In some cases, there is only one system of individuals in the mass, in other cases, there are many, similarly arranged and contiguous. The tentacular filaments of the branchiæ appear to be distinct. They are destitute of the intestinal rib which occurs in some of the preceding genera.

1. Branchial Orifice Radiated.

a. Branchial and anal orifices, with six rays.

(A.) Body sessile. The angles of the branchial meshes furnished with papillæ. The thorax, or cavity containing the branchiæ, cylindrical. The abdomen is inferior, with a stalk. Ovarium sessile, and single.

Genus, *Diazona*.—Body orbicular, with a single system of animals disposed in concentric circles.

The substance is gelatinous. The ovarium an-

Mollusca. closed in the fold of the intestine. *D. violacea* of Sav. Tab. ii. f. 3.

Genus, *Polyzona*.—Body polymorphous, with many systems disposed subcircularly.

The body is subcartilaginous. The individuals are disposed irregularly around the common centre. Savigny inadvertently termed this genus *Distoma*, a name long precopied among the *Intestina*. The *Alcyonium rubrum* of Plancus, and the *Distomus variolosus* of Gaertner, belong to this genus. The last is a native species.

(B.) Body pedunculated.

Genus, *Sigillina*.—Body a solid cone, consisting of a single system of many individuals, irregularly disposed, one above the other.

The thorax is short, and hemispherical. The angles of the branchial meshes destitute of papillæ. The abdomen is inferior, sessile, and larger than the thorax. The single ovarium is pedunculated. *S. australis*, Sav. Tab. iii. f. 2. brought from New Holland, by M. Peron, is the only known species.

b. Branchial orifice only furnished with six rays.

(A.) Body pedunculated. System single, circular, and terminal.

Genus, *Synoicum*.—Anal orifice rayed.

The body is cylindrical. The anal orifice has six very unequal rays; the three largest forming the external margin of the central star. The stomach is simple. The angles of the branchial meshes destitute of papillæ. Ovarium single, sessile attached to the bottom of the abdomen, and descending perpendicularly. The *S. turgens* of Phipps is the type. In the month of August 1817, we observed at the Isle of May another species, adhering to a rock, and differing from the *turgens* chiefly in the smoothness of its skin.

Genus, *Sydncum*.—Anal orifice simple and tubular.

The body is inversely conical. The stomach surrounded with glands. Intestine spirally folded. Ovarium pedunculated. The *S. turbinatum* is the only known species, and was sent to Savigny by Leach from the British seas.

(B.) Body sessile, polymorphous.

• (a.) Each system with a central cavity.

Genus, *Polyclinum*.—Systems numerous, convex stellular. Individuals arranged irregularly round the common centre. Abdomen inferior pedunculated, and less than the thorax. Ovarium single, pedunculated, and attached to the side of the abdominal cavity, and drooping.

M. Savigny describes one species from the Mauritius, and five from the Gulf of Suez.

(b.) Systems destitute of central cavity, and the angles of the branchial meshes without papillæ.

Genus, *Alpidium*.—Individuals in a single row round the common centre.

The thorax is cylindrical. The abdomen inferior sessile, and of the size of the thorax. Ovarium single, sessile, placed at the bottom of the abdomen, and prolonged perpendicularly. Savigny divides the genus into two tribes. In the first, the individuals are simply oblong, with an ovarium shorter than the body, as *A. ficus* (*Alcyonium ficus*, Linn.). In the

second, the individuals are filiform, with an ovarium longer than the body, as *A. effusum* of Savigny, Tab. xvi. f. 3.

Genus, *Didemnum*.—Individuals in indistinct systems.

The thorax is short and subglobular. The abdomen inferior, pedunculated, and larger than the thorax. The anal opening is obscure. The ovarium is single, sessile, and placed on the side of the abdomen. *D. candidum* and *viscosum*, from the Gulf of Suez, are the only known species.

2. Branchial Orifice simple.

The species form a thin fleshy crust on stones and sea-weeds. The individuals are stellularly arranged in distinct systems. The branchial orifice is circular and undivided. The abdomen is sublateral, and fixed at the bottom of the branchial cavity. The intestine is small, and the anus indistinct. The angles of the branchial meshes are without papillæ.

Genus, *Botryllus*.—Systems furnished with a central cavity.

The systems are prominent, and consist of one or more regular concentric rows. The ovarium is double, being attached to each side of the branchial sac.

This genus is subdivided by Savigny into *Botrylli stellati*, and *Botrylli conglomerati*. In the first, where the individuals are distributed in a single row, there are some species in which the individuals are cylindrical with approaching orifices, and the limb of the central cavity not apparent after death and probably short, as the *B. rosacinus Leachii* and *Borlasi*. In other species, the individuals are ovoid, with remote orifices, and the limb of the central cavity is always apparent and notched, as *B. Schlosseri stellatus*, *gemmerus*, and *minutus*. In the *Botrylli conglomerati*, in which the individuals are disposed in several rows, there is only one species, *B. conglomeratus*.

Genus, *Eucælium*.—Systems destitute of a central cavity.

The individuals are distributed in a single row, and the ovarium is single, sessile, and attached to the side of the abdominal cavity. The *E. hospitium* of Sav. Tab. iv. f. 4, is the only known species.

2. Tribe.

Body free, and moving about in the water.

Genus, *Pyrosoma*.

The body is gelatinous, in the form of a lengthened bag open at the widest end. The individuals are arranged perpendicularly to the axis of the central cavity, super-imposed on one another. The branchial orifice is external, without rays, and with an appendage over its upper margin. The anal orifice is opposite, and terminates in the central cavity. Branchial sac destitute of folds, with a membranaceous ring at the entry. The branchiæ are disjointed. The abdomen is inferior to the branchiæ, and not separated by any contraction. Liver distinct, globular, and retained in a fold of the intestine. Ovarium double, opposite, and situate at the upper extremity of the branchial cavity.

M. Savigny divides the species into *Pyrosomata*

Mollusca. *verticilla*, having the individuals arranged in regular prominent rings, as *P. elegans* of Lesueur; and *Pyrosomata paniculata*, having the individuals forming irregular circles unequally prominent, as *P. giganteum* and *Atlanticum*.

2. Subdivision.

Inner tuniæ adhering throughout to the external one.

The body is gelatinous, transparent, and simple. The branchial cavity is open at both ends, communicating freely with the anus. The branchial orifice is in the form of a transverse slit, with one edge in the form of a valve, to accelerate the entrance of the water into the cavity. The inner tunic is strengthened by numerous transverse muscular bands, which, by contracting, diminish the diameter of the cavity, and eject the water from the anal orifice, thereby propelling the body through the water. The digestive organs are situate at the inner end of the cavity. The mouth and rectum are simple; the former placed between the two branchiæ, the latter directed towards the anal orifice. The heart is contiguous to the stomach, at the bottom of what may be termed the branchial sac, and is enveloped in a membranaceous pericardium. The branchiæ are double, not incorporated with the walls of the sac, but with two folds of unequal length. The largest is free in the middle, fixed at each extremity, and opposed to the dorsal groove, and traverses the cavity obliquely. The other extends from the base of the first to the extremity of the dorsal groove. The surface of the branchiæ consists of transverse vessels in a single range in some species, and a double range in others.

When young, many individuals often adhere, and

form chains and circles. But the fully grown individuals are always detached and single. Mollusca. /

This subdivision comprehends the species of the genus *Salpa*; they are exceedingly numerous, and appear to belong to many different genera. M. Cuvier has given indications of some of these, chiefly derived from the shape. A few are furnished with an elevated crest or fin, as the *Thalia* of Brown; a few have both extremities rounded or truncated, as *Salpa octofera* of Cuvier; others have one extremity produced, as *Holothuria zonaria* of Gmelin; and even both extremities produced, as *Salpa maxima* of Forskael. The *Salpa moniliformis*, so common in the Hebrides, and first recorded as a native by Dr Macculloch, in his valuable *Description of the Western Isles*, Vol. II. p. 188, and imperfectly figured in its young state, at Tab. xxix. fig. 2, appears to be closely allied to the *S. maxima* of Forskael, and but very remotely with the *S. polycratica* and *confederata* with which it is compared. This observer states, that "It cannot bear to be confined in a limited portion of water, as it died even in a ship's bucket in less than half an hour." With us, in similar circumstances, those taken in the evening were alive at noon on the following day.

The preparation of molluscous animals for exhibition in a museum is attended with peculiar difficulty. The shells, indeed, need only to be cleaned with a soft brush, and the marine kinds to be steeped in fresh water to extract all the saline ingredients, and dried, when they are fit for the cabinet. The soft parts, however, can seldom be distended by any substance, and dried. They are usually, therefore, preserved in spirits of wine, where but too frequently they appear a shapeless mass. (q. q.)

ERRATA.

VOLUME FOURTH.

- Page 470, col. 2, line 55, for "Unterthancer," read "Unterthanen."
 — 513, col. 1, line 25, for "Almadon," read "Almaden."
 — 519, col. 2, line 27, for "Ocasia," read "Ocana."
